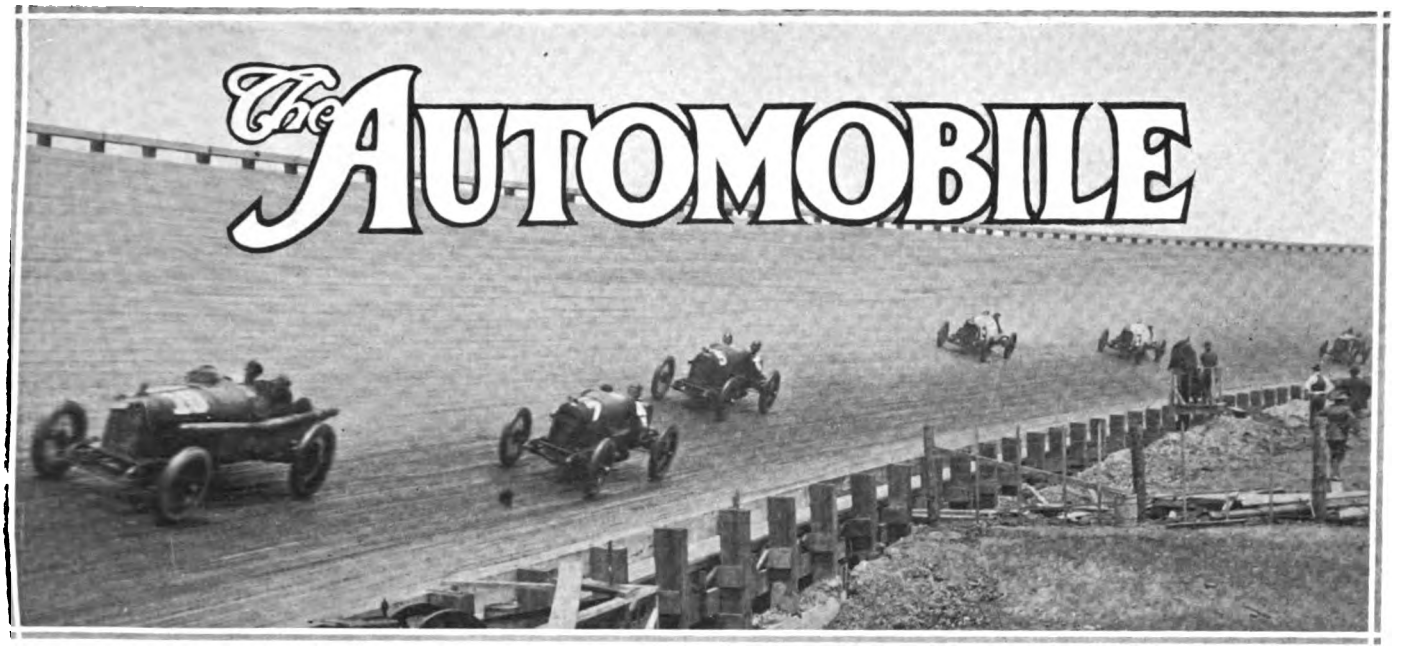
VOL. XXXIII NEW YORK—THURSDAY, JULY 1, 1915—CHICAGO No. 1



Turning the banked curves at 100 miles an hour; a group of contestants at high speed

Resta in Peugeot Victorious

Averages 97.58 Miles Per Hour Over 500-Mile Course on Chicago's Board Saucer—First Ten Higher than 90 Miles Per Hour

CHICAGO SPEEDWAY, June 26—Lacking but 7½ min. of averaging 100 m.p.h. for 500 miles, on the new 2-mile board speedway here to-day, Dario Resta in the Peugeot car in which he finished second at Indianapolis, carried off $23,000 in cash prizes, and set a world's record for this distance on any speedway. This average might have been higher had he been forced to extend the Peugeot, in fact during three of the centuries out of the five hundred, the average was over 98 m.p.h., the highest average being on the second hundred mile where Resta put the mark at 99.4 m.p.h.

Believed 97 M.P.H. Would Win

A speed of 97.58 m.p.h. was not dreamed of previous to the start of the race. Resta himself believing that a pace of 97 m.p.h. would easily win. With this object in view he set out not to hurry himself during the first hour, when his average was 96.8 m.p.h. This proved too slow and he found himself in third position and 1½ min. behind Porporato in a Sunbeam who was setting the pace. This brought Resta to the realization of the fact that to win meant a higher speed than 97 m.p.h. and he started his second century with 100 m.p.h. as his objective. How close he came to this is shown by the timer tape which gives his average for the second hundred at 99.4 m.p.h. at which position he was leading with a little over a minute on the rest of the field. He slackened slightly on the third hundred placing his average at 98.3, but finishing this century with a lead of over 3 min. His fourth century was made at 98.4 m.p.h. at the end of which he had a lead of over 3½ min. He slackened off very considerably during the last hundred miles, when he had the race well in hand, his pace aver-

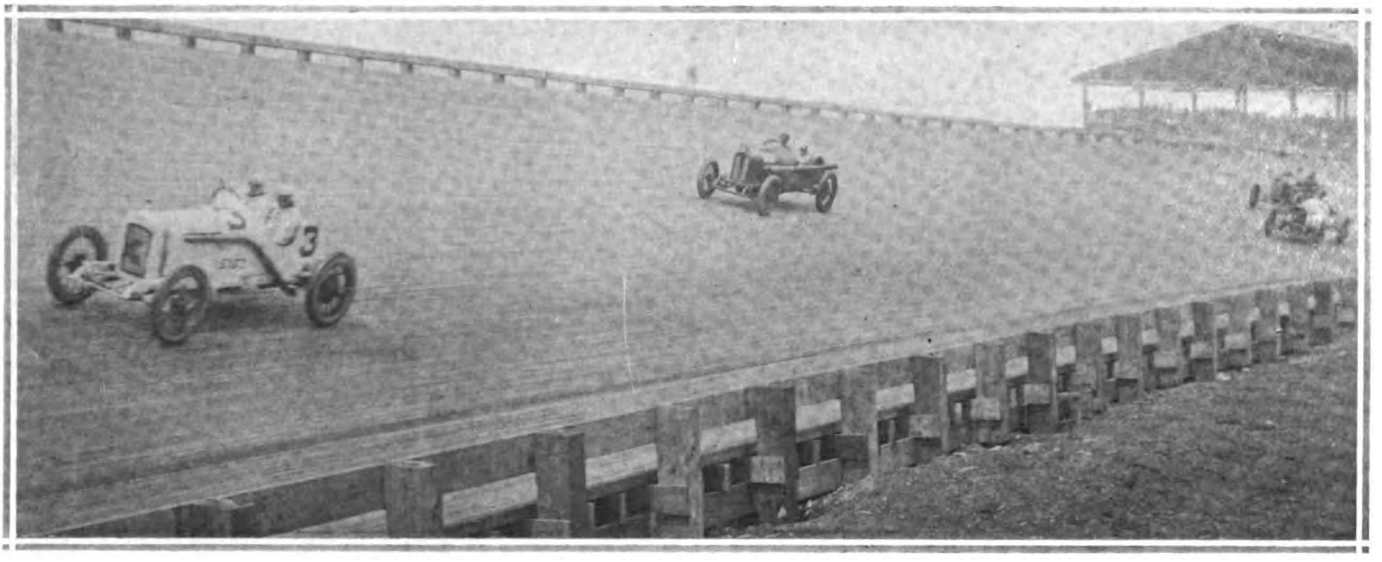
RESULTS

Driver	Car	M.P.H.
Resta	Peugeot	97.58
Porporato	Sunbeam	96.5
Rickenbacher	Maxwell	96.1
E. Cooper	Stutz	94.9
Grant	Sunbeam	94.3
Anderson	Stutz	93.7
Chevrolet	Delage	92.8
Burman	Peugeot	92.2
Alley	Duesenburg	91.3
J. Cooper	Sebring	90.3



Anderson's Stutz leading Van Raalte's Sunbeam, showing the latter's tendency to go high on the bank

aging but 95 m.p.h. which was enough to let him win with a margin of 3 min. and 24 sec. over Porporato who was in second position with a Sunbeam.

Board Surface Makes Good

The average pace of 97.58 m.p.h. as compared with 89.84 average by DePalma at the Indianapolis speedway, gives some indication of what may be expected in the future on board tracks. Chicago's new board surface has made good to-day in a manner not anticipated by the most sanguine. Cord tires have also made good to-day in a manner that exceeds the expectations of those who saw them perform so remarkably at Indianapolis. Up to 100 m.p.h. these tires gave a good account of themselves but at speeds of over 100 m.p.h. the wear was such as to make changes necessary on the right rear every 15 or 20 min.

Battle from the Start

Resta had to battle with his rivals from the drop of the starter's flag until the race was half over before he was certain of a walk-over, and from that distance to the finish it was largely a procession on his part. The greatest speed of the race was during the first hundred miles when the 3 Stutz cars and Porporato's Sunbeam were setting a pace intended to eliminate Resta's fast Peugeot. An average lap by lap of 105 to 108 m.p.h. was being maintained by these leaders, and if it had not been for tire troubles during the first century a phenomenally high pace would have been maintained. Instead of drawing Resta out, as they had hoped, the wiley Italian stuck to his objective, 97 m.p.h. and watched his competitors one by one stop for tire troubles. Porporato led the field at the end of the first century gaining the distinction of being the first driver to win the $1,000 for leadership at this point. Cooper in the Stutz was second, and Wilcox in another Stutz was eliminated with a broken piston.

It was at this point that Resta's real race started, namely that of overtaking Porporato and Cooper and establishing a safe lead for himself, which he had accomplished before 120 miles were covered. At this point he leading Porporato by 6 sec. At 140 miles his lead was 25 sec. At 150 miles he had a lead of 49 sec. At 160 miles he had nearly 2 min. to his credit, and from this time to the finish he never lost the leadership, while the fight for second place was being steadily waged among Porporato in his Sunbeam, Rickenbacher in a Maxwell, and Earl Cooper with the Stutz at a speed which often went up to as much as 100 m.p.h.

Porporato Forces Pace

Porporato who finished in second position with an average of 96.5 m.p.h. was one of the drivers to greatly improve his chances after the Indianapolis race, where he failed to make a showing. He was but 3 min. and 24 sec. behind the leader at the finish, and his phenomenal performance during the first hundred miles constituted one of the most interesting phases of the race. It was his battle with the Stutzes during this opening century which was responsible for the high average of 99.2 m.p.h. irrespective of many stops for tire troubles as well as the disadvantage of starting with relatively cold motors, which could not be expected to show up as well in the opening century as in subsequent ones. Although leading at the first hundred, Porporato was in second place at 200 miles being more than 3 min. back of the leader; at 300 miles he was back in fourth place, Rickenbacher's Maxwell and Cooper's Stutz leading him by approximately a minute. He ran in fourth position to 350 miles when he got back in third place and was able to get in second position at 400 miles which position he maintained to the finish of the race with the narrow margin of 15 sec. From the time Porporato safely landed in second place at 400 miles, it was a neck-and-neck fight with Rickenbacher who was rapidly gaining on him at the finish. Porporato had a lead of less than a minute on Rickenbacher's Maxwell at 400 miles. He increased this to nearly 2 min. at 440 miles and at 460 miles he had a lead of nearly 3 min. This was cut to less than a minute at 480 and to 15 sec. at the finish.

Prize Winners

No.	Driver	Car	Prizes
1	Resta	Peugeot	$23,000
11	Porporato	Sunbeam	11,000
7	Rickenbacher	Maxwell	5,000
4	E. Cooper	Stutz	3,500
17	Grant	Sunbeam	3,000
3	Anderson	Stutz	2,000
12	Chevrolet	Delage	1,800
9	Burman	Peugeot	1,700
19	Alley	Deusenberg	1,600
23	J. Cooper	Sebring	1,400
	Total		$54,000

Stutz Set Fast Pace

Before the start the Stutz entry of 3 cars was looked upon to be a determining factor in the race and wide regret was expressed by Stutz followers when the first to finish was Cooper's in fourth place and the next Anderson's in sixth position. Wilcox

The last row passes the pits as Resta leads off the first lap

driving the third Stutz was eliminated on the ninetieth mile. From the start the three Stutzes set out to maintain a terrific pace, Wilcox being the pace setter as at Indianapolis. Tire troubles soon set in. The race started at 10.30 and exactly 17 min. later Cooper stopped to change a right rear on his Stutz; a minute later Anderson stopped his Stutz to change a right rear, leaving Wilcox and Resta averaging 104 m.p.h. to the lap. At 32 miles or exactly 19 min. after starting Resta stopped to change a right rear, allowing Wilcox to gain three-quarters of a lap, but his leadership was shortlived as he to had to stop to change a right rear after the race was running but 22 min. He took 30 sec. for the change but which was enough to restore the leadership to Resta.

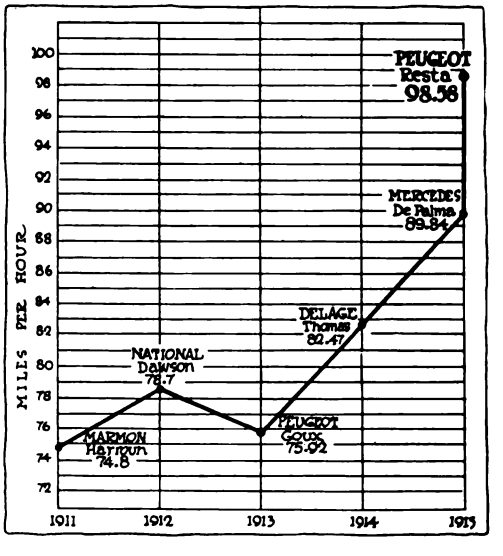
Resta's leadership was again surrendered when at 74 miles he stopped for another right rear, with Wilcox but a lap behind him, and Anderson closely following. At this point it looked as if three or four stood even chances for the $1,000 prize for leadership at the end of the first hundred miles, but stops for tires entirely changed the aspect of affairs, and Porporato carried off the wished for gold.

Rickenbacher's performance in bringing the Maxwell into third position with an average speed of 96.1 m.p.h. was unexpected. He was not a serious contender during the first hundred miles running in eleventh place at 60 miles. He cut this to ninth position at 100 miles. It was in the second century that he established himself by cutting to eighth place at 120, to sixth place at 140, to fifth place at 160, to fourth place at 180, and to third at 220. He dropped back to fourth place for a short time only to later regain third which he held for the last hundred miles.

Earl Cooper brought his Stutz into fourth position finishing with an average of 94.4 m.p.h. Cooper drove a remarkably consistent race from start to finish only for one period during the entire race did he get further back than fourth place, this being between 220 and 280 miles when he was running in fifth and seventh positions. He was soon in third place, but at 350 miles was in fifth which he held until near the finish.

Harry Grant finished in fifth position. To bring his six-cylinder Sunbeam home in that place was considered impossible both by Grant and the others and to bring it home as he did without making a stop was wonderful indeed. The car is old and has been raced many seasons, its speed quite high, but its stamina for a long grind always questioned. Grant turned the 2-mile track in 1 min. 15 sec. to 1 min. 16 sec. as steadily as if some mechanical device were in control. When Grant crossed the tape on his last lap his 7-gallon oil tank was empty, his gasoline was exhausted for he coasted over the line, and many parts of his car were about to give way. The exhaust pipe was broken and the rear half almost dropping off and many other unimportant parts were in equally bad shape. But Grant has been having hard luck with this car for two seasons and in each race started, some minor trouble would develop and put him out of the running. The single set of tires Grant used were Silvertown cords and the front set showed practically no wear, while the rears had only a small portion of the tread ground off. Grant was the only driver to finish the 500 miles without making a stop, but he was not alone in bringing home a car without making a tire change. Five others share this honor with him, Alley, J. Cooper in a Sebring, Orr in a Maxwell, and Mulford and Babcock both of whom finished but not in the first ten.

The five other cars to finish were: Anderson's Stutz, at 93.7 m.p.h.; Chevrolet, Delage at 92.8 m.p.h.; Burman, Peugeot at 92.2 m.p.h.; Alley, Duesenberg at 91.3 m.p.h., and J. Cooper, Sebring at 90.3 m.p.h.



Speed chart showing big gain in miles per hour above previous events

Burman Changes a Piston

Of those finishing in the money there is another whom we must acknowledge as displaying gameness of an unusual sort, this being Burman. Thirty minute before the official time for starting Burman discovered a piston had seized momentarily during his last trial lap and this meant he was out of the race unless Referee Vissering would grant him time practically to dismantle his motor. The drivers and officials expressed their willingness to have the start delayed until 10.30 to allow Burman to replace the burned piston and clean the scored cylinder. With a trio of

24	Ogren	Chandler	Out	24th mile,		broken bevel pinion housing.													

mechanics Burman set to work and with lightning speed dismantled the motor, cleaned the cylinder by lapping in a dummy piston with coarse emery, replaced the injured piston and was ready on the starting line at 10.30. It was remarkably fast work and efficient too, as it proved when Burman finished in eighth place.

Porporato Breathed Smoke

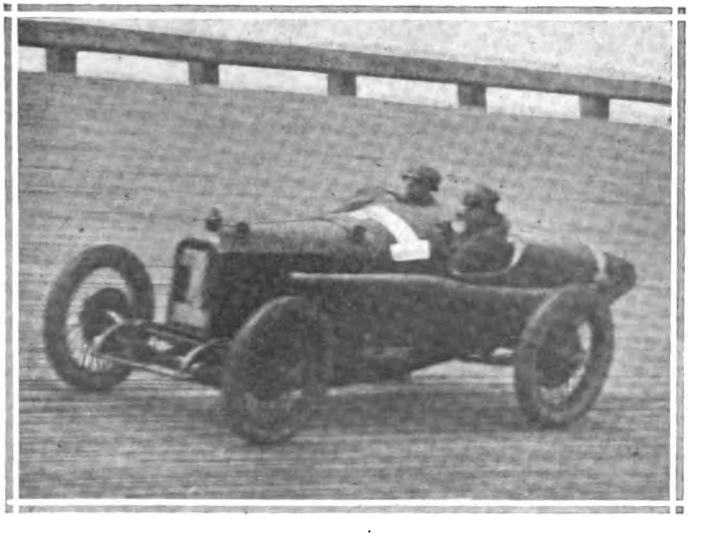
Those knowing the drivers intimately, realize the astonishing results. While it was not unexpected that Resta would win, for he had the fastest car in the race, it was unlooked for to see Porporato, and Rickenbacker finish as they did, since these contestants were expected to be displaced by the Stutzes. Porporato was a happy place winner, for before the race he expressed himself as believing his car would not finish. "It cannot stand the terrible grind which I expect will be over 95 m.p.h." But Porporato gained hope when he was told he was running two laps behind Resta for about 50 miles. And atop of it all Porporato drove through the entire 500 miles in an atmosphere of smoke. This was caused by discharges from the breather pipe and leaks about the exhaust pipe, the smoke being forced through the driver's compartment by an air draught. When asked how he possibly finished after breathing smoke for 5 hours he answered through his interpreter, "Periodically I would stick my head to one side and get a breath of fresh air and this would be enough for one-quarter of a lap."

Other astonishing results were made. It was thought by everyone, that there would be an unusually large number of failures in the early part of the race because of the fast pace anticipated. Many predicted the number of cars to finish would be insufficient to take all the prize money. The first 100 miles showed three cars withdrawn. These were the Ogren driven by Chandler which went out after 20 miles with a broken driving pinion housing, the Mercer special driven by Hanning went out with ignition trouble caused by too loose pistons and the Stutz driven by Wilcox withdrawing with a broken piston. This car mortality was very low compared with Indianapolis where five cars went out early in the race. Between 100 and 200 miles the remaining twenty-one cars all remained in the race, but between 200 and 300 two more fell by the wayside, these being the Sunbeam driven by Limberg which had burned out a bearing and the Duesenberg with Haupt up which went out because the clutch could not be operated.

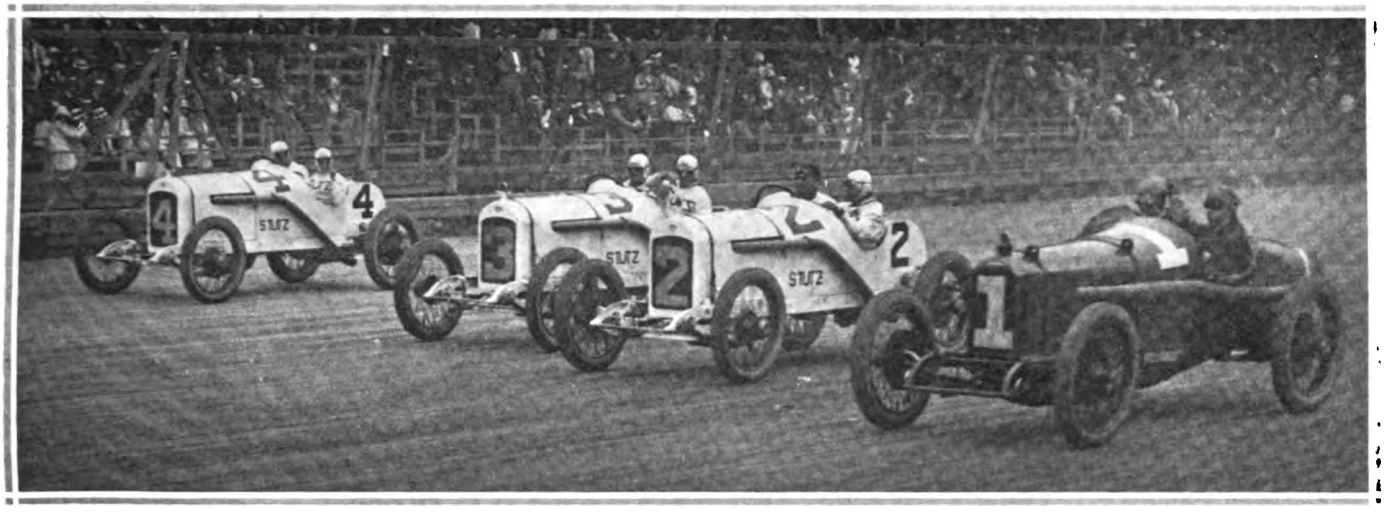
Six failures in twenty-one starters is a very good record and on a percentage basis equals about 29 per cent, whereas at Indianapolis half the field, or eleven cars, were withdrawn before the race was finished.

Track Design Helped Speed

That few cars dropped out and that the time of the first ten was better than DePalma's Indianapolis record was possible only because of the design of the track. Had the cars and drivers been capable of withstanding a speed of 110 m.p.h. the track would have permitted it, for its turns are



Resta traveling at high speed around the course



Front row favorites. Resta's Peugeot and the three Stutz who were expected to make the pace

so shaped as to make steering an act requiring little effort and, if properly negotiated, reduce tire wear to a minimum. Most of the drivers found that high riding, about 8 ft. from the top rail was the tire saving zone while others who traveled low and scraped their wheels across the wood surface made the greater number of tire changes. After 100 miles of running a black band about 10 ft. wide formed from exhaust smoke, oil, water and other drippings from the cars encircled the track and it was at a point just outside this band that tires seemed to ride with least wear. Grant found this out early in the race and while Porporato had an idea that high riding would do the trick, he rode too high and entered and left the turns with too much of a swing. Grant attributed his tire record to three things, the tires, the method of driving and the weight distribution of his car which he redesigned in this respect.

There were many conditions present at Chicago's race which parallel as many at Indianapolis. In the first place the race to-day should have been run last Saturday but rain caused a postponement. One hour before the start, black clouds hovered overhead and it looked as if a storm was approaching, as also at Indianapolis. Even at the start a heavy mist dropped over the track so that grandstand spectators could not see the bleachers opposite, which is possible in fair weather. It was an hour after the start that Old Sol poked his head from behind a cloud and beat down with all his calorific value on the wood saucer. He showed out just in time to brighten Porporato when he crossed the tape a leader at 100 miles at 99.8 m.p.h. and a winner of the $1,000 prize offered for the performance.

Cars Went Through Mist

The twenty-one cars starting plowed through the heavy mist with Resta leading a 100-mile pace. He had to lead for it was expected of him and he was being hounded by the Stutzes. But Resta drove beautifully and suffered no trouble like he did at Indianapolis. He made five stops, three for a right rear tire and two for supplies of fuel and oil. His last stop was made while he was leading Porporato by three laps and evidently Resta remembered the fate of others who lost a race because the car needed fuel on the last lap. Resta has pitmen of par excellence; men who practiced for weeks before, in changing tires, filling the tanks, etc. Resta stood calmly by each time he stopped and even on his last halt he waited patiently for assistance instead of getting excited. Resta did not have to fear Porporato for to gain three laps was impossible at this time and the next nearest man was Rickenbacher who was too far behind even to be considered

General view of the activities at the track during the 500-mile race at the Chicago speedway

a more than barely possible snatcher of Resta's position.

It seems odd that the second and third finishers also should have made five stops each. Porporato halted four times for tires and once for supplies. Three stops for tire changes were made within 48 min. The first at 92 miles, the second at 150 and the third at 158 miles.

Rickenbacher's five stops were divided as Resta's, three for tires and two for supplies. As with Resta, Rickenbacher halted early in the race—once at 26 miles, but his last stop was made at 341 miles.

At the start of the race Resta was worried, and he had reason to be, because every driver in the race looked to him as the man to "get." All sorts of plans were afoot and it appears that the three Stutzes attempted to arrange themselves in a row directly behind Resta so that at a certain moment the picked one would shoot out in the lead. Wilcox did the trick and jockeyed with Resta for about four laps and then had to stop for a tire change. However, Resta stopped a few laps later for a tire, and this allowed Wilcox to come around and take the lead, with Resta just starting out from the pits. Meanwhile Cooper and Anderson were fighting hard to get Resta's lead and Porporato was undecided as to what to do. At 50 miles Resta was leading by only a small margin and a few knew where Porporato was running. Between 50 and 100 miles Resta held the lead practically all the time, but Porporato unknowingly shot ahead at 100, taking the $1,000 prize and the record for the distance.

From 100 miles onward Resta had his own way. He had from two to ten laps on the majority of the field and only two Stutzes and Porporato to contend with as the others did not care to break up in an effort to get further in front. These in the ruck relied upon the failure of the leaders to set them ahead. It was Resta, Porporato, Rickenbacher and Cooper who were doing the fast work in front. Porporato did not know what position he held because the scoring was not up to standard, but he was so enthusiastic because the car was still on the course that he was content to keep going and merely finish. At 200 miles Resta was traveling slightly under 98 miles per hour, taking the turns rather high and coming around so often that spectators started to lose track of the number of laps he was ahead of the others. Strange as it may seem, it looked as if Porporato was traveling faster than Resta, probably because the former was driving close to the wall on the straightaway and offered better comparison with a fixed object. However, Porporato was running in third place about 3 min. behind Resta and following him was Cooper, only one lap behind, and Rickenbacher, almost on even terms with Porporato.

Four Drivers Furnish Thrills

These four drivers were furnishing the spectators with a demonstration of the speed capabilities of the track and at 300 miles the order was changed with Rickenbacher in second place 5 min., or nearly 4 laps, behind Resta. Cooper was third and Porporato was fourth. It was after the 300 mile mark that Porporato began to wake up and at 400 he was in second place. These four men ran the last 100 miles in practically the same order they showed at 400, but each worked hard to gain a little, all succeeding, as the times show.

When the first ten men had finished there still were five cars on the track and each one wanted to finish.

In point of attendance the speedway officials were satisfied and an official count showed 80,000 people had paid for watching the first 500-mile race in Chicago. Many of the spectators did not arrive until a few minutes before the start owing to the fact that the Illinois Central Railroad was blocked for more than three miles because of a wreck. This was the only steam road running special trains to the speedway and its service was paralized completely for more than two hours. The roads leading to the track were frightfully crowded with pedestrians and automobiles, not a few cars being forced into the ditch and pulled out by teams.

Race Motors Behave Marvelously

Anticipated Failures Due to High Speeds Do Not Occur—Cars Well Prepared After Indianapolis Race

By A. Ludlow Clayden

CHICAGO SPEEDWAY, June 26—Everyone, whether layman or expert, was agreed that the extremely high speed capability of the Chicago speedway would provoke motor trouble, and prophets were not wanting to predict that the speed made at Indianapolis would not be beaten; simply because the cars would not stand up under treatment any more severe. Well, the events of today prove that the prophets were wrong as they have often been before in racing predictions.

Of the cars which finished well up in the list the first eight had nothing done to their motors throughout the race. Burman, the ninth man, changed a couple of spark plugs on two occasions and the tenth man never touched the motor at all. Thus out of ten cars all running 500 miles at a speed in excess of 90 miles an hour, a total distance of 5,000 car-miles, all that was done to the ten engines was the changing of four spark plugs.

Let us look at the total of reliability which this represents.

Forty ultra-light pistons stood up.

One hundred and forty valves and valve springs stood up.

Ten magnetos supplied at least 18,000,000 sparks.

Not more than sixty spark plugs took this discharge and stood up (probably those which Burman changed were missing because of oil).

Eleven carbureters gave a steady supply of proper gas.

Oil in proper quantities reached the 1,000 moving parts of the ten motors.

And, this is the main point of the whole demonstration:

Only two modern design cars suffered broken parts, despite such a thrashing as a bunch of racing machines has never before received.

Lessons of Indianapolis

Now, it is not very long since the Indianapolis 500-mile race showed a very different state of affairs, so there can be no question that the lessons learned in the Hoosier classic have been taken to heart, and that the time interval has been sufficient to enable the owners of the competing vehicles to make good use of their experiences.

At Indianapolis two things stood out prominently as troubles, spark plugs and materials. Both these in turn reflect to lubrication for the spark plugs which failed to spark mostly did so because of too much oil, while the materials which, in the forms of pistons or connecting rods, could not stand the stress mostly failed because absence of oil at the right place produced too much friction and so too much heat.

This was not always so for some of the mechanical breakdowns at Indianapolis were caused by too weak a design, such as the use of too fine a fillet between the head and the wall of an aluminum-alloy piston. Such things as this have been changed, the oil pressures have been adjusted, the piston clearances have been modified so as to give the best compromise of freedom and oil tightness, in one or two cases compressions have been altered and valve spring strengths have been increased a little on some of the cars, but nothing radical has been done.

Racers Are Improved

One might sum up the whole situation by saying that Indianapolis showed us a bunch of fine cars either altogether new or partly new. Cars prepared with the utmost care but not tried out under the only really severe test, that of a long race.

At Chicago we have now seen the same cars freed from their minor faults, with the bugs removed. They are to the cars of 4 weeks ago as the stock product of a good manufacturer is to his last experimental model and this record-breaking race in Chicago is the finest testimony that the world of motoring has ever had to the importance of little things. One thing and one thing only made the motors' task a little easier and this was a general use of slightly higher gear ratios, but this was offset or even more than nullified by the greater speed and the much higher air temperature.

Belgian Armored Cars Most Efficient

Organized into Corps of Two Sections Each—Observation, Ammunition and Supply Cars, Cyclists and Motorcyclists in Each Unit

By W. F. Bradley
Special Representative of THE AUTOMOBILE, *with the Allied Armies in France*

IT is a somewhat curious fact that when the European war broke out the application of the automobile to warfare was decidedly inferior to the industrial and commercial organization of the self-propelled vehicle. Because staff officers made use of cars in place of horses, and because the aeroplane industry had been absorbed by the military authorities, it was popularly supposed that everything worth knowing about military motoring was possessed by the army authorities. As a matter of fact, military officers in all countries are the most conservative of beings. During the 8 months the war has been in progress more prejudices have been scattered to the winds, more practical knowledge has been gained and more progress has been made in the application of the automobile to military operations than in the 8 years preceding August 1, 1914.

Before the War

Germany, with her wonderfully efficient war machine, had not foreseen the full scope of the automobile in a great war. France had enough imagination to see that gasoline must replace oats in the task of carrying food and ammunition to the men in the front line. England possessed the finest fleet of commercial vehicles the world has ever seen and a war office which did not actually own more than a score of trucks when it was decided to send an army across the Channel. Belgium was snug and smug in her neutrality and had not even taken the trouble to consider in what way her motor industry could be of use to her army.

It is thus all the more to the credit of the plucky little nation that she should at the present time have the most carefully developed and the most efficient fighting automobile corps to be found in Europe. Even to the non-military mind it is obvious that the best use of the armored automobile is not as an individual machine attached to an infantry battalion or a cavalry regiment. To carry out really important work the armored automobiles must form a homogeneous and self-contained corps capable of operations on a really important scale. Such a corps, as it exists at the present time in the Belgian army, comprises ten cars fitted with cannon and machine gun and protected by armor plating, three officers' armor plated observation cars, one automobile workshop, two ammunition cars, three supply cars with gasoline, tires, oil

One of the Belgian armored cars as it appears on the road

and mechanical spares, and one automobile ambulance. In addition the corps has attached to it 100 cyclists and twelve motorcyclists.

A corps of this nature is divided into two sections, each comprising five armored cars, one officers' observation car, one ammunition car, two supply cars, fifty cyclists and six motorcyclists. The third observation car is used by the corps commander whether the two sections are working together or separately, while the repair car and the ambulance are common to the two sections. There is also an ordinary touring car used for despatch carrying and general work. The twenty-one cars forming the armored corps carry about 100 men, thus with the cyclists and motorcyclists making a total of more than 200 officers and men.

Each Man a Specialist

The staffs are picked with special care, every man being a specialist in his particular task. Every driver has had long experience on the road; the gunners are the best the army can provide; the men on the repair car can be relied on to make good anything short of a complete smash; there is an expert electrician for the electric lighting equipments; every motorcyclist can do running repairs and the cyclists comprise many professional road racers.

The corps has been organized and the cars designed and produced by Belgian automobilists of long experience, in collaboration with army officers. In this work the automobile engineer played a much more important rôle than the military expert, although it is obvious that the best results could only be obtained by a reasonable co-operation between an army man convinced of the utility of the automobile and an expert automobile engineer knowing what features to emphasize and what mistakes to avoid in order to get the most efficient service. To give complete credit, it should be mentioned that the artillery officer had to find a place on the expert committee, his task being to design the mounting of the guns and the armor plating on the cars.

Two makes of cars are used, the majority being 20 horsepower Mors, with Knight motor, and the others 18 horsepower Peugeots with four-cylinder, poppet-valve motors. The Peugeot cylinder dimensions are 3.7 by 6.3 inches, and the Mors bore and stroke are 3.9 by 5.5 inches. The two makes of cars are practically equal in speed and weight carrying capacity. They are all fitted with wire wheels carrying tires of 880 by 120 millimeters, the armored cars having twin wheels at the rear, and all the others have singles back and front. By this arrangement only one size wheel and one size tire is made use of in the entire corps, thus simplifying the carrying of supplies.

Every Detail Complete

No detail in the design and fitting up of the cars has been overlooked. The Mors armored cars have a single compartment built of 5 millimeter steel plate capable of resisting a rifle bullet fired at comparatively short range. A partial roof is fitted over the head of the driver, but is capable of being hinged forward so as to give easier movement within the body. There is no door, the men climbing in over the sides. The gun is mounted on a steel platform at the rear, its base swinging round on the platform, so that it is possible to fire ahead, astern, to left, or to right. One of the distinctive features of these cars is the use of the ordinary machine gun taking the rifle cartridge, and also of a cannon of practically 40 millimeter bore. The quick firer is mounted immediately above the cannon, in such a way that the gunner can use either one or the other at will, but in addition the rapid firing gun can be unshipped, fastened in supports on the side of the car and used in one direction while the bigger gun is firing in another direction.

The driver is placed as low as possible, with a sloping roof over his head, the hinged screen within this roof being

Above—Belgian armored car which has received its colors prior to leaving for the front

Below—Rear view of Belgian armored car. Note cannon and quick-firer above it; also tool chest at rear with axe and spade fastened at the side

capable of being placed at any angle so as to give a more or less clear view of the road. When closed down entirely, the driver has a view ahead through an eye hole only. There is a small shuttered opening on the two sides of the car, level with the heads of the driver and his assistant, and on the outside of these a mirror enabling a view to be obtained of what is happening immediately to the rear. Although there is but one steering wheel and one set of controls, there are two sets of clutch and brake pedals, the auxiliary set being in front of the reserve driver. As the switch is also centrally located, it is possible for the relief man to stop the car if the man at the wheel should be shot.

Protection of the motor comprises a fixed steel plate in front of and around the sides of the radiator, and steel plates received in grooves, on each side of the hood. The top of the hood is not protected. The steel guard in front of the

radiator has six rectangular openings cut in it, with a steel plate carried in front of the opening, there being a gap of about an inch and a half between this plate and the main surface. In addition there is a wind scoop at the top and bottom of the radiator guard. Two ventilator cowls are fitted on the top of the hood to help carry away the hot air from the motor. It has been found that this design gives adequate cooling, while protecting the motor without interfering with accessibility. Naturally a pump and ventilator fan are carried. In order to attend to magneto, carbureter or valves it is only necessary to lift out the sliding side plates and raise the hood in the usual way. Gasoline and oil are carried in the cowl, and thus fully protected against shot. The body stops short just a little ahead of the rear axle, leaving a space at the rear for a locker divided into six compartments for tools and spares. Other spares are strapped to the top of this locker, while on the sides are an axe, spade, saw and hammer, and on one side of the frame member, partly hidden under the body overhang, there is a pick and big shovel. On the right-hand side of the body there is a spare wheel carrier.

Lighting System Complete

Lighting equipment comprises a dynamo under the floorboards, supplying current to lamps within the car, to the headlights, and to the side lamps. The headlights are, however, also fitted up for acetylene, the generator being mounted on the left hand side of the body, just to the rear of the hood. The side lamps have gasoline burners in addition to the electric bulbs. It is practically impossible for the cars to be held up for lack of light. If the electric headlights fail the bulbs are taken out and the acetylene generator put into action. If there is no electric current, the gasoline side lamps can be used. It is because gasoline is always carried on the car that it has been preferred to kerosene or oil. Each car carries four men—two gunners, a driver and a reserve driver.

The Observation Car

One of the most interesting units of the section is the observation car. This is an armor-plated car with the body divided into three compartments. In the first compartment are the driver and his assistant, their protection against fire being practically the same as that of the men in the fighting cars. Back of the driver's cab is a small armor-plated compartment just big enough for two men. It has a conning tower in the roof, the sides of the tower being hinged in five or six sections so that one section only can be used if necessary. It is from this car that the commanding officer and his lieutenant command the operations. He makes use of a periscope in the conning tower, and has at hand maps, compass and other instruments. His compartment is fitted up with a seat for two, a folding table, and a series of lockers under the seat. The rear portion of the car is made to carry four men, but is more often used for transporting officers' kit. The entrance is at the rear; this portion of the body is not armor plated.

A Motor Workshop

Although the motor workshop is not as complete as the traveling shops attached to the big motor convoys, it is a really excellent example of a repair department capable of keeping pace on the road with comparatively fast machines. Unlike the convoy workshops, the possibility of overhauling a gearbox or a rear axle has not to be considered. The automobile has a van type body, fully opening at the rear. The equipment comprises a pedal-operated drilling machine, a forge, a heavy vise, anvil, complete sets of taps and dies and a very complete selection of hand tools. On one side of the car is a stout workbench, folding up against the body when not in use, and the tool chests are stout wood lockers fitting all around the car when the vehicle is in motion, but capable of being taken out and placed on the ground so that the top forms a convenient workbench.

There are no special features about the ammunition vans. The supply cars are distinctive, for the van type bodies are divided internally into sections to receive the 6-gallon circular

Lozier's Car a Twelve

Former Manufacturer Breaks Retirement with Announcement of H.A.L. Car—Cylinders in Blocks of Six at 60 Degrees

Harry Lozier's new car to be known as H. A. L.

DETROIT, MICH., June 26—Harry A. Lozier's new car is to be a twelve-cylinder machine, selling at $1,750 either as a two-passenger roadster or seven-passenger touring car. The name selected temporarily is H. A. L., and this may or may not be adopted permanently. Details as to the personnel of the company, which has been organized by Mr. Lozier to market the new twelve in Cleveland, are still withheld.

Since his retirement as the head of the former Lozier Motor Co. in 1912, Mr. Lozier has been carefully studying conditions in the industry, and has reflected some of his ideas of latest construction and present development in the H. A. L.

The motor is 3 by 4½ in., giving it a rating of about 43.2 hp. S. A. E., and piston displacement of 381.6 cu. in.

The motor is a Cleveland product and of a design that has previously been brought out in types of a less number of cylinders. The cylinders are arranged in V fashion, at 60 deg., with all six of each side cast in a block. The valves are overhead and seated in the removable head which comes off as a unit for each block. The valve rods run up to the rockers in the V, which, due to the overhead-valve construction, permitting of the exhaust manifolds running on the outer side of the cylinder blocks, is free of all apparatus with the exception of the carbureter, intake manifolds, water connections and ignition distributer. This makes a very accessible design, particularly as there is a special means at the top of the cylinders for the adjustment of the valve tappets. The valve parts are inclosed completely.

Cylinders Are Offset

In the connection of the rods to the crankshaft, the cylinders are offset enough so that each two rods are placed side by side on the bearing, a form of construction used in several V motors. The crankshaft has three main bearings, and the single camshaft in the center has a separate cam for each valve, making twenty-four in all. The camshaft is driven by silent chain from the crankshaft. Pistons are very light and made of a special aluminum alloy.

In the lubrication system the oil is forced through the drilled crankshaft and is delivered to the bearings in proportion to the power developed.

Setting the cylinder blocks at 60 degrees leaves room on the sides for the location of the starting and lighting units. A satisfactory turning radius is therefore made possible. The position of the exhaust manifolds on the outer side of the cylinder blocks does not interfere with the accessibility of the electric units.

Details of the chassis are meager at this time, although it is definitely stated that a dry-disk clutch is used, and that the wheelbase is 130 in. Left drive with a hard rubber, corrugated steering wheel; center control of a three-speed gearset; and the use of 34 by 4 tires are features that are also known. In the spring suspension, the cantilever construction is employed at the rear, with the front springs of usual half-elliptic type. The gasoline tank is hung at the rear.

In the general outward make-up of the car, the services of a well-known eastern body maker have been had, and the body design is what might be termed a semi-torpedo, with hood and cowl following the same nearly flat slope. The seats are low, with body sides comparatively high. Upholstery does not come over the sides, which are rounded in latest fashion. The new curve that is much in vogue at the back of the front seat is well worked out.

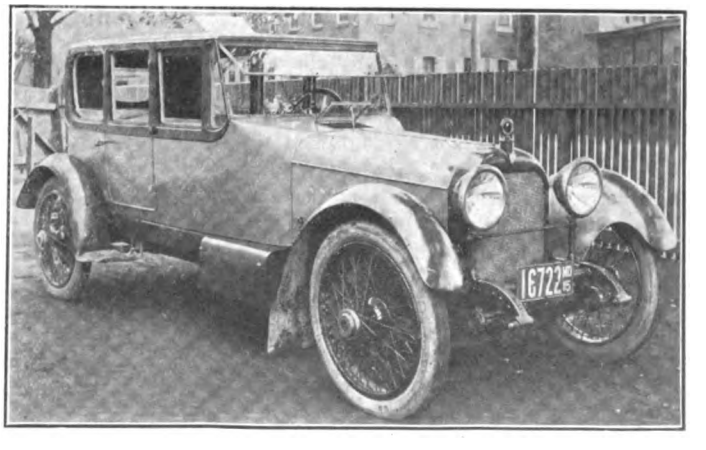
Unique Body on Mercer Chassis

BALTIMORE, MD., June 28.—R. W. Gill of Baltimore is the owner of what is perhaps the most unique closed car ever seen in the Maryland metropolis. It is a specially built Sedan on a 22-70 Mercer Sporting chassis, and embodies many ideas which are decidedly original.

A fair idea of the height of the car can be obtained when it is realized that a man of average height can stand on the ground and look over the top of the car. The seats are exceptionally low, the six-inch cushions resting directly on the floorboards. The front seats are of the individual type, one of them folding up to allow the driver easy access to the front compartment. The interior is decorated in gray whipcord.

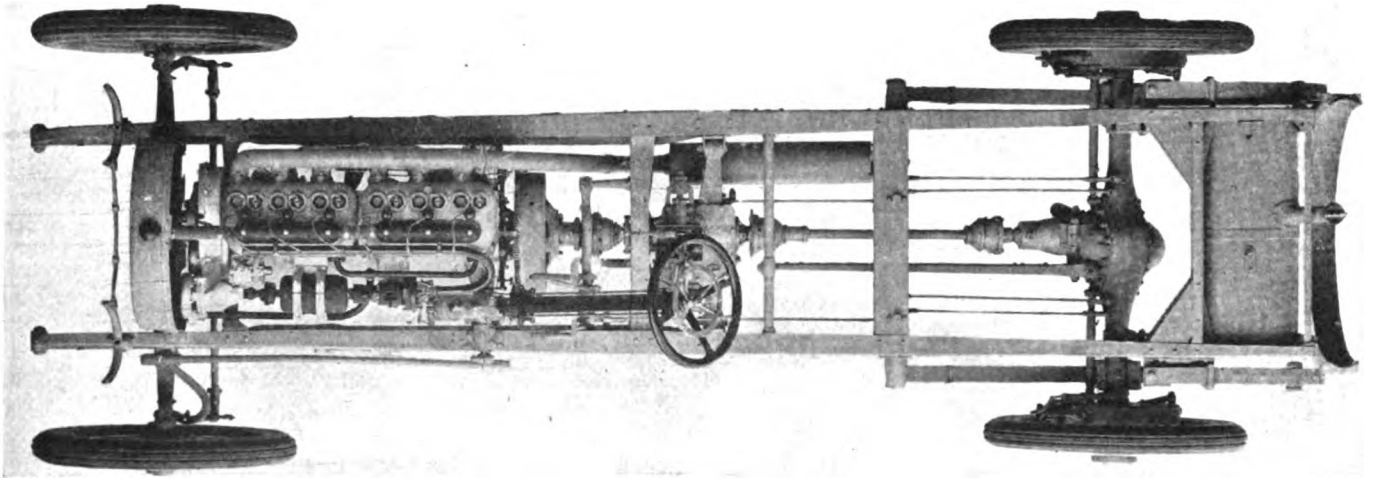
The cowl and roof are fitted with ventilators in the form of small skylight windows. They can be raised or lowered conveniently. On the forward part of the hood Mr. Gill has fitted a small opera light.

The running boards have been omitted, a wide step, suspended from the frame, being used instead. The absence of running boards gives the car a very foreign air, and the various points of individuality, particularly the lowness of the body, are worked out in a way to be especially pleasing.



Unique low sedan body mounted on Mercer chassis

Marmon Features Continued for 1916



Marmon chassis with independent gearset showing method of supporting both motor and gearbox on three points

A Study of the Engineering Principles in the Big Six

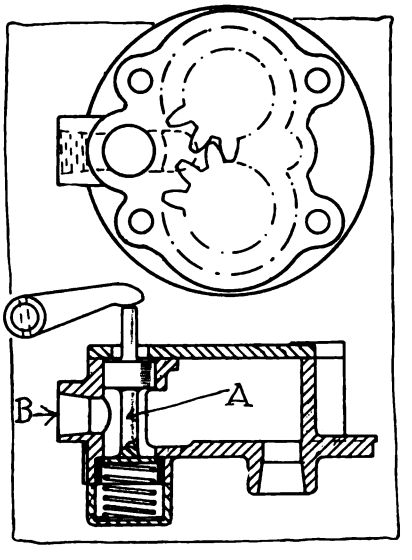
AS already announced in our news columns, the 1916 Marmon six differs but little from the 1915 model, but an examination of the design of the chassis is instructive because there are several Marmon features which have proved good and yet are highly unusual. The chassis as a whole is one of the most original in thought that America is producing to-day.

It is accepted that the running of a six depends upon the rigidity of the crankshaft support to a very great extent and the fact that the Marmon is noticeably free from vibration is traceable to the form of crankcase employed. First, there are seven main bearings on the crankshaft so that each throw has individual support, but this is hardly so important a feature as the way in which these bearings are fitted to the crankcase. In order to provide the maximum of rigidity to the aluminum casting it is made in barrel form. Thus the crankcase is almost the equivalent of a tube, in itself a very strong form to resist bending or distortion. Each of the seven crankshaft bearings is contained in the center of a circular, split-aluminum casting of diameter slightly in excess of that of the crank circle and these seven castings are first fitted to the crankshaft. This makes for a most excellent bearing finish, for the crankshaft can be held in any convenient manner while each bearing in its aluminum carrier is scraped and tested for proper contact. Also the degree of tightness of adjustment of each bearing separately can be tried, which is practically impossible with any other method of crankshaft mounting.

Tubular Crankcase

When all the bearings are in place and fitted properly the whole shaft as a complete unit is put into the crankcase, whereupon the aluminum bearing carriers are bolted in place and add enormously to the stiffness of the whole motor. The crankcase has then become a tube with a series of stiff partitions, a tube reinforced at seven places. It is claimed that the construction is lighter than any other which gives equal rigidity and this is easy to believe since the metal is so well disposed that very little of it can be dead weight; almost every particle of aluminum is doing its share of the work.

In the oiling system there is a novelty which has long been considered by many engineers as being a feature which will ultimately find a place on every chassis. This is an oil throttle which is opened or closed in conjunction with the carbureter throttle so that the pressure of the lubricant varies with the internal pressures in the motor which means that the more heavily a bearing is loaded the more oil is fed to it. Actually the pressure ranges from 12 to 60 pounds per square inch and the way in which this is accomplished is extremely simple. In the drawing on this page is shown the oil pump in section and plan. The little plunger *A* can be depressed by the small lever, and the latter is joined to the carbureter throttle by a straight link rod. As the plunger is depressed the upper piston portion closes the orifice *B* so restricting the oil supply. The spring under the lower part of the plunger is used to return it to the open position and the dumbell shape of piston, of course, equalizes the pressure so that the oil neither tends to open the throttle nor to close it.



Marmon oil pump with throttle which adjusts pressure of oil in accordance with carbureter opening

Oil to Main Bearings

The oil is forced to each main bearing and so gains entry to the hollow crankshaft whence it is conducted to the connecting rod bearings, the piston pins and the cylinders. In addition the camshaft, with its eight bearings, is separately inclosed in an aluminum tunnel which is kept filled with oil under pump pressure, and a tiny hole is drilled through each

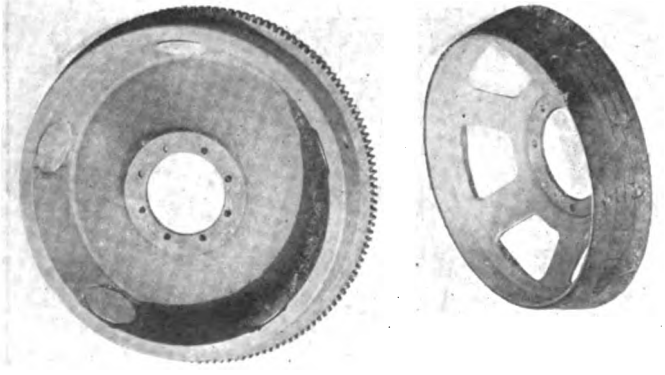
tappet rod. This allows the oil to escape over the head of the tappet immediately beneath the end of the valve stem so lubricating every part of the valve gear, and, it is claimed, the presence of oil at this point quiets the valve action. This is no new feature for the Marmon having been used by the makers for many years, but it is not always that things of this kind are remembered as they should be. It necessitates a tight valve inclosing plate, of course, but there is a large return passage for the oil which lies around the tappets after doing its work, so the cover plates can be removed without any lubricant loss.

Gear-and-Chain Drives

Another somewhat unusual feature is the use of both gear and chain front end drives, the camshaft being driven by a spur gear and the pump or magneto shaft by means of a pair of short chains which run over an intermediate idler for adjusting purposes. This layout is shown in the end view drawing of the motor and it should be observed that it calls for only a small inclosure. Everything is very compact and there is no waste space.

Independent Gearbox

Last year the Marmon company introduced a new clutch with the peculiarity that the cushion springs were located in the flywheel instead of beneath the asbestos cone facing. This feature is continued but it might be well to point out the fundamental advantage. Woven asbestos and wire fabric is heavier than leather and also stiffer, so, to prevent centrifugal force causing it to lift from the cone it is well to secure it as tightly as may be with many rivets. If the clutch cone and facing are thus made as much like one piece as they can be the facing cannot fly out and drag on the flywheel when the clutch is withdrawn. Again, it is easy to fit to the flywheel large area contact springs which give an easier engagement that might be obtained readily from smaller ones beneath the facing material. Of course, the drawback is that it costs a good deal more to machine the flywheel with the necessary recesses for the springs than it would to fit them to the cone.



Marmon clutch with cushion springs set in flywheel instead of beneath fabric facing of cone

Apart from manufacturing considerations there is much to be said for the use of an independent gearbox and there are many who adhere to the belief that it is quieter than any gearset that is in unit with the motor. In the Marmon instance the use of a unit powerplant would be rendered a little difficult on account of the crankcase design so the manufacturers have no regrets in choosing what they consider the better practice of separate parts.

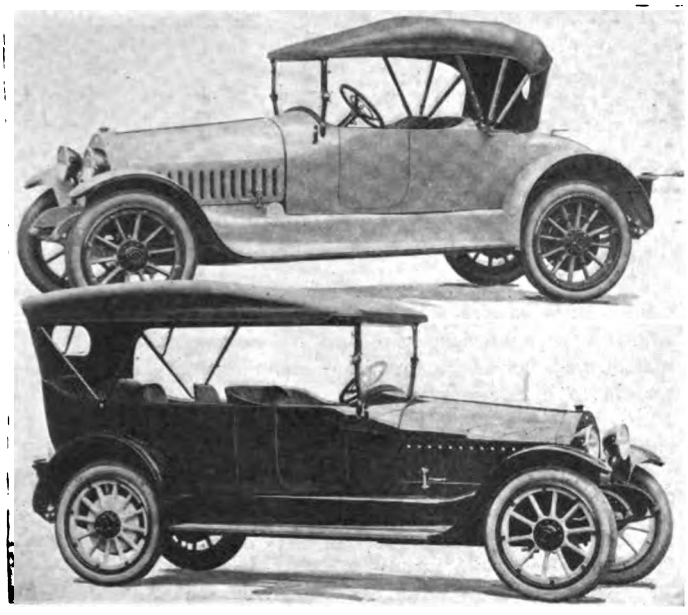
Like the motor the gearbox is attached at three points, two at the rear and one in front. Between gearbox and motor is a universal coupling that allows for any small disalignment that may arise through frame weave, and the splined shaft that carries the sliding gears is very large and stiff.

As can be seen in the chassis view the clutch and brake pedals are carried on a shaft secured to the same cross frame member that supports the front end of the gearbox, while the gear shift and emergency brake levers are mounted centrally upon the gearset. Very particular care is taken in supporting the gear lever as can be seen, the long bearing on either end of the cross shaft insuring that the lever shall always move across the strikers without the least hint of sticking. In practice it is to be doubted whether there are any cars which have an easier handling gearshift and certainly very few indeed have one that is even nearly as good.

Drives Through Springs

Drive from the spiral bevel rear axle is taken through the springs, but the torque is supported by a substantial pressed steel member. It should be noticed that the intermediate brake gear is carried on a cross rail of the frame located at the place where the front end rear spring hangers are attached, this serving greatly to strengthen the rigidity of the drive.

As said before the above dissertation on points of design only touches upon a few new things. The dimensions of the motor remain 4.25 by 5.5 in. bore and stroke, 468 cubic in.,



Above—Marmon 41—Three passenger club roadster. Below—Marmon 41—Seven passenger touring model

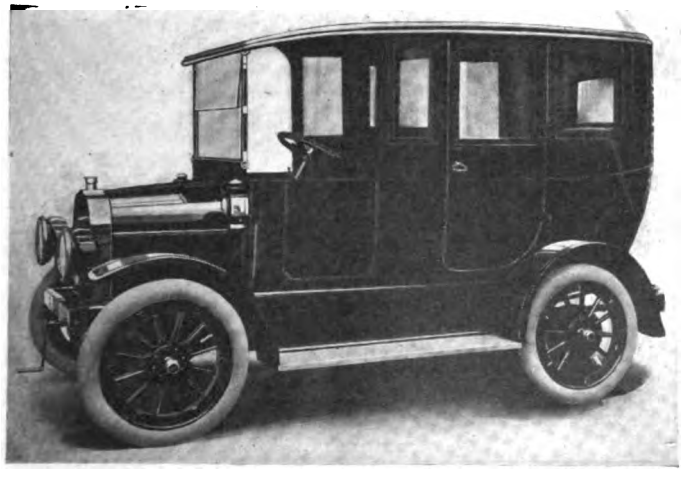
the wheelbase is still 132.5 in. As last year the starting and lighting system is all Bosch with a Willard storage battery and a Bosch magneto is used for ignition. Tires are Goodrich Silvertown 36 by 4.5 all round with one spare rim in the equipment and the price is $3250 for all models except the seven passenger touring car, which costs $3350. There are five models in all, speedster, roadster, four, five and seven-passenger touring cars.

Gear ratios are proportioned to the work the car is expected to do being 3.06 to 1 for the speedster, 3.5 to 1 for the roadster and four-passenger and 3.77 to 1 for the two larger touring cars.

Body Styles

This year a few special three-seated bodies will be made of the clover-leaf pattern where the middle passenger sits between and slightly behind the driver and his companion; one of these was nearing completion on the occasion of a recent visit to the plant and is a smart looking and most comfortable type.

As to the touring bodies these are now aluminum instead of steel so being a little less in weight, and much care has been given to their detail finish. The upholstery ends flush with the body sides and are secured by an internal bead so that the leather is invisible externally, giving a sharp outline to the body. Really the easiest way to describe the body changes is to say that the upholstery and fittings have been gone over with a microscope and every little thing which marred appearance has been removed or altered. There is the same space, the same comfort, the same quality of material, but the new body looks pleasing from every aspect instead of better some ways than others.



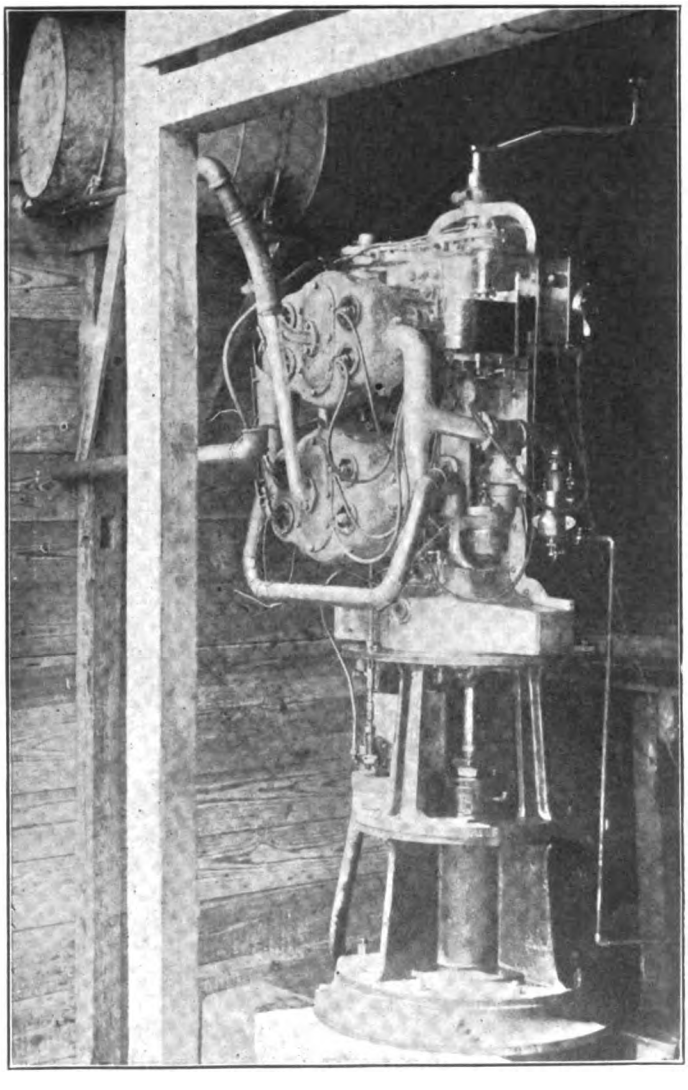
Taxicab recently brought out by Touraine Co., Philadelphia

Wisconsin Motor Operates on End

An interesting example of what can be done with an automobile engine is illustrated herewith. This is a stock model A 4.75 by 5.5 Wisconsin motor, model U, mounted so that the crankshaft is vertical instead of horizontal. The shaft is directly connected to a centrifugal pump and is delivering 750 gallons of water per minute for 10 hours a day.

The biggest difficulty, of course, to overcome in this installation was the proper oiling. In its natural position, the motor has its oil reservoir in the bottom of the crankcase, but in this instance a separate oil tank is placed under the engine and the oil pump connected to the bottom end of the reservoir. From here the oil is pumped directly to the main bearings and then forced through a hollow crankshaft to the connecting-rod bearings. The oil is forced out of the connecting-rod bearings and thrown to the cylinders and other motor parts, then draining back to the reservoir through a strainer.

A feature is the arrangement which has been made to crank the motor. It will be noted there is a platform erected behind it and a long cranking handle placed within reach. The cooling water is in the tank shown above the engine.



Vertical automobile motor made horizontal for stationary work

Bostonian Argues for Resiliency as the Measure of Tire Efficiency

Introduction and Commentary by M. C. K.

NOBODY doubts that resiliency has so far been found to be one of the properties in a tire which is intimately associated with the possibility for getting satisfactory work from the vehicle to which the tire is fitted, and this intimate association with desirable ends has tricked many persons into accepting the measure of resiliency in a tire as the measure of its efficiency, to the effect of encouraging the idea that increased efficiency can surely be obtained if tire makers succeed in increasing the resiliency. A premium is thereby offered for a stronger rebounding capacity in tires, and the search for improved tire materials is artificially limited to those in which resiliency and pliancy go together in the same close union as in rubber and air, the close union of the properties in these materials being in fact the main prop for the fallacious and restrictive axiom by which one of these properties is selected as a measure of tire virtue.

Theory's Practical Sting

Considerable trade importance is connected with the axiom when it is introduced in the specifications for tire supplies in the form of a demand that the tires shall measure as high as possible by a resilio-meter test, thereby placing those tires under a trade ban whose makers aim for improvement through efforts going in a different direction and offering perhaps better chances for ultimate perfection of tires and for a better adjustment of tires to the spring suspension and to loads and speeds. When it is said that resiliency is becoming accepted among electric truck builders as a measure of tire quality, it may be worth noting that a portion of the weight of electric motors is usually suspended upon the wheel axle and that therefore a spring action from the tires may be more needed for this class of vehicles than for trucks and omnibuses in which the unsprung weight is smaller or more robust, and also that the springs of electric trucks are usually made according to the formula which reduces the first cost of the springs to a minimum, namely short, stiff and of small range. While it is not certain that the most resilient tires must necessarily serve best to offset the shortcomings of such springing—for which a great deal can be said at the present stage of spring suspension practice—it is probably true that auxiliary spring qualities are at present most readily found in tires in which the resiliency is as pronounced as possible. It is when the alleged axiom is accepted as having a universal validity governing for all efforts for tire improvement that the need of a sharp distinction makes itself felt.

One Conclusive Exception

Railroads prove conclusively that tire improvement does not tend in the direction of increased resilience when roads are radically improved, and it is almost equally obvious that the shortest road to tire efficiency (in the case of solid tires which notoriously do not allow the road inequalities to sink into them in any degree at all comparable to the action of air tires in this respect) may not be found through an increase of either their pliancy or their resiliency, but very probably through increasing their durability while at the same time enlarging and improving the action of the spring suspension with which the tire co-operates. The universal validity of the alleged axiom is thus disproved in advance by a cursory and untechnical examination of the facts. The hold it has gained in wide circles is so much more remarkable, and the following communication offers an argument in its favor which may be of general interest, although the writer is unable to discover any points or chain of reasoning in it which have not already been met in previous articles on the subject.

Editor THE AUTOMOBILE:—After reading with considerable interest M. C. K.'s comments in the June 10 number of THE AUTOMOBILE on Mr. Duryea's letter of May 21, 1915, I am wondering if many other readers of your popular magazine are not asking, like myself, "Which man is right?"

I would, therefore, like to present a somewhat different analysis of the factors affecting the power efficiency of tires, hoping that it may serve to "clear the air," so to speak, and perhaps bring about a solution of the problem which will be satisfactory to both parties.

In the first place, it may be taken for granted that the maximum power efficiency will be obtained when the sum total of the losses, of whatever nature, are a minimum; and it only remains for us to determine what combination of qualities tend to produce this result without sacrificing any of the the necessary functions which it is intended that good tires should possess.

I agree with M. C. K., when it comes to formulating these rules from the results of certain road tests, that it is not sufficient to take one set of conditions and assume that your conclusions will apply equally well to all other conditions. Nevertheless, I maintain that there are certain underlying principles which will always govern the results and cannot be disregarded by those who seek to explain through "logic" such every-day phenomena as riding qualities, efficiency, etc.

It seems advisable at this point to define the terms commonly used to describe the properties of elastic bodies,—namely, flexibility and resiliency—so as to avoid any possible confusion in the reader's mind, due to his having a different conception of these terms from that of the writer's.

FLEXIBILITY

Briefly stated, flexibility signifies the degree of pliancy, and should only be used to denote the ratio between the amount of deflection or compression and the force producing it, subject to the following conditions: That the elastic limit is not exceeded. That the forces acting are at rest. That the spring-action of the body is undamped either by external or internal friction.

We may represent this property by the following equation:

$$f = \frac{D}{L};$$

where f = the flexibility,
D = the deflection,
and L = the load applied.

In measuring the flexibility of a tire we should be very careful to eliminate the effect of molecular friction; otherwise the results of different observations will not check. We should also specify the load applied, because f varies with the load and is not constant as in the case of a metallic spring.

To get a true idea of the comparative flexibility of different tires we should plot a curve, using for abscissae the load applied, and for ordinates the deflection. In the pneumatic tire we should remember that there is a marked distinction between the flexibility of the tire wall and the flexibility of the tire as a whole when inflated; and we should always make clear which is meant.

We should also distinguish the difference between "flexibility," and "resistance to flexion," because friction affects the latter but not the former, and consequently may produce a marked difference in the behavior of the tire.

RESILIENCY

Resiliency expresses ordinarily the "liveliness" of an elastic body, and is represented by the ratio of the *energy* recovered

in the rebound to the *energy* in the blow. It depends entirely upon the extent to which the action of compression and the subsequent expansion is damped by friction. It is in itself an expression of efficiency, or "output-over-input"; and should not be confused with "flexibility" which is based on the action of a *frictionless* spring or other elastic body.

If one tire is more resilient than another it does not mean necessarily that it is less flexible as a whole, but it may be due to superior construction which reduces the internal molecular friction, notwithstanding the fact that the same tire may be made more resilient as a whole by using a higher degree of inflation, which at the same time, of course, reduces its flexibility.

EFFECT OF RESILIENCY ON EFFICIENCY

In determining the effect which resiliency has upon efficiency it is quite possible to answer the question without going into a lengthy explanation of the reaction of the tire upon the road surface, which is more or less involved and seems to have led some thinkers away from the solution of the problem rather than toward it.

In view of the fact that the tire is an elastic body it must be flexed to a certain degree by the load which it is obliged to carry. Furthermore, since it *is* elastic, it must recover its original shape when the load is removed, otherwise the tire would grow thinner and thinner with each revolution of the wheel like a batch of dough under the action of the much abused rolling-pin. During each cycle of compression and expansion a certain amount of energy is consumed in overcoming the molecular friction in the wall or other solid elastic parts of the tire. This energy is entirely wasted and appears only in the form of heat, which under certain conditions may become very intense. Obviously the energy so consumed detracts just that much from the propulsion of the vehicle; and, in the proportion this loss is reduced, the efficiency will be increased. There can be no other result.

As far as the bouncing of the wheels on the road is concerned, we have to consider other factors besides the resiliency of the tires, because that is only one among the many involved, and I doubt if it can be proved that bouncing in itself retards the vehicle excepting as it allows the driving wheels to slip on the road if they are thrown upward with sufficient force.

Fortunately there are other ways of preventing the wheels from bouncing than by reducing the resiliency of the tires, which it has been demonstrated greatly reduces their efficiency. Increasing their flexibility as a whole is one way, and for the others we may turn to the designers of the springs, running-gear, and shock-absorbers to provide.

CONCLUSION

The task of the tire builder, as I see it, is to build a tire which will properly relieve the unsprung portions of the car from the shocks due to small irregularities in the road surface; and at the same time, if the tire is to have the maximum efficiency, which means that the internal losses shall be a minimum, it must be resilient whatever its flexibility.

Boston, June 21, 1915. RUSSELL HASTINGS.

P. S.—If I have not made myself quite clear on any points, I should appreciate having the privilege of explaining them before you publish the letter (if you see fit to do so) rather than afterwards.—R. H.

Single Criterion Usually False

In view of the postscript the writer refrains from all detailed comment upon Mr. Hastings' presentation of the subject, so much more willingly as he knows of no single property which can be accepted as a criterion of tire efficiency in the place of resiliency but inclines to the belief that tire improvement must go hand in hand with the improvement of springs, wheels and roads, must vary in its means with the vehicle speed and maximum load and, on the whole, is as closely interwoven and organically connected with other motor vehicle improvements as, for example, the type of the motor. The greatest fuel efficiency is no doubt obtained from a motor of very high piston speed, yet no one could contemplate establishing motor speed as a measure of motor merit. It would be an industrial calamity if anybody succeeded in doing so.

When the subject in hand is narrowed down to a question of the desirable properties in solid tires, the writer would formulate the task of the tire maker along lines somewhat different from those followed by Mr. Hastings. With no restricting theories to work for, traction qualities, noiselessness and durability become the leading requisites, with economy in cost of production closely following and with reform efforts directed mostly toward inducing vehicle manufacturers to adopt such wheel and tire dimensions and such spring systems that the effect of tire material upon power efficiency of the vehicle will be reduced to a minimum.

By working for large dimensions, the demand for power efficiency can be met in a rational manner to a considerable degree and whatever may be further done for the same purpose through improvement of the tire material may then be undertaken under small stress. The most prominent considerations which arise in this connection seem to the writer to be the following.

Requisites for Power Efficiency

Power efficiency is determined mainly on smooth roads, in so far as a tire which is not efficient on smooth roads will have a low total efficiency—the smooth-road action of a tire being the fundamental one to which all other action is only spasmodically added—and it is known that the smoother the road the more rigid the tire should be to have power efficiency. Neither pliancy nor resilience is here wanted. Pliancy is wanted however for absorbing shocks and giving vehicle springs time to start their action, as well as for noiselessness. Resilience, though a prime requisite in stationary (not rotating) vehicle springs, is wanted in tires only to restore the deformed tire to its round shape and only in the degree required for that purpose. All other usefulness of resilience in tires, to increase power efficiency, is fictitious. The power wasted in flexions is not restored for use in propulsion by a resiliency which restores a tire to its shape with such promptness as to cause a rebounding of the vehicle. Resilience in tires only keeps the pliancy of the tires operative.

In accordance herewith, the requisites for producing power efficiency are rigidity on smooth roads and pliancy for shocks plus a modicum of resilience to maintain the shape of the tire. These requisites are plainly contradictory and have to be reconciled by compromise, but resilience plays a subordinate part among them and cannot be the leading aim.

A Question of Materials

Necessity is something else. It may be a necessity to use highly resilient materials in order to obtain the pliancy and flexibility that are wanted. The use of compressed air in air tires is an important example. It is wonderfully pliant but also so resilient that it reacts at once with full force against any deformation. For its use in tires its resilience in this degree is unfortunate, as it takes effect in bouncing the wheel back from the very same obstacle which causes a deformation, unless the vehicle speed is high. Now, the question for the maker of solid tires may be said to be just this—where power efficiency to be obtained through the choice of materials is concerned—of finding a material which will act at all speeds as an air tire acts at vehicle speeds so high that the excessive resiliency of air does no harm, getting no chance for rebound against the ground.

It is certain that a highly resilient material is not what is intrinsically wanted, as it has the drawback of causing immediate rebound. But whether the high resilience can be sidetracked in practice is another question. To solve it by assuming that maximum resilience is a virtue is to make a virtue out of something which has not even been proved to be a necessity.

Dimensions Reconcile Conflict

On the other hand it is easily demonstrated that large dimensions offer one safe method for reconciling the conflicting demands in some degree, giving comparative rigidity for smooth roads in conjunction with an acceptable degree

of flexibility for absorbing shocks resulting from impacts with relatively small objects.

Specific Pressures Most Important

The larger the wheel and tire, the smaller the flexion which will produce a considerable contact area for the support of the load and therefore the greater the flexibility which can be allowed in the material to help in absorbing the road obstacle and in tempering the shock.

It may perhaps be objected that the work involved in the flexion is always determined by the load and should be the same whether the flexion is large or small, but, as the work done also depends on the distance through which the load must act in accomplishing the flexion, it is susceptible of proof that a flexion which may be considered as dropping the load level one-quarter inch (in the case of the large wheel and tire) consumes less power than a flexion caused by the same load but involving a drop of the load level amounting to one full inch. This is perhaps generally admitted and the demonstration need therefore not be made explicit.

Road Dust in Cylinders and Bearings—Effects and Remedy

CARBON deposits, it is widely admitted, are more troublesome the higher the piston speed of the motor. Clogging of carbureter nozzles, it has been whispered from abroad, occurs with some frequency in those excellent carbureters in which a little air is admitted to the interior of the jet. Chemical analysis of the carbon deposit in any motor, it has been established in Germany, reveals a proportion of silica varying from 2 to 8 per cent, besides some other impurities which can scarcely be traced to any other origin than road dust. These observations singly and jointly call attention to a feature in construction and operation which seems to have been neglected and which may yet have a considerable influence on the adjustment and durability of motor bearings, on compression, on knocking, on premature ignition and on backfiring. The feature referred to relates to the lack of provisions for keeping road dust out of the fuel charge and thereby out of the cylinders.

Assuming that a certain amount of dust is in suspension in the air under the motor hood but is in the act of settling by gravitation owing to the slowing up of the air current which takes place after it has passed through the fan, it stands to reason that more of this dust will be drawn through the carbureter if the suction is strong than if it is mild, and that the motor with high piston speed therefore will inhale more dust per cubic inch of air than the slower motor. As its combustion chamber is also smaller and more compact, having a relatively smaller wall area, and as flame propagation is more rapid in this type of motor, it is not difficult to believe that the necessity for frequent removal of the carbon deposit from such motors has something to do with the amount of dust inhaled and is not merely an expression for the related fact that any coating interferes more with operation in a high-speed motor than in a slower one on account of the greater need of good cooling and of keeping the volume of the combustion chamber from being reduced. In the majority of informal statements on the subject it is claimed that the carbon deposit is thicker as well as more troublesome in the high-speed motor, and this would be almost conclusive with regard to the source of the deposits if the obtainable data were explicit in giving dates and mileage. If everybody who has kept records bearing on the subject, including records of his motor repairs, would contribute a copy of them to the fund of public information, the question could probably be decisively answered even if each contribution were not very complete.

Why Air Is Not Filtered

The principal objection to filtering the air which enters the carbureter is perhaps the same which militates against the use of backfiring screens, namely that any arrangement of this nature tends to obstruct the flow of air and thereby reduces the volumetric efficiency, counteracting the good effects of large channels and valves, unless the whole air conduit is considerably increased in area—and this would mean an increase of some of the carbureter dimensions. While the points in carbureter design which are involved are not the same for filters as for backfiring screens, which are above the jet, they are practically the same as for the use of screens in aviation motors to prevent a carbureter fire from spreading to other parts. It is perhaps worth while inquiring if something may not be done to reduce the dust intake without interference with carbureter design and dimensions.

Strong Hint from Radiator Practice

A discussion at one of the S. A. E. meetings throws some light on this possibility, which consists in filtering the air before it enters the hood. A paper on radiators by Howard Greer, Jr., of the McCord company, gave occasion for the remarks which bear on the subject, and while these did not refer to the dust question at all but solely to cooling, especially fan and radiator efficiency, they seemed to establish the desirability of diffusing the air current passing through the radiator as much as possible—by whatever suitable means this may be accomplished—and thereby suggested that some kind of an air filter might be used for this purpose, not only serving to exclude the dust but also regulating the cooling effects of fan, radiator and vehicle speed.

Some of these remarks are herewith quoted. "After you drive the air fan beyond a certain speed you get air at anywhere from 950 to 1150 ft. per min.; if you get it at a higher rate than that you shoot a core of cold air right through the center of the air passage [meaning each of the many air passages in a radiator]; the skin air is not disturbed and you do not take the heat out [of the adjacent water tube] in proportion to the speed at which you are driving air through."

With regard to the factors which make dust tend to settle, like the impurities of river water in a settling basin, the following is of interest: "Air is pulled through the radiator and jammed against the motor, starter, water manifold, exhaust manifold, wires and all kinds of things." And, speaking about blowing some sparks—which may be considered incandescent specks of dust—and seeing what happens to them: "I have seen a spark put in from the front of the car go over and actually circle around the manifold and then dive down to the bottom and then come out. . . . The space is not only restricted but baffled; these restricted corners cause all kinds of swirls, and the velocity of the air going out is much less than of that coming in, because it creeps out the sides and front and all kinds of places instead of going out some definite passage." Also: "In the conventional construction you take a highly refined piece of mech-

Splitdorf Announces Twelve-Cylinder Magneto

Dixie Models Now Include Eights and Twelves—Eight Operates at Engine Speed

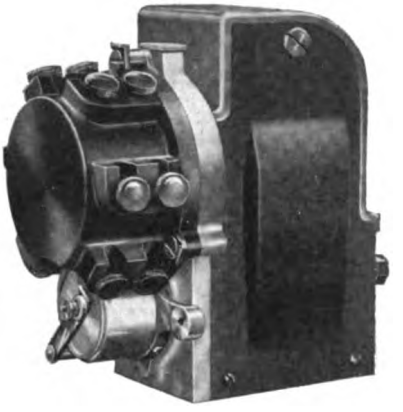

Fig. 1—The latest Dixie magneto has its twelve terminals arranged on a compound distributer

BY adding a 12-cylinder model to its line of Dixie magnetos the Splitdorf Co. is able to furnish ignition for any automobile engine on the market. This new magneto operates on the same principle as the other Dixie models, having stationary windings and no armature in the ordinary sense.

The Mason principle on which the Dixie magnetos operate is a radical departure from ordinary magneto practice, and possesses many features of great interest. In the first place the rotating shaft passes through the magnet poles instead of between them and instead of carrying an armature on which the windings are placed this shaft carries two solid polar extensions separated by a non-magnetic distance piece. Surrounding these revolving pole pieces is a light laminated field structure consisting of two pole pieces *F* and *G*, Fig. 2, and a straight core on top. This core carries both primary and secondary windings. The principle of operation is that of sending magnetic lines alternately in opposite directions through the field structure. It will be seen that the pole extensions *S* and *N* are simply a means of carrying the magnetic lines from the main magnet to the laminated field structure and that they do not change their polarity. In the four- and six-cylinder models each polar extension embraces about 90 degrees of the tunnel.

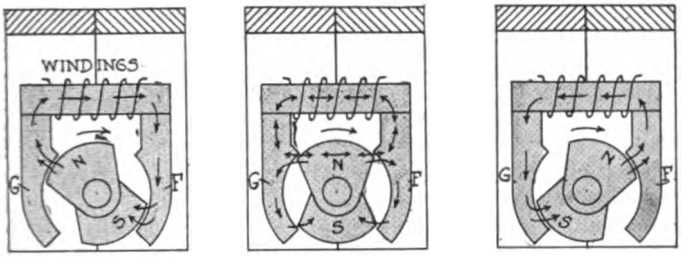

Fig. 2—Principle of operation of the Dixie magneto showing the stationary windings and magnetic field

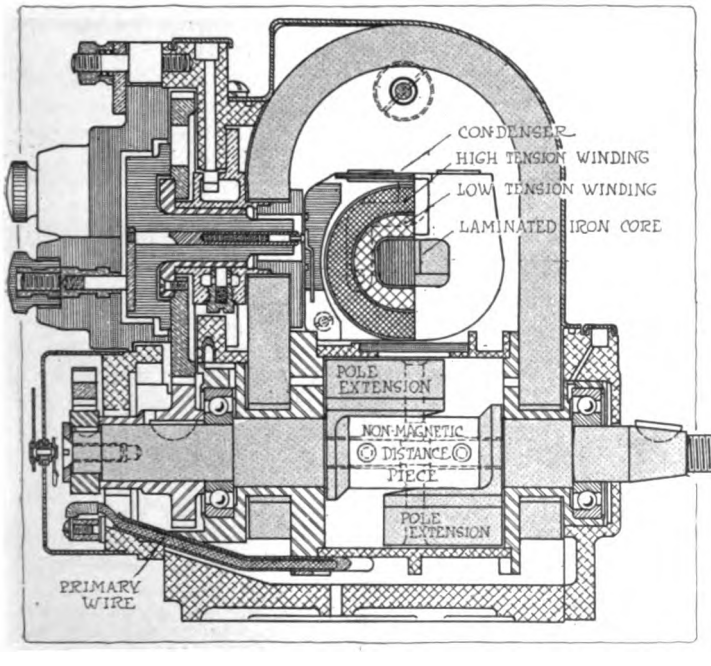

Fig. 3—Half-size section to scale of the 4-cylinder Dixie showing location of stationary windings and rotating pole extensions

Path of the Flux

When the pole *N* is adjacent to *G*, Fig. 2, left, the magnetic flux flows in the direction of the arrows through the core of the windings from left to right. Continuing the rotation of the poles until they occupy a vertical position it will be seen that the field of the magnet is shorted through the pole pieces, cutting out the magnetic flux entirely from the core. Passing this point in rotation the pole extension *N* then comes into a position adjacent to *F*, causing the magnetic lines to flow once more through the core, but this time in the opposite direction, that is, from right to left. This reversal of direction of the magnetic flux is of course a necessary feature in any magneto and is the means of inducing the current in the windings.

In order to render this reversal easy and complete the path for the magnetic lines is made up of thin iron laminations such as are used also in the construction of the armature in the ordinary magneto. The Splitdorf Co., however, make the claim for the Dixie construction that a point of great efficiency is obtained since the bulk of iron in the stationary field structure is so small, its size being governed entirely by magnetic requirements.

The windings are remarkably small, being wound on a core of only 0.75 by 0.5 in., Fig. 3. The core is held in place by two screws passing through slots in the projecting ends. One end of each of the two windings is earthed. The open end of the high tension winding terminates in a contact plate *P*, Fig. 6, embedded in a rubber block at the side of the windings. The open end of the primary winding passes through a brass tube which leads to the base of the magneto and so to the contact breaker, Fig. 3. In dismantling, this wire is the only electrical connection to be loosened.

The Rocking Field

One of the most important features of the magneto is that the whole of the laminated pole structure including the windings can be rocked through several degrees. This rocking is accomplished by turning the timer arm of the circuit breaker in the ordinary way to advance or retard the spark. By means of this positive connection between the field and the circuit breaker it is possible to arrange the instrument to produce the sparks either advanced or retarded at the critical moment when the most magnetic lines are being cut. Hence the magneto has no one point in its spark position when the intensity of the spark is maximum or minimum; it is uniform all the time.

The distributer on the four- and six-cylinder models, Fig. 6, consists of an insulating block with a short spindle at one

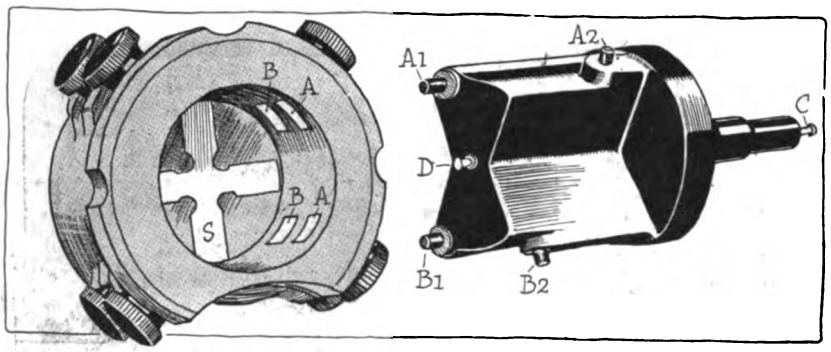

Fig. 4—Compound distributer box and block on the eight-cylinder Dixie magneto. The distributer on the twelve is the same except that the contact piece S which transfers the high tension current to the terminal plates through the brushes in the block is six-pointed to supply the twelve terminals

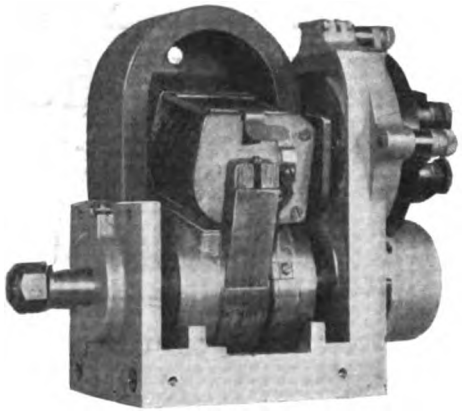

Fig. 5—Interior view of four-cylinder Dixie with cover and one of the magnets removed to show the windings and rocking field

end of which is a spring brush bearing on the contact quadrant *P* on the windings. The high-tension current passes from this point to a radial arm on the distributer face and so to the outer terminals of the instrument. A good feature is the shortness of the path for the current from the windings to the terminals. A safety spark gap is included in the high-tension circuit at the base of the windings, and the condenser is located on top.

In the circuit breaker, Fig. 6, it will be seen that nothing revolves except the cam attached to the shaft. By this construction it is possible to adjust the contact points while running as the contact bases are stationary. The grounding terminal is insulated on the end of the spring clip which holds the breaker cover in position and as it bears on the center of the cover the ground wire is also stationary while moving the timer arm.

The four- and six-cylinder instruments are identical in every respect except the distributer and timing gears. In the eight- and twelve-cylinder models the shape of the rocking field and also the polar extensions are changed so that four sparks can be produced in each revolution. Fig. 6, right, shows the shape of the laminated pole pieces which embrace only 50 deg. each of the upper half of the tunnel, instead of 90 deg. In order to obtain the requisite number of magnetic reversals with these pole faces the main polar extensions are in the form of a cross, two ends being of *N* polarity and two of *S*.

The New Compound Distributer

As it is practically impossible to obtain more than six contacts in a flat distributer disk of ordinary construction without a great risk of short-circuits caused by dangerously small electrical hazard distances a particularly ingenious compound distributer, Fig. 4, has been designed for the eights and twelves in which the terminals are not arranged in one plane as in the four- and six-cylinder models but in two parallel planes. In the compound distributer block on the eight-cylinder instrument the high-tension current is led through the center of the block from the brush *C* in contact with the windings to the brush *D* which bears on the center of the cruciform contact plate *S* embedded in the distributer box. This plate has no connections with any terminals but is a means of conducting the current in turn to the eight terminals as follows: In operation the plate *S* becomes "live" by contact with the brush *D* as before explained. Rotating over the ends of *S* are the two brushes *A1* and *B1* connected respectively to two similar brushes *A2* and *B2* in the side of the block. The path of the latter brush *B2* includes the four contact pieces *B* connected to the four of the terminals while the other brush *A2* rotates in the path of the terminal plates *A* connected to the remaining four terminals. Now, since the two brushes *A1* and *B1* are arranged 135 deg. apart it follows that eight sparks will be distributed to their respective terminals in one revolution of the distributer block in equal divisions of time. The timer gear is in the ratio of 2 to 1 so that this magneto runs at engine speed, an unusual feature of an eight-cylinder magneto. On the twelve the distributer gear ratio is 3 to 1 requiring a speed one-and-one-half times the engine speed.

12 Distributer Similar to 8

The distributer for the twelves is identical in every respect except that the contact star at the base of the box is six-pointed instead of four to supply the twelve terminals which are arranged in two layers as shown in the external view, Fig. 1. By the use of the compound distributer block on the eights and twelves as many as 285 sparks of high intensity can be obtained per second. Owing to this high speed of spark production a double contact breaker having two breaker arms and contact points is used on the twelves.

Constructionally the Dixie magnetos are up to the present high standard of practice. The shaft runs on ball bearings, tightly fitting brass side covers inclose the magnets and the

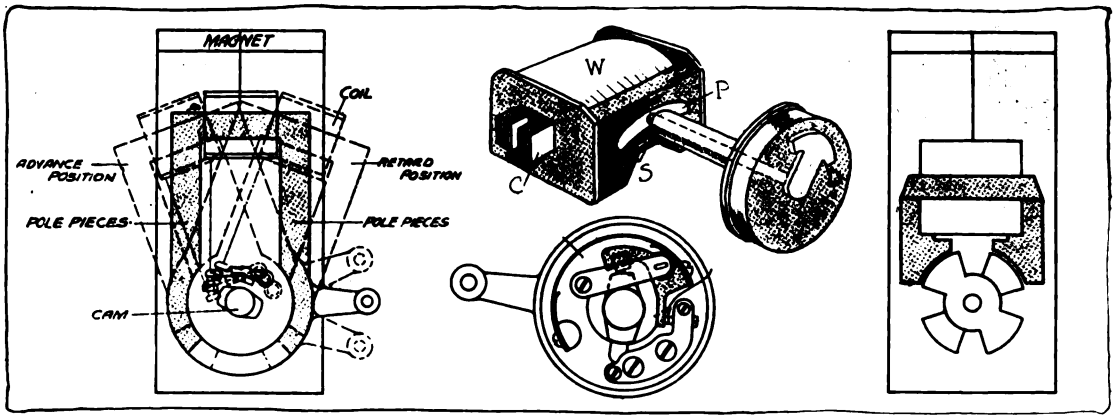

Fig. 6—Left, showing how the laminated field with its windings rocks inside the magnets simultaneously with the circuit breaker. Center, the windings and distributer block of the four-cylinder model, and below, the distributer with stationary contact points. Right, the laminated field on the eight and twelve-cylinder magnetos in relation to the rotating pole extensions

whole instrument can be dismantled with no other tool than a screwdriver. The magnet itself is in two parts and fits into place without bolting, having semi-circular notches which embrace the shaft bearing. Great accuracy has been used in the manufacture of the rotating pole extensions, the clearance between the ends and the stationary poles being brought down to the workable minimum. An interesting point in connection with the operation of these pole extensions is that end thrust is neutralized by the equal magnetic pull on both ends of the rotor. The compactness of the magnets can be realized from the dimensions which except in the height are practically identical in all models. The common width is 4.125 inches and the total length 8.375 inches. On the twelve the height of the magnet is 7.5 inches being one inch more than the others so as to provide a stronger magnetic field.

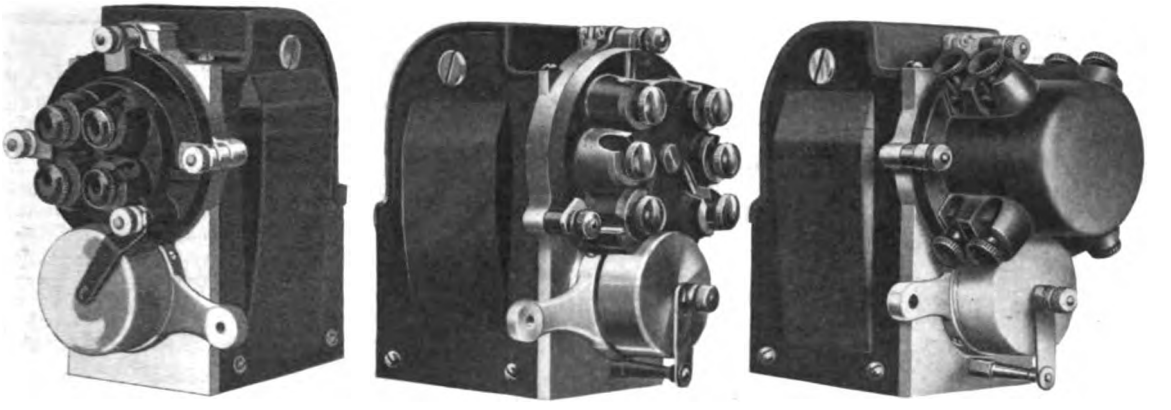

Fig. 7—Models 40, 60 and 80 Dixie magnetos for four- six- and eight-cylinder engines

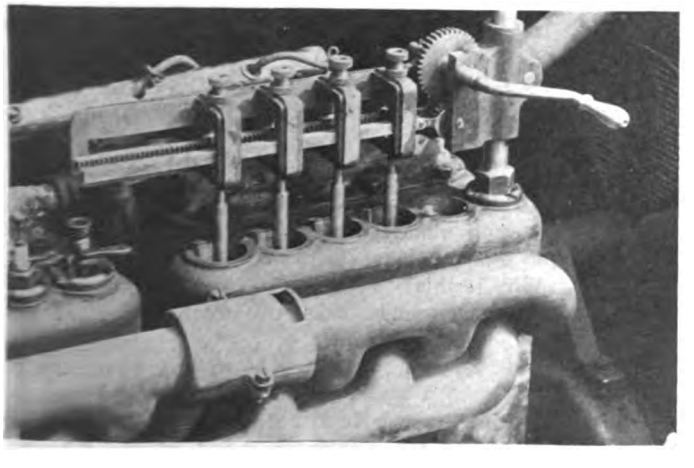
The four automobile models are designated 40, 60, 80 and 120 for four-, six-, eight- and twelve-cylinder engines.

Multiple Valve Grinder

A simple valve grinder by which four valves can be ground at one time and which device can be rigidly attached to any motor in a car, has been brought out by Knepper and Wright, Detroit, Mich. Turning the handle at the right is all that has to be done in grinding the valves. This imparts a back-and-forward movement to the horizontal rack, which in turn gives a short back-and-forward movement to the four screw drivers which engage in the slots in the valves. Additional pressure on any valve can be had by the knurled adjusting screw on the top. As shown the device is attached to a spark plug hole but this is not the only method, for special devices are made to suit different types of engines and those with detachable cylinder heads can be dealt with just as readily as the type illustrated.

Naturally this tool is intended more for use in garages and repair shops than by the private car owner, but its wide range of adjustability and the consequent ease of attachment to almost any engine ought to enable valve grinding to be performed at a slightly cheaper rate; a distinct advantage to the owner in these days of many valves.

One of the great advantages of a tool of this kind is that it can be relied upon to give an even pressure at all times. Sometimes with the hand method the pressure upon the bearing seat will be much greater than at others and an even seat for the valve is not gained as quickly as with the mechanical method.



Knepper multiple valve grinder ready for action

Belgian Armored Cars Most Efficient

(*Continued from page* 10)

section cans in which reserve gasoline is carried, also the special lubricating oil cans, and has special grooves to receive tires. Along the lower portion of the two sides are a series of lockers—six on each side—with a door on the outside. These lockers contain various small parts, stowed away systematically, and as readily accessible as the stock in an automobile store. Each compartment has its own lock, and in addition a catch to prevent the door flying open if the attendant fails to lock it. The store keeper maintains a complete list of the parts in his possession; as each part is given out he records the fact in his storebook and arranges for replacement to be sent to him when a certain minimum has been reached. He thus knows at all times, without going through his lockers, what material he has in stock.

The Armored Cars in Action

An armored car corps in action is a thrilling sight. Suppose, for instance, a village held by the enemy has to be attacked. The cyclists are first sent forward to reconnoiter, draw the enemy's fire, ascertain his strength and the condition of the roads. During this time the cars are concealed in the rear, and the motorcyclists are used for carrying dispatches from the advancing cyclists to the corps commander at the rear. When the attack is decided upon, the corps may be divided into two sections, each one of which has instructions to dash through the village by a different route. On such a dash it is probable that the quick firing guns will have to be employed, although the cannon can be brought into operation immediately if it is needed for attacking a stronghold. A charge through a village is usually made in staggered formation, one car being on the right hand side of the road, the next one 50 yards to the rear on the left hand side, and the third again on the right. Unless the village is scientifically fortified, it is practically impossible for an infantry force to stand before a raid of this nature. Comparatively little use can be made of armored cars in trench warfare, but in an advance or in covering a retreat they are invaluable. In the case of a retreat, for instance, their extreme mobility enables them to hold a position until overwhelming forces are brought up and to get away at the last moment with very little fear of capture. On the other hand, retreating forces of the enemy are most seriously harassed by cars which can dash in, attack and retreat at 40 miles an hour.

The Rostrum

Communications

¶ The editor of the Rostrum is anxious to secure from car users and others, communications dealing with the overcoming of difficulties in making repairs and in the numberless other phases of every-day automobiling. This department is mutual and is a common ground upon which an interchange of ideas and opinions can be made as freely as in the clubroom.

Inquiries

¶ The purpose of the Rostrum department is primarily to aid in the solving of motorists' problems. Readers of THE AUTOMOBILE *are requested to allow our editorial staff aid in the solution of difficulties as they arise and perhaps through this assistance reduce the cost of upkeep of their cars and gain a useful knowledge in the economical phases of the vehicles.*

Carbureter Is Probably Too Small

EDITOR THE AUTOMOBILE:—I have a model 16 Buick equipped with a model L Schebler 1 1-2-in. carbureter which is causing me considerable trouble. When the engine is running slowly, it works fairly well. I can open the throttle quickly and the engine immediately picks up and does not skip, but as soon as I start up a hill it begins to skip even with a half throttle and when it reaches the speed of 38 miles per hour, it will skip, spit back through the carbureter and fire in the muffler. I have had the dials set at all points, sometimes adjusting it so it will work good for 10 or twenty miles, but it will be almost impossible to do anything with it. I think the float has been moved, as it is 7-8 in. from the top of the bowl. What suggestions can you offer on this? C. A. B.

New York City.

—It would seem that you have changed the carbureter on your model 16 Buick from the original Schebler D, which was used for standard equipment, and put on a 1 1-2-in. size model L. If this is the case, you have too large a carbureter on your car. The proper size for you to use on model 16 Buick would be 1 1-4 in., that is, the 1 1-4-in. model L.

The carbureter being too large would require a large amount of heat to keep it from loading up when the motor is running slowly. This, as stated, is due to the large size of the carbureter. The correct level of the cork float should be 1 1-16 in. from the top of the bowl when the float valve is closed.

Relative to the motor missing at a speed of 38 miles per hour, it would be very likely that this is due to ignition trouble. The breaker is not working properly perhaps at that speed.

Chains Probably Not at Fault

Editor THE AUTOMOBILE:—Please tell me if the slack can be taken out of the chains which run the cam and magneto shaft on the Paige 1914 model 36.

2. What remedy can you suggest for a rattle which occurs when the clutch is disengaged? It is of the multiple-disk type with cork inserts. K. M.

Eunice, La.

—While the drive chains used on the model 36 Paige motor will stretch to some extent, they will not do so sufficiently to cause any trouble while the motor is running smoothly, as there would be a steady pull on the chain and hence no possibility of their causing a slap.

If trouble develops with the pump drive chain, it would be more apt to be caused by the pumpshaft bushing becoming worn, which would allow extra slack in this chain, and the remedy therefore would be in the installation of a new bushing. If the trouble is in the generator drive chain there is no way by which this can be adjusted other than by removing the bolts which fasten the generator to its supporting bracket, elongating the hole and moving the generator out slightly. If this were done care must be used in resetting the generator so as to get same so that the chain will be properly aligned.

The chain driving the camshaft is a shorter and much heavier chain than the other two and, in fact, is much heavier than is necessary for the work which it has to do and should not ever cause any trouble.

2. The clutch rattle may possibly be caused by the prongs on the shifting bar not being of equal distance away from the thrust bearing. This can be determined by inserting a feeler gauge between the prongs and the bearing and if one is found to be closer than the other, the distance should be equalized by bending back the one which is closer.

There is a tendency for a rattle to occur in this type of clutch when it is disengaged, especially when coasting on a down-grade or when driving over a rough spot, but this can be overcome by bringing the shifting lever into neutral position and allowing the clutch to remain engaged, especially while coasting down a grade.

Water Boils at Higher Speeds

Editor THE AUTOMOBILE:—The following question has puzzled every one whom I have asked, and I will appreciate a word from you relative to this question.

I have a Buick roadster, model 30, which travels well up to a speed of 20 miles per hour, but when the speed is increased, the water boils so fast that the radiator is soon emptied and consequently I have the usual trouble which accompanies a heated engine. The pump is in good shape, new heavy hoses all around. The radiator was opened up and all the tubes were free and also the tanks are in good shape. Circulation seems to be good. The cylinders have recently been burned out with oxygen and I am at a loss to know what is causing the trouble. H. B. TREVOR.

Buffalo, N. Y.

—It would seem that your trouble must result from one of two causes: First, an improper setting of the spark, which can be corrected by advancing the magneto, or second, by a collapsing hose connection between the radiator and the water pump, which, at 20 miles per hour or over becomes closed due to the suction of the pump. This latter cause seems to be the most probable and it can be remedied by winding a piece of wire into the shape of a coil spring and inserting it tightly into the tube, thus holding the wall against collapsing under the suction of the pump.

When a Motor Stops Quickly

Editor THE AUTOMOBILE:—Some engines such as the Pierce-Arrow, stop almost immediately after the switch is cut off, while other engines seem to lose their momentum gradually. Why is this?

2—What American-made cars use carbureters of the Claudel type?

3—Would this type of carbureter be of any advantage in connection with such a motor as the Packard 48, Pierce 48, Stevens-Duryea, or Stearns-Knight six?

4—What would be the maximum speed of the following cars geared up and in running trim: Packard 48, Pierce 48,

Stearns-Knight six, Stevens-Duryea and Peerless 48?

5—What is the maximum speed of the Rolls-Royce, Packard 48, Pierce 48, Stearns-Knight six, Peerless 48, Stevens and Simplex 75?

6—Please give specifications of the Packard Twin Six. Also, speed, fuel consumption and weight?

New Haven, Conn. T. B. S. D.

—When the switch is cut off on an engine, it is merely a matter of bringing to rest the moving parts which are no longer propelled by the explosion of the gases in the combustion chamber. Only one influence is probably great enough to be considered as the opposing factor to the movement of the motor, and this is the internal friction. When this has exerted its influence to such an extent that the motor is unable to turn itself over against the compression of the cylinders, it will come to rest. The compression is not an opposing factor unless the momentum is insufficient to carry the motor over top center, because when it is carried over top center the expansion of the compressed air gives up practically all the power which was utilized in compressing it. If the compression is exceptionally heavy, then the speed does not have to be reduced as far as it would if only a light compression were used, before the engine will be unable to turn itself over the dead point. With these considerations, it will be easily seen that a motor with tight bearings, tight piston rings and high compression will come to rest much quicker than one which has the opposite conditions. Of course, a gas-tight motor is more efficient under running conditions than one which is too free.

2—No American cars are regularly equipped with the Claudel carbureter.

3—THE AUTOMOBILE has never carried out any experiments with this carbureter on the cars you mention, and since this is the only way of determining the results, no information can be given you on this matter. It might be possible that the companies referred to have experimented on this carbureter on their respective makes, and would be willing to give you the desired information.

4—You do not mention the gear ratio in questions 4 or 5. Under most advantageous conditions it is difficult to fix a maximum speed for any car as it will vary, even on the same make. Under touring conditions, any of the cars you mention should be able to do 65 miles per hour.

5—Complete specifications of the Packard Twin Six will be found in THE AUTOMOBILE for May 27, 1915, page 933.

Advanced Spark Causes a Pound

Editor THE AUTOMOBILE:—What is it that causes the tapping sound in a motor when the spark is advanced too far, when motor is laboring? Why is it that this happens when a motor is new and the pistons, wristpins and rings are absolutely tight and perfect fitting? Is it a piston slap?

Newark, N. J. L. A. MILLER.

—Very often with the spark advanced too far, the pound given by the motor is simply the impact of the working parts transmitted to the volume of exploding gas in the combustion chamber. This is communicated throughout the motor and the resonant qualities of the metal in the motor permit a pounding effect to ensue. With pistons that are any way loose at the bottom, the reversed power causes a slap as you mentioned, but even without the piston slap the pounding noise would be in evidence. The reason for this jarring is evident from a diagram which explains the opposition of the two forces acting upon the motor during pre-ignition. These are, first, the tangential force on the crankpin and, secondly, the downward thrust of explosion along the connecting rod. Referring to Fig. 1, the tangential force *A* is tending to force the moving parts in the direction of the arrow and the thrust along the connecting rod is tending to act in the direction *EB* at an angle to *EF*, the axis of the cylinder. *CD* is the projection of the horizontal plane through the crankpin. To the right of the same illustration is shown the parallel set of conditions when ignition takes place beyond upper dead center. In the latter case it will be noted that the forces represented by the arrows *A* and *B* or, in other words, the tangential and thrust forces are in the same quadrant as regards the vertical and horizontal planes. They are therefore acting with each other and not against each other as at *A* and *B*.

With the present tendency of putting the piston rings at the top and none at the bottom, there is sometimes a slap caused by the oscillating of the piston about one of the upper rings, brought on due to the reversal of power to pre-ignition. It must be remembered, however, that even with the best fitting motors, a charge pre-ignited will find any place where there is backlash, as the reaction even carries through the timing gears, valve mechanism, etc.

Knock Due to Over-compression

Editor THE AUTOMOBILE:—Would be pleased to have your opinion on the following: A 1913 Ford has been run about 8,000 miles and it has a knock which seems to be in the two front cylinders. It knocks when the car is running on the road or when it is standing still with the motor running. All the bearings have been carefully gone over by two different garagemen but neither could find the trouble. It does not knock any harder when car is climbing a hill than it does when running on the level. When the spark is retarded, the knock can scarcely be heard.

Johnstown, O. W. D. DAVIS.

—Although it is impossible to judge the source of this knock from the particulars which you give in your letter, it would seem very possible that for some reason or other the motor has too much compression. If the cylinders are removed and a fiber gasket fitted between them and the crankcase it is possible that the knock will disappear.

Oil Not Suitable for Two Purposes

Editor THE AUTOMOBILE:—Is there a six-cylinder roadster of standard make that weighs under 2,300 pounds?

2—Is there an underslung roadster made which has the multiple disk clutch running in oil?

3—What is the objection found to transmission gears built in and receiving the same oil as the cylinders? Is there any great objection to this oil as used in crankcase as a lubricant to the transmission gears?

4—What final ratio is considered best on cars with 33 by 4

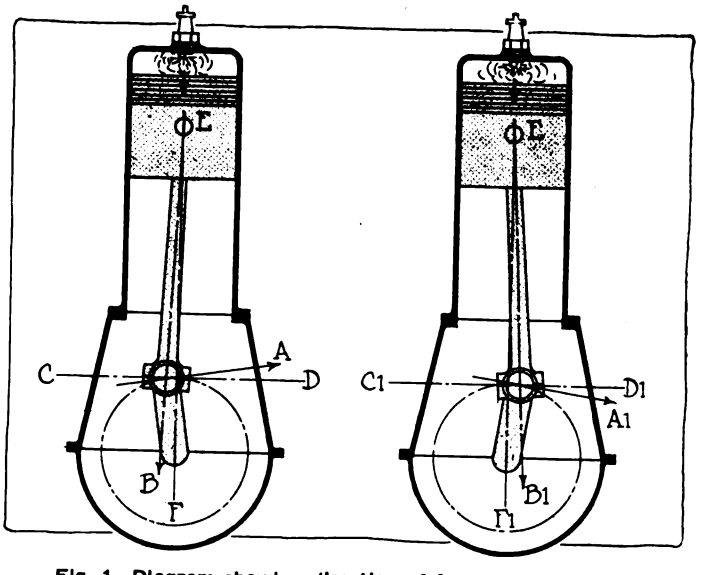


Fig. 1—Diagram showing direction of forces on preignition

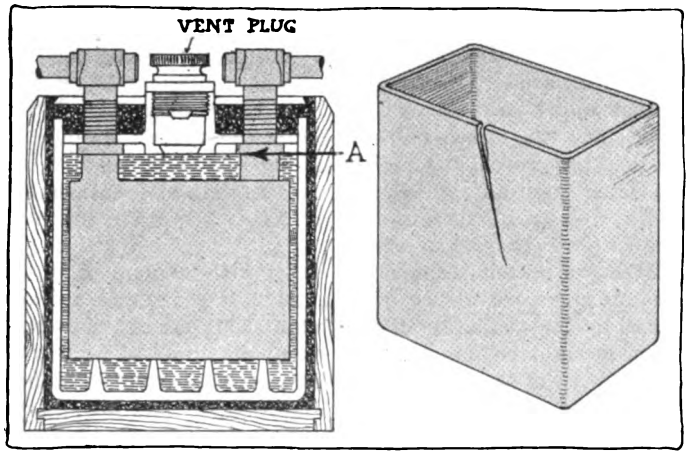

Fig. 2—Section through Willard battery and a cracked jar which sometimes causes a leak. Battery should be filled to A

tires and what speed should be obtained from this ratio?

5—Can the low speed of an ordinary gearset be changed to a lower ratio without changing the two higher speeds?

6—Is there a serious objection to mixing cylinder oil with the gasoline and is there any advantage of it as a lubricant to the cylinders?

7—What may be the injury caused by using over tension on clutch springs? Is there an excessive pressure brought to bear on the crankshaft bearing by using tight clutch springs?

8—Is there a satisfactory fluid that can be inserted into the inner tube which will take the place of air?

Graysonia, Ark. AUTOMOBILE STUDENT.

—We have no record of any standard six-cylinder roadster weighing under 2,300 pounds.

2—No more underslung cars are listed among the 1915 models.

3—The main objection to this is that the lubricant which is suitable for cylinders is not suitable for gears. Gears require a viscous lubricant which clings to the surface and provides a substantial film between the teeth. The gear wheel must be able to carry the oil around with it. In the cylinder the oil requirements are entirely different. The difficulties of high temperatures must be met with and since an entirely different set of conditions are to be faced the oil will naturally have to be different if it is to provide ideal lubrication. Very often makers in the past have connected the gearset to the crankcase so that the oil in the latter worked its way to the former and vice versa. These makers have gradually abandoned the method however, as the oil from the crankcase was not considered to be ideal for the gearset. Another great objection to the use of the interconnected gearset and crankcase is that the car user would often put heavy oil in the gearbox with the result that it would work its way into the crankcase and cause carbonization of the cylinders.

4—The size of the tires is not the all-important factor in determining the proper gear ratio as there are many other points to be considered, such as the most efficient speed of the motor, the weight of the car, etc. These may so alter the proper gear ratio that the mere size of the tires becomes insignificant in determining the final reduction. With this in view, it is impossible to state that any given final reduction is best for a given tire size.

5—If the gearbox is well laid out in the first place, the changing of the lowest gear ratio alters the proper progression from one gear to another. In most instances the gearbox is laid out on either a geometric or arithmetic progression. Therefore, if the lowest ratio is changed, it will throw the proper progression from one gear to another into disarrangement and therefore, should not be done unless the gearbox is incorrect in the first place.

6—There is no objection to mixing cylinder oil with the gasoline. It serves as a lubricant to the cylinders and is claimed by many to be an advantage especially as regards two-cycle motors.

7—If the clutch is properly designed with a thrust bearing, there will be no pressure brought to bear upon the crankshaft bearing by the clutch springs. The big objection to too tight an adjustment on the clutch spring is that it will make the clutch grab instead of giving it a gradual engagement.

8—There are many fluids which have been inserted in the inner tube to take the place of air but none of them have come into any extended use, the main objection having been that they were not resilient enough or that they crumbled under the stress of rough roads.

Lever Slips Out of High Gear

Editor THE AUTOMOBILE:—I have had some trouble with slipping out of high on my Cole eight while going down grade and could probably remedy it if I knew what to look for. What would you suggest? H. W. KIMBALL.

Haverhill, Mass.

—It is very likely that the lower end of the control lever has been fitted too tightly against the shifting bars in the gearset. By removing control lever and reducing the diameter of the boss which enters into the shifting gears your difficulty should be eliminated.

Lincoln Highway Office Is in Detroit

Editor THE AUTOMOBILE:—Can you tell me where I can get information on the Lincoln Highway, the route and distance to San Francisco?

Montrose, Mich. C. A. WALKER.

—You can get full information on the Lincoln Highway by addressing the Lincoln Highway Assn., Free Press Bldg., Detroit, Mich.

Welding May Save Crow-Elkhart Cylinder

Editor THE AUTOMOBILE:—I have a Crow-Elkhart car and the motor block is broken so as to be beyond repair. I wonder whether you could tell me where to get parts for it. I also need a piston, connecting-rod, wristpin and bushing and connecting-rod bearings.

Newark, N. J. H. J. ANDERSON.

—Parts for the Crow-Elkhart car can be secured from the Puritan Machine Co., Detroit, Mich. Before giving up the cylinder casting however, you should take it to a good welder and have it gone over. Many an apparently hopeless job has been repaired by the welding process.

To Find Leaking Battery Cell

Editor THE AUTOMOBILE:—I have a 1912 Cameron runabout which has given me trouble with the differential gear. The cogs in the small differential pinions have broken off three different times. The car is equipped with 32-in. wheels, but was intended to use but 30-in. wheels.

1. Can you explain how I can remedy this trouble? Where can I get repairs for this car?

2. How can you tell which cells in an L. B. A. storage battery are leaking?

3. Is there a paint or chemical which will stop the acid from eating away the metal with which it comes in contact?

E. WEAVER.

Attica, O.

—As THE AUTOMOBILE has no record of anyone who is selling parts for the Cameron car, you will have to have new gears made or have the teeth repaired by having new teeth cut and fastened to the old gear. It will probably be

cheaper and better to have new gears made by a factory equipped to do this work and in all probability it will have to be handled by one of the large orphan car specialists.

2. The only manner in which you can tell which cells of a battery, Fig. 2, are leaking would be to fill them all to the same level with distilled or clean rain water, then after allowing the batteries to stand in a dry place for twenty-four hours, look at the height of the electrolite in the different cells and if there is any difference in the level, the one which is lowest is the one which is leaking.

3. The material used for protecting wood and metal against the inroad of acids, such as is used in storage batteries, is lead or lead paint.

Double Magneto for High-Speed Work

Editor THE AUTOMOBILE:—I have a 45 foreign Fiat T-head motor and would like to install a two-point ignition. Would you advise me how to couple same with a Bosch three-magnet H. T. magneto? Also, how much power would this give? What would be the extra stress on the engine and whether it would be able to stand same?

2. Can a steering wheel be changed from stiff to adjustable rake, and how?

3. Could you give me a diagram of the oiling system on the 1909 Fiat?

4. Could you tell me where I can obtain a book on construction and care of the 1909 Fiat or a car of similar make? The Fiat Co. could not furnish me with same.

5. Please give me the strongest solution to place just in the cylinder jacket, not in the radiator. Would lye do, and how long should it stand to loosen rust and corrosion?

Jersey City, N. J. A. MECHANIC.

—If you intend to use the car for high-speed work, two-point ignition would be very satisfactory and can be secured in two ways. First, by coupling the plugs in multiple by means of special plugs for the purpose, and secondly, by changing the magneto for one with a double distributer. If you intend to use the car for speed work it would be better to change the magneto, but for ordinary work it would hardly be worth while to go to the expense of changing it.

2. The steering wheel itself cannot be changed, but you no doubt refer to the column or post, which can be lowered or raised to any desired position.

3. THE AUTOMOBILE has no diagram of the foreign Fiat on hand. As the American car is quite similar in this respect, however, this diagram is given instead in Fig. 3.

4. A book on the care of the American Fiat can be secured from the Fiat Repairs Co., 640 West Fifty-eighth Street, New York City. This is practically the same as the foreign car.

5. The best way to remove the rust would be to take the cap from the top of the cylinder and scrape the rust from the water jacket space.

Piston Slap May Cause Knock

Editor THE AUTOMOBILE:—As a service man I have found in repairing and adjusting a motor, a knock which I cannot place or eliminate. In the first place, when the car was brought in, there was no knock. It was brought in for more power. We put in new patent rings, scraped carbon and ground in the valves. After this was done the knock came. It is really a tap, almost like a low tappet sound. We then took out the valves, thinking the stems were sprung. We had them all trued and faced off, then ground them in again. The knock was still there. We then put in new wristpins and bushings. Still it was evident. Last of all we raised the cylinders with fiber plates 3-16 inch, but to no avail. Where is the knock?

Holyoke, Mass. H. O. S. S.

—You have not mentioned piston slap which is a possibility due to the fact that the pistons might tend to oscillate about the patent rings in the top of the cylinders and slap at their lower end. Another possibility is that the rings do not fit tightly enough in the piston grooves thereby giving a backlash at the end of each stroke. The crankpin and crankshaft bearings also should not be overlooked.

Power Not Accurate by Formula

Editor THE AUTOMOBILE:—Can you give me a way to calculate the power of motors to determine the exact brake horsepower?

Jonesville, S. C. H. W. L.

—It is impossible to calculate accurately the horsepower of a motor by formula. If this were so, the formula would have to include every possible variable, because if it did not, it would be incorrect for every value of that variable except one. Since the power developed by a motor includes such things as cam contours, manifold and port designs, shape of combustion chamber, tightness of piston rings, frictional horsepower, losses through the bearings, etc., it is obvious that a formula which can furnish brake horsepower is impossible.

Three Possible Causes for Knock

Editor THE AUTOMOBILE:—I drive a 1911 Hudson 33 which is in good order and will run smoothly and quietly if I keep it at a steady speed of from 16 to 25 miles per hour, but after stopping it will knock until I gain spee dagain. The car runs with this knock in running slowly or in starting. Retarding the spark makes no difference. Can you suggest a remedy?

Mansfield, Mass. S. F. FRENCH.

—There are three possible causes for the knocking. One, excess of carbon; two, a loose connecting rod; three, a loose bearing. First try removing all the carbon by having it scraped or burned out, and if this does not cure the trouble, the motor should be taken down and the bearings inspected for looseness. What is known as a gas knock often develops from a badly adjusted carbureter.

ACCESSORIES

Kemco Electric Starter

THE Kemco Electric Mfg. Co. has brought out an additional unit for starting which can be used in connection with the fan type dynamo. This makes up a two-unit starting and lighting system which can be fitted to cars not originally equipped with electric cranking. The cranking motor is designed to fit on the front of the car, replacing the hand crank, and to duplicate the action of hand cranking. When the switch button is pressed the same starting clutch as would have been employed with a hand crank is slipped into engagement with the crankshaft and the motor is spun until it fires. When the engine starts under its own speed the starting clutch is automatically thrown out in the same manner that the hand crank is thrown out of engagement when the engine starts.

The system works at 6 volts and should be installed in connection with a 100-ampere hour storage battery. The starter is made in two different sizes so that all classes of cars are covered. The gear ratio between the armature of the cranking motor and the crankshaft is 9.5 to 1.

Some of the special electrical features in connection with this machine are particularly its automatic action in engaging to the crankshaft by means of a magnetic control when the starting button is depressed. The release is altogether independent from the solenoid coil which engages the cranking motor with the crankshaft, being due as explained, to the declutching of the cranking motor. The starter is controlled by the car operator by a button depressed by the foot. It can be applied to practically any make of car by means of universal fittings which attach across the front of the frame and are adjustable in every possible way so as to fit the car properly. With this arrangement no drilling or machine work is necessary.

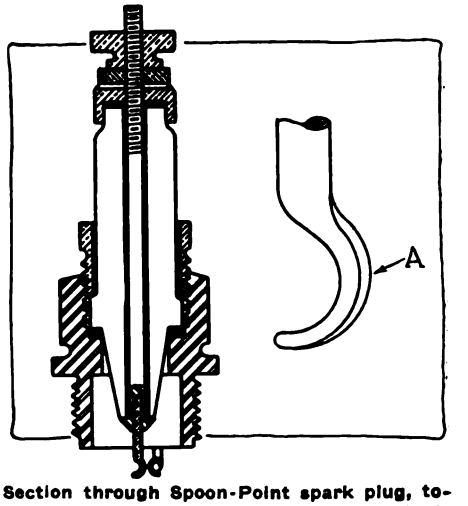
In connection with the new cranking motor there is also brought out a positive drive for the Kemco fan generator. This gives an improved two-unit starting and lighting system with which a car can be completely electrically equipped.

The overall dimensions of the cranking motor are 9 by 7 inches. Its weight is approximately 33 pounds and since the weight of the generator is 11 pounds, the two principal units total less than 50 pounds.

A special two-unit electric starting and lighting system for Ford cars has also been brought out, operating on the same principle as the larger one but adapted especially for the Ford. The entire outfit, including the electrical fittings, lamps, side lights, tail lights, wire, etc., is $95 for the Ford, $125 for medium size cars and $150 for large cars.—The Kemco Elec. Mfg. Co., Cleveland, O.

Spoon-Point Spark Plug

Of conventional design, except for the shape of the terminals, the material of which is a new alloy, the Spoon-Point spark plug has entered the field. The terminals are spoon-shaped, as may be seen in the accompanying illustration, the spoon being 3 millimeters in diameter, the convex surface about 1 1-2 millimeters above center, and the concave surface about 1 millimeter deep, giving an unusually large sparking and wearing surface. The inside convexity of the terminals is claimed to prevent the accumulation of oil and carbon between the terminals, and produces a flat circular spark which is not diffused, but hot and effective, while the concave construction affords a drain for oil.



Section through Spoon-Point spark plug, together with detail of spoon-shaped terminal

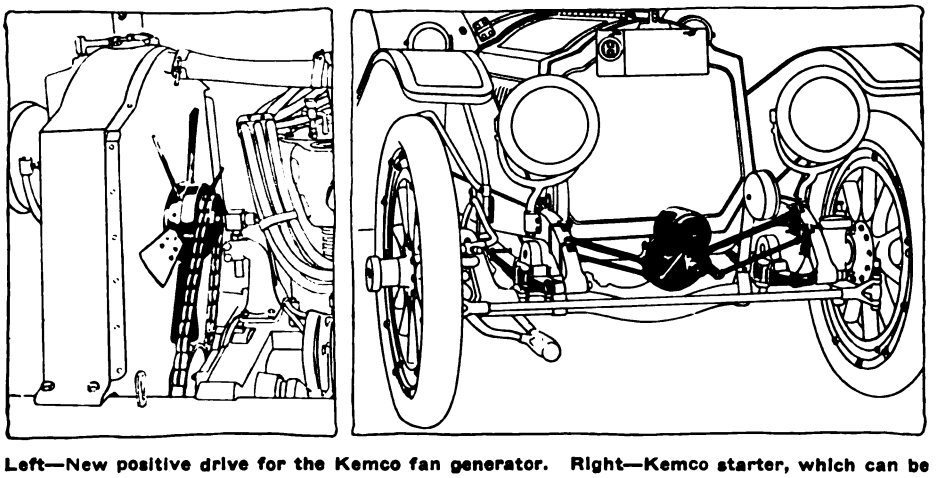
A feature of this plug, in addition to the distinctive shape of the terminals, is the white alloy manufactured after a secret patented process which is used for the terminal spoons. This alloy is somewhat lighter in color than platinum and is claimed to be very durable and especially suitable for spark plug work, remaining bright under the most intense heat, regardless of the amount of oil used in lubricating the motor. The porcelain to be used in Spoon-Point plugs is also a special process product, patent application now pending. Ordinary porcelain is being used until this patent is granted. The manufacturer guarantees these plugs and will replace any defect in workmanship or material, free of charge. Plugs will sell at retail for $1 apiece.—Spoon-Point Spark Plug Co., La Porte, Ind.

Lock Switches

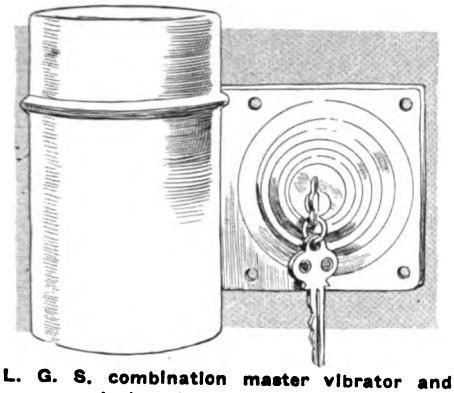
Master vibrators are popular attachments for Ford cars and the L. G. S. is a combination of vibrator and lock switch. The switch is a Yale lock job and nothing can be done with the ignition as long as the lock is thrown open. The same switch lock can also be had without the vibrator, and the attaching screws are so arranged that they cannot be withdrawn when the current is locked Off. This effect is obtained by making the heads of the screws accessible through holes in the cover plate, and when the key is turned pieces of brass are drawn across the holes. The switch alone costs $3 and the switch combined with master vibrator $12.—Bass-Moody Co., Peoria, Ill.

Universal Test Clips

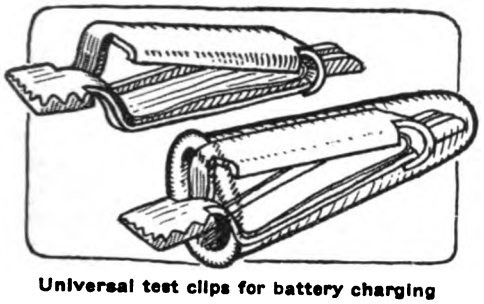
For making quick connections the Universal test clip has been brought out to fill the field in ignition and battery charging service. These are manufac-



Left—New positive drive for the Kemco fan generator. Right—Kemco starter, which can be used in connection with the fan type generator



L. G. S. combination master vibrator and lock switch for Ford cars



Universal test clips for battery charging

tured under different numbers pertaining to different types and examples of their construction, types 8 and 9 being illustrated herewith. The clip generally used by the automobile trade is No. 13-A, a 20-ampere lead plate design used chiefly for charging the batteries which come with the electrically equipped gasoline cars. Automobile manufacturers who receive these batteries in quantities line them up on great long tables and by means of jumpers fitted with Universal test clips connect the batteries up in series for charging. The jumpers are made by taking a piece of lamp cord 15 to 18 inches long and fitting the test clips on each end.

The battery charging stations and garages which have occasion to recharge these batteries also find use for the clips as a quick and ready means of making a connection. The teeth of the clips will bite through the corrosion on battery terminals, thus making it unnecessary for the garage man to clean the terminals.—R. S. Mueller & Co., Cleveland, O.

Spranger Rim and Wheel

This is a form of wire wheel which has the demountable rim feature and comprises a standard form of rim holding the tire, which rim fits onto a steel channel felloe to which the wire spokes run. Pairs of lugs are welded at equally spaced intervals around the inner surface of the rim, there being either three or four sets, depending upon the size. These lugs fit into slots cut in the channel sides of the felloe and make the firm attachment of the two parts. On the felloe is the locking mechanism shown in Fig. 1. The dogs A which are pivoted to the felloe may be swung outward by the threaded nut B on the bolt C. When the rim is in place, the bolt is turned and the dogs then enter slots cut in the adjacent sides of the lugs on the rim, preventing the latter from coming off. To prevent the bolt from turning, a flat piece of steel goes over the head and is held in place by its springing into a small indentation in the channel side of the felloe.

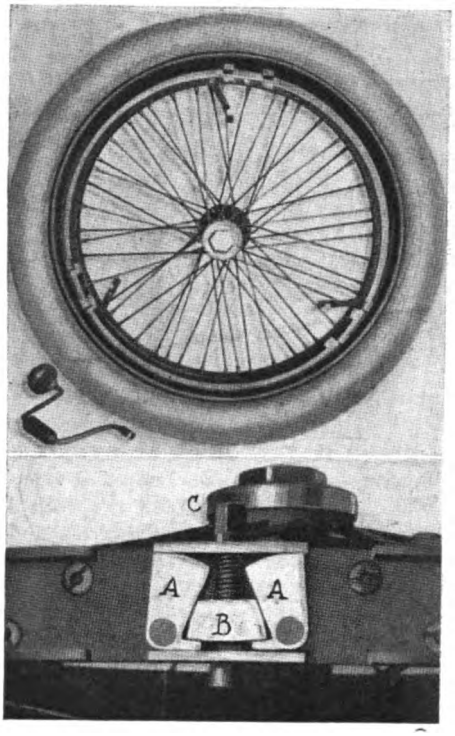
With this demountable feature, it is pointed out that the wire wheel is as simple to have as the wooden type. It is not necessary to carry extra wheels but simply the rims as would be the case with wood types. However, the Spranger concern makes this wire wheel with the demountable hub feature as well, the locking method being by means of two hub caps screwing on in opposite directions and thus holding each other in place.—Spranger Rim & Wheel Co., Detroit, Mich.

Johnson's Wax Body Polish

With the idea of meeting the need for a protection for the high finish of the body, hood and fenders of all sorts of cars, S. C. Johnson & Son are manufacturing a hard, dry wax, which they claim prevents both dust and water from sticking to the surface. This wax has long been used for polishing woodwork, floors, furniture, pianos, etc., which suggested to the makers that its quality of holding luster indefinitely because of its hard, dry impervious nature, would render it of value for automobile work. The wax is said to cover up small scratches, an advantage being that it is said to produce as fine a finish over varnish of poor quality as over that of high grade, the wax acting entirely independent of the original finish on the car, and being equally effective as a protective agent, irrespective of the condition of the surface to which it is applied.—S. C. Johnson & Son, Racine, Wis.

Steering Steady

To prevent the sidesway in a Ford car due to the construction of the spring assembly wherein both front and rear springs are hung between two shackles or links that are free to move sidewise, is the purpose of an invention known as the L-A Steady Steerer. It consists of a strut as shown in the illustration which



Upper—Spranger wire wheel with demountable rim. Lower—Locking mechanism

is so connected between the body and the axle as to hold the latter in a position that will cause the road wheels to remain in a straight course set by the steering wheel. It accomplishes this by drawing the axle sidewise on upward movement, and by pushing it on downward movement, keeping the relation constant.

This is advantageous because, it is pointed out by the maker, whenever the Ford machine not equipped with the steerer receives an axle side pull sufficient to overcome the weight of the body, which weight ordinarily holds the body, central on the chassis, then the axle moves sidewise in exact proportion to the force exerted.

In application, the end of the strut attaching to the frame is fitted with a spring bolt to take the place of one of those ordinarily attaching spring to frame, while at the axle end it attaches to the regular link bolt which connects between the link and the spring shackle. —Lockwood-Ash Motor Co., Jackson, Mich.

Four Cylinders and Their Future

Is There a Market for the $1,000 Four?—Some Thoughts Suggested by Gossip on the Recent Society of Automobile Engineers' Trip

By A. Ludlow Clayden

THE past, present and future position of the four-cylinder automobile in America has been a favorite subject of discussion among engineers for several years, but on board the steamship Noronic on the recent summer session of the Society of Automobile Engineers it seemed to rival any other topic when three or four engineers got together between the meetings. The writer, having taken a share in several such informal conferences, finds, after a week's reflection, that there arise upmost in his recollection a few leading ideas on which agreement seems fairly general.

First of these, without a doubt, is that the four-cylinder motor has seldom, if ever, been given a proper chance to show its quality, because it is in isolated instances only that it has been made with an eye to anything but low production cost.

Making a Cheap Motor

Now, there is only one way, as a rule, to discover or create an inexpensive *good* article of any kind and that is to make it good first and cheap afterwards. Since engineers have discovered how to make good sixes and good eights, to say nothing of good twelves, hardly anyone has had the time to make a four along similar lines, and it is safe to say that nobody has, till recently, given deep attention to the possibility of creating a really good four-cylinder motor that could find a place in a $1,000 chassis.

There are, of course, motors which are used in cars of about this price whose manufacturers would consider them good motors, and they *are* good from several viewpoints; but they are not modern designs of the high-speed, high-efficiency type directly comparable with the eights. We have nothing on the motor market that resembles one-half a Cadillac, for instance.

There are some big fours of excellent design and comparable with any modern work at home or abroad, but these are in fairly high-priced cars and are not to be bought for assembly manufacturing. Yet, considering what we now know concerning the cost of making a highly efficient eight of dimensions approximately 3 by 5 in., it seems reasonable to suppose that an equally well made four *could* be produced at a price which would make possible its incorporation in a $1,000 car.

Buyer's Taste a Question

It is obvious that such a motor would give us only about one-half the power of a 3 by 5 eight or two-thirds that of a six of similar dimensions, though in practice the power should be a little in excess of this proportion at equivalent crankshaft speeds, so we come to the point of wondering whether the power available is enough for any sort of automobile that the American user would accept.

Question: Is there still magic in the words six and eight, or is it the absence of the kind of car we are considering that makes the absence of the demand?

Or putting it another way: Will the man who now uses a $720 four pay another $250 for a little more power, much smoother running and much better finish on a car of the *same size.*

The writer, realizing how greatly conditions differ both as to service and to public taste on opposite sides of the Atlantic, always hesitates to bring in any argument based on European experience solely, but in this connection it is not out of place to just mention the fact that the well made, small size and rather costly car was an experiment when it came on the European markets. Europe has not had any good $1,000 cars to carry four people, but that is a matter of quantity only. There are several British and French automobiles of four-passenger capacity which are regarded as good material, workmanship and finish, that could easily be sold for this price if they could be made in thousands instead of hundreds. Now, the British and French buyer was very skeptical about these cars when they first appeared, very skeptical indeed, and it took experience to show him that their wonderful economy in upkeep combined with better performance than that anticipated made them desirable things to own. Might not the same thing reasonably happen here?

Who?

At this point comes the greatest divergence of opinion. The writer confesses to an open mind and merely observes that the engineers divide into two main camps, those who say that the American user thinks more of size than anything else, and those who say that "they would like to see some one else try out the scheme."

In estimation of the buyer's predilections the salesman ought to know, but it is the experience of many different sorts of business that the salesman often is too conservative. He hates to change a thing which is going moderately well for fear it should not be approved. He is a little loth to gamble on a new article.

Thus one may query the estimate of the public mind.

Quality Beats Quantity Sometimes

Taking the broad view, there are many things which the American man or woman likes to have of the highest possible quality regardless of cost. In fact, does not this apply to all the surroundings of daily life, to furniture, to homes, to food, to clothes even? There is no rush for the largest house, the largest chair or the widest menu that a given price will buy, so why should there be regard for bigness only in automobiles?

Here no doubt many of my readers will say, "That may be all very well for other places, but size for money has been the manufacturer's cry so long in the automobile field that it is too late to try any other tack." Well, it may be so, but there are many engineers and many manufacturers who do not seem to be so sure about it.

Precedent Broken by Eights

Perhaps the coming of the multi-cylinder motors after we thought that everything had settled down to sixes and fours has shaken convictions. Perhaps it was the ready way in which expensive cars of new construction were seized upon by the motorist, which has disturbed the tranquil attitude of two years back, but it *is* disturbed and there are chances

now for many novelties which had no chance till something happened along to shake the automobile industry to its very foundation; and, let it be remembered, the ultimate user, the customer, is a part of the industry, just so soon as he buys his first car, and he is shaken, too, with the rest of the trade.

A Household Parallel

America of all places in the world is the last where conservatism of the buyer need be considered as paramount, for in no other country on the globe are people educated to the point where the rapidity of advance of science and manufacture is realized. There are literally thousands of petty, labor-saving household tools and utensils in universal use in U. S. A. which could not be sold in any other market without an educative campaign spread over years.

Does this not really mean that if the manufacturer has something he knows is good, something which will give satisfaction to the man who buys it, it will take less effort on his part to make the buyer fall in with his views in America than it would anywhere else? If this is true, then it is not really necessary to think about the buyer and his supposed tastes, since it is possible to *create* a new taste with very little effort.

Now, given our small, but highly-efficient motor, we know that good road performance is obtainable by putting it into a car of a weight in proportion to its power. Half a Cadillac motor will pull half a Cadillac car. Can we make that half car is the question troubling many engineers.

It is, of course, obvious that we cannot make it to hold the same number of people, the load must also be in proportion, but, if we continue the Cadillac allegory, and assume that this car gives a proper power for seven passengers, then the half size motor should be almost equally at home with four passengers and well content with three.

Most of the cheap five-passenger cars on the American market to-day are not big enough for their rated load. They are comfortable for four, but a tight fit for five, and it is noticeable on the road that the normal load is three or four. Past four there is just as strong a chance of finding six or seven aboard as of the rated five. So it is open to question whether the nominal five-seat capacity is so important as some people would have us believe.

In conclusion, the writer again wishes to emphasize the fact that he is unconvinced either way. He sets up no pretense to be a judge of the buyer's taste, but when so many engineers and so many manufacturers are found discussing somewhat along the lines here expressed, the questions become matters that the motorist and the member of the trade ought alike to consider. Perhaps nothing will happen, perhaps much will transpire; it is far too early yet to offer even an opinion on the subject. The purpose of the writer is to throw a little light on some straws which are fluttering in the breezes of Michigan and Ohio and have not yet taken a sufficiently settled position to indicate the way the wind is going to blow.

Argentina an American Automobile Market

AMERICAN-MADE automobiles are steadily gaining in popularity in the Argentine market, their proportion of the total imports of automobiles into that country having risen from 10½ per cent in 1912 to more than 19 per cent in 1913, the latest period for which detailed official returns are available.

The imports of automobiles into Argentina during 1913 were valued at $5,194,200, supplied chiefly by France, the United States, Germany, Italy, the United Kingdom, and Belgium, in the order named. While France still ranked first in the importation of automobiles into Argentina in 1913, the United States made a larger actual and relative gain than any of the other countries named, and rose from fourth place in 1912 to second place in 1913. In 1914, when the world-wide depression reduced the value of automobile imports into Argentina to about one-fifth of their normal total, those from the United States also decreased, the exports of automobiles from the United States to Argentina and other countries of South America in that year being a little over one-third of those of the preceding year.

Exports from United States

The imports of automobiles into Argentina during the last four years were as follows: 1911—2461, valued at $2,346,600; 1912—4281, valued at $5,159,000; 1913—5115, valued at $5,194,200; 1914; 2185, valued at $1,105,700.

Exports of automobiles from the United States to all countries increased from 329, valued at $2,833,154, in April, 1914, to 5345, valued at $8,045,222, in April, 1915. This growth was almost exclusively in commercial automobiles, of which the exports rose from 52, valued at $72,676, in April, 1914, to 2267, valued at $5,240,481, in April, 1915. About half of these commercial automobiles went to France and the remainder chiefly to England and other European countries. In the 10 months preceding May 1, 1915, exports of passenger automobiles aggregated 14,641, valued at $12,356,472, as against 23,167, valued at $20,664,480, in the corresponding period one year earlier; while those of commercial automobiles numbered 8580, with an aggregate valuation of $23,977,968, compared with 595, valued at $934,330 in 1913-14.

Road Dust in Cylinders, Etc.

(*Continued from page* 18)

anism with a lot of exposed parts and journals and electrical connections and then actually suck all the dirt there is around the country in upon it."

Mr. Jehle cited German experiments to the effect that it was more important for cooling purposes to subdivide the air into small parts than to subdivide the water.

On the whole it was generally admitted at the meeting that the current of air which the fan of the average car is capable of drawing in through the average radiator is very wastefully applied, from which it would follow that the total area of air intake, at the front or rear of the radiator or behind the fan, could be reduced without harm if the means used for this purpose involved a more equable distribution of the air supply in all portions of the radiator and less violent counter-swirling of the air once it was under the hood. The problem of reconciling and combining such improved construction with provisions for filtering or precipitating the road dust before it reaches the carbureter is now bidding for an experimental solution which in course of due time may find its way into standard design.

For the first experiments it may perhaps be preferable to determine the dust question independently of all complication with the efficiency of the cooling system and to erect a filter box of ample dimensions around the whole carbureter, including hot, cold and auxiliary air intakes, but if the premises are found correct, according to which there are faults to be remedied at the primary air intake through the radiator as well as at the secondary intakes in the carbureter, the prettier and more thorough improvement must evidently in the long run be one which strikes the evil at its root, excluding dust from all air entering under the hood.

Among desirable data, meanwhile, would be such as would make it clear whether dusty country driving produces carbon deposit more rapidly than city driving, under otherwise equal conditions.—M. C. K.

Studebaker Refines Four and Six

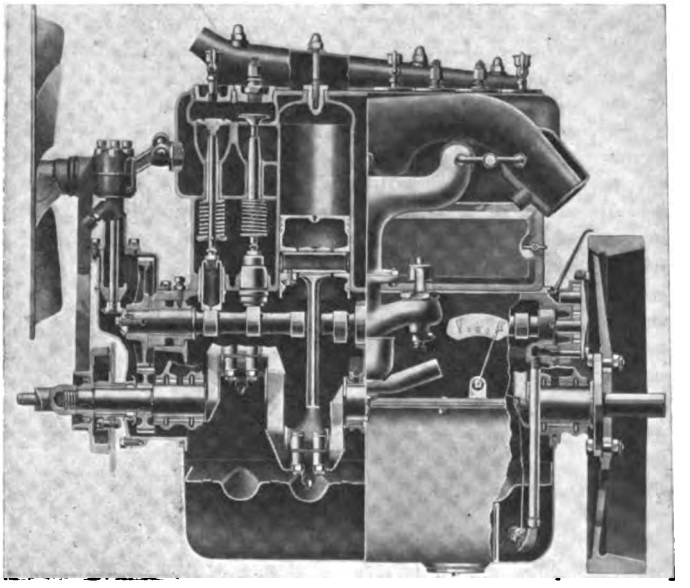
Cars for 1916 More Powerful, Larger, and Sold at Lower Price —Standardization of Parts Lessens Cost of Manufacture

GREATER standardization of the parts entering into its two chassis—four and a six—and further attention to production make it possible for the Studebaker Corp. to bring out its new models in larger and more powerful form at reduced prices.

The price cut is most emphasized in the six, which is to sell at $1,050 as a seven-passenger touring model, and $1,000 as a roadster. For the previous seven-passenger six, the price was $1,450. In the seven-passenger touring model on the four-cylinder chassis, the cut has been $100, making it $885; while the new roadster is $135 less than previously, or $850.

The bodies are practically alike on four and six chassis and most of the difference in wheelbase is taken up by the engine. The cars are made to conform to the same general design throughout, so far as possible. In fact, they are much more similar this year than ever before, and practically the only differences in addition to the difference in number of cylinders, are the wheelbase, rear axle gear ratio, and rear spring size.

This standardization is reflected in the prices.



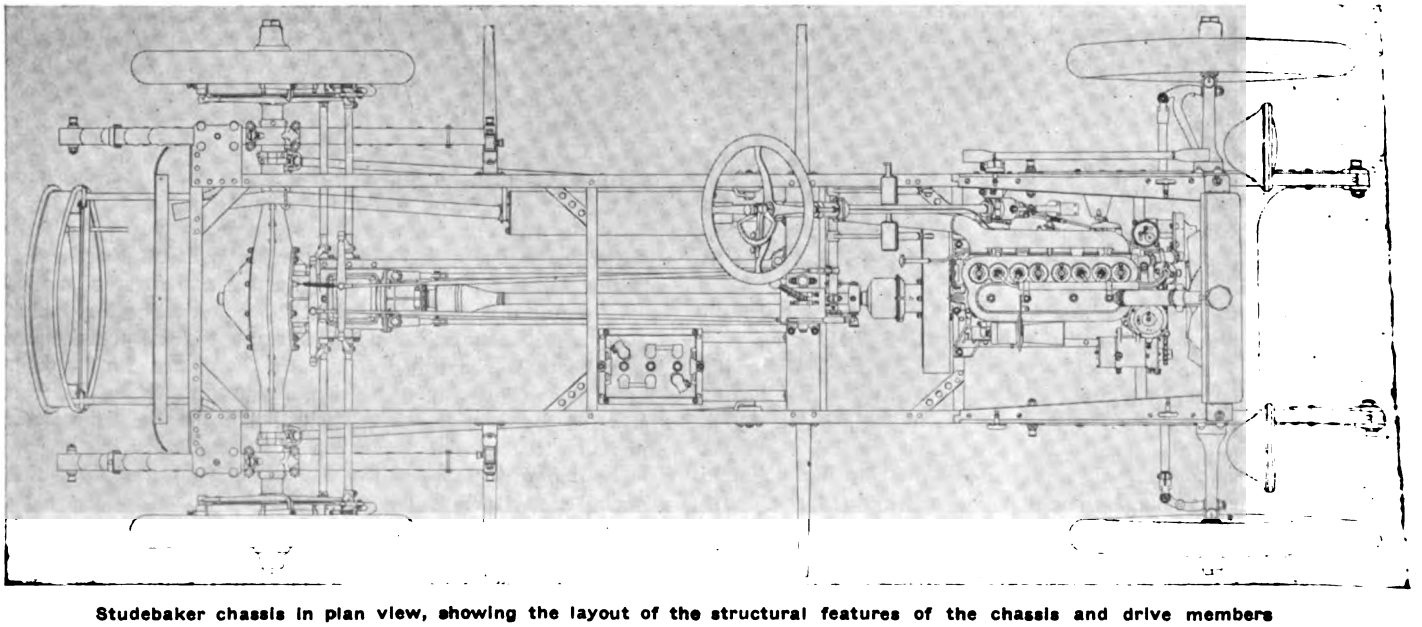
Studebaker four-cylinder motor similar design to six used for 1916

Greater Accessibility

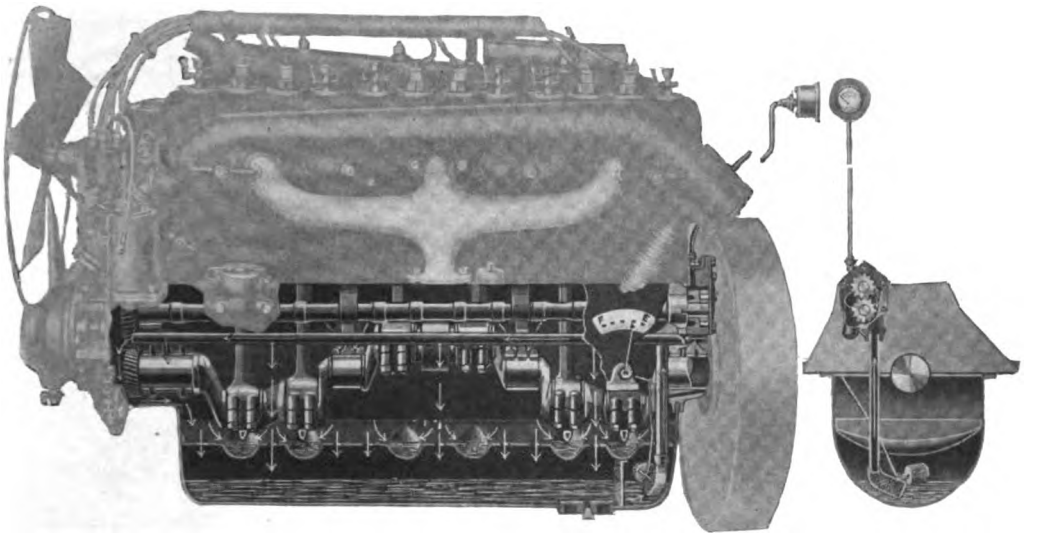
One of the main changes in the cars as compared with the previous types is in the redesigning of the engine for greater accessibility and quietness along with more power. The bore has been increased from 3½ in. to 3⅞ in., the stroke remaining the same as it was, at 5 in. The cross-shaft at the front has been removed, and there is a big change in the manifolding. The wheelbase has been lengthened on both chassis, the six getting 1 in. more, making it 122 in., and the four having 4 in. added to give it 112 in.

Improvement in the clutch, enlarging of the propeller shaft, a general smoothing out of the lines of the bodies, changes and simplifications in the electric system and the wiring, the use of real leather upholstery and some other minor improvements in the chassis and frame are points which will indicate that although Studebaker has seen fit to come down in the prices of its cars, there has been no curtailment of their value. In fact the cars are larger, more comfortable and have greater power.

In general, however, characteristic Studebaker design still holds in the mechanical make-up of the cars. The gearset is still in combination with the floating rear axle; a cone clutch is used; the Wagner electric lighting and cranking combination is employed, and the gasoline tank is in the cowl.



Studebaker chassis in plan view, showing the layout of the structural features of the chassis and drive members



Refined lubricating system as used in the six-cylinder model

The increase of the bore of the motor, together with the other alterations, add about 22.5 per cent to the piston displacement of the powerplants, and it is claimed that an even greater percentage of increase is made in the horsepower. The six has a displacement of 353.8 cu. in., and is rated by the maker at 60 hp., while the four has a 235.3 cu. in. capacity with rated horsepower of 40.

Cross-Shaft Removed

Probably the most important change in the engine design is in the removal of the cross-shaft at the front. This was spirally driven from the camshaft gear and operated the water pump on one end and the ignition distributer on the other. Now the pump is driven from the camshaft gear on the left, and the distributer is vertical and operated through bevel gear connection with the front end of the camshaft. The other unit affected by the change is the generator, which now sets on end with its armature shaft vertical and has spiral gear drive from the front gears. This is on the right forward side.

The starter motor is also placed at the front and on the right side. It is arranged horizontally and drives the crankshaft through a roller chain connection and a housed-in train of reduction gearing. The chain is not inclosed, and is compactly placed between the fan pulley and the gear housing. The driving sprocket has nine teeth, and the sprocket on the crankshaft end has forty teeth. In the front gear driving system of the new motors, the matter of silence is provided for by the making of the mainshaft and generator gears of case-hardened steel, with the camshaft gear of cast iron. This gives steel running against iron.

Manifolds Redesigned

Another big change is the abolition of the internally-cored passages for the distribution of the gases to the cylinders. The carbureter formerly occupied a position on the right side, and the gases thus went through the water jackets to the valves on the opposite side. Now, however, Studebaker has gone back to the original method of placing the carbureter on the valve side, and using separate manifolds to get the gases to the intake openings. It is believed that by using these manifolds with smooth and uniform passages, the power is augmented, for there is less friction. Cored passages are bound to be somewhat rough on the inside, and then, too, it is difficult to make the section uniform. With this new intake manifold construction, the exhaust header is shaped so that the intake piping can go below it without interference with the valve cover.

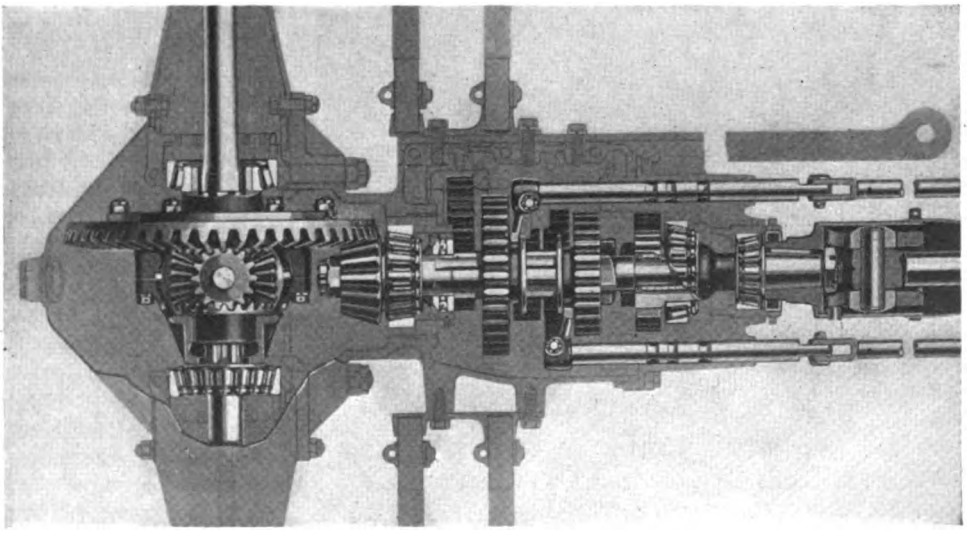
Along with stiffer rods and larger crankshafts, the pistons have been lengthened 5/8 in. to make them 4 5/8 in. long. The pins now are secured to the pistons by set screws, which is in contrast to the old method of pressing them into the rod end with bearing in the piston bosses.

A change has also been made in the tappet design, making it much easier to take them out if necessary. They used to be made of mushroom shape, that is, with the big end at the bottom, making it compulsory to take them out through the crankcase. Now they are the same diameter all the way down, so that they can come out through the top as soon as the valve and spring are out of the way.

Oiling System Altered

There is a change in the circulating splash oiling system, which is conducive to a more positive oiling at low engine speeds. The former plunger pump located on the side of the crankcase and driven by a camshaft eccentric has given way to a gear pump on the rear end of the camshaft. This also does away with the slight noise which the old type made. Also, the sight feed on the dash has been replaced by a pump pressure indicator.

A very clever improvement over the former wiring of the electric system is made in the fitting of a junction box. This box is placed on the right rear side of the engine where it is very accessible. All wires go to this box, and there is practically none on the body with the exception of that going to the control apparatus on the instrument board. A cover



Rear axle and transmission system which has been continued in the refined models

plate over this junction box held by four screws gives access to the wiring connection for the entire system. As this box is very close to the motor generator and starter, the wiring is consequently very short from them. All of the wires run through waterproof conduit, and as the system is of the one-wire type, it is doubtful if a more compact or simpler wiring layout could be worked out.

Should it be necessary to remove the body from the chassis, the minimum disturbance of the wiring would be necessary, due to this mounting on chassis and motor. Further, it is usually considered that the greatest troubles from the electric systems of the modern car are due to the working loose of connections, and as most of them on these new Studebakers are a part of the rigid portion of the machines, any body movements will not affect them—factors which should make a very efficient electrical system on the whole.

Six-Volt Electric System

The storage battery, a 100-amp.-hr. Willard, is placed under the right front seat and attached to the frame in a special hanger. The electric system operates at 6 volts, and though the starting unit is smaller and of lighter weight, it is said to be more efficient, cranking the engine at higher speed through being geared higher.

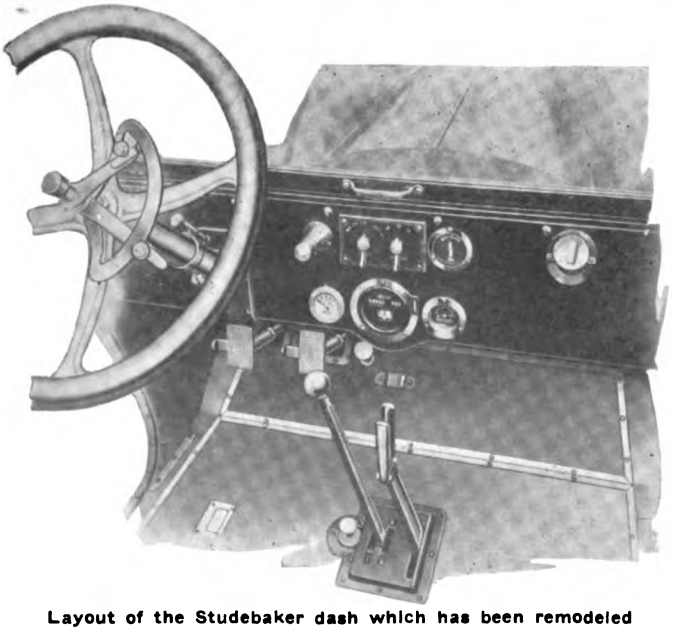
In the clutch a change has been made to make this unit more serviceable. The former bronze clutch collar has been replaced by a ball-bearing throwout, this tending to less wear and requiring less attention.

The propeller shaft has been made more substantial and whipping has been prevented by increasing the diameter from 1⅛ in. to 1 5/16 in. The shaft is an alloy steel design, fitted with a universal at either end.

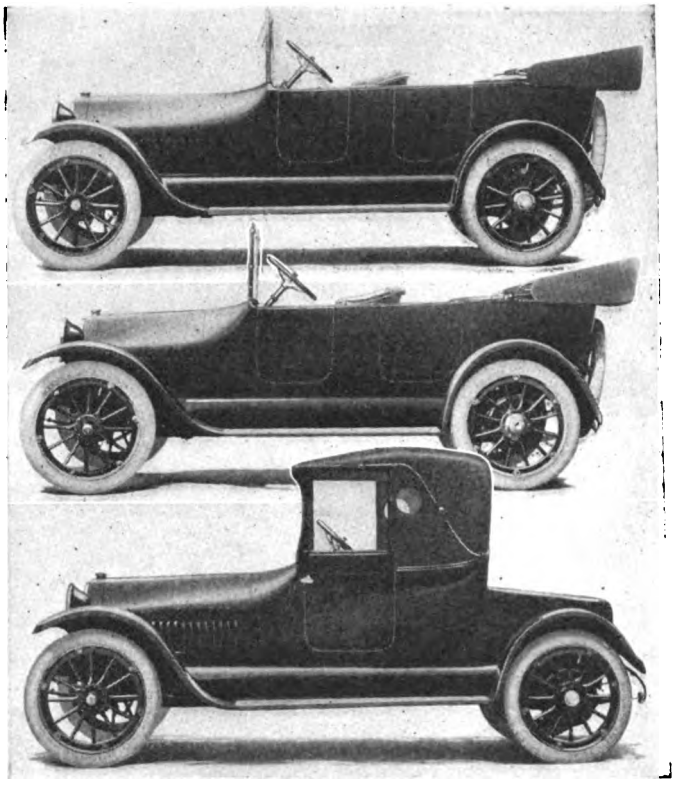
The gearset bolts through a flange to the pressed-steel housing of the rear axle, and on the left side of it is attached a pressed-steel torsion arm which runs forward to a mounting on the intermediate frame cross-member. Radius rods run forward to the frame side members to do their part in preserving axle alignment.

Brake operating shafts and equalizers are now carried on the rear axle unit, and the brakes and radius rods now swing on the same center making for uniform brake action regardless of car load. In the gearset there are no changes, but the axle housing has been made heavier. The four-cylinder chassis has an axle ratio of 4 to 1, and that of the six is 3.7 to 1.

The entire spring suspension has been gone over, and on all cars three-quarter elliptic rear springs are fitted, these being underslung from the axle. They measure 51 in. rear and 38 in. front on both cars. The previous four has elliptic rear springs, although the six used three-quarter elliptics. The cars are lower hung than formerly also, this being brought about by the lowering of the rear springs along with the dropping of the front axle at the spring seats.



Layout of the Studebaker dash which has been remodeled



Studebaker bodies for the 1916 season, showing from top six-cylinder seven-passenger, five-passenger design and coupé

Frames have been strengthened by having fewer holes in them, and these are not in line, so that no weakening should result. Another minor chassis detail is the fitting of a long tail pipe to the muffler to avoid noise under the body.

Tires are 34 by 4 on either chassis, this being an increase on the four which formerly was shod with 33 by 4's. Straight sides are used, the rear set being of the safety tread type. A new form of rim is also supplied, the main feature of which is a special form of pawl lock which makes it easier to detach the tire.

The wheelbase increases give more body room, and along with this, the bodies are well proportioned and of excellent lines. The back of the front seat has been shaped to fit the back, really making an individual back for each of the front passengers. A new form of auxiliary seat is provided. These fold into compartments in the floor of the tonneau, and when not in use, they are flush with the floor. But when unfolded, they leave a sub-floor exposed, and in this the seat occupant can comfortably put his feet.

These comfort features taken together with the fact that more attention has been given to balance than ever before, so that vibration and motor noises have been materially reduced, gives a more efficient power-plant as well as a more efficient chassis. Heavier dimensions in critical parts from crankshaft throughout the entire chassis are in a measure responsible for the excellent results.

In the control of the cars, the improvements are principally the providing of adjustable pedals, and the locating of the starter pedal more conveniently at the gearshift gate. A new dash arrangement has also been effected with the instruments all grouped for one light. The rotary electric switch has been removed from the heel board and mounted on the dash, and a lock is provided for the ignition switch. A vibrator type of horn has given way to a Sparton.

The Automobile

Aluminum Pistons

ONE of the significant points of the S. A. E. summer session was the fact developed that aluminum pistons are here to stay. They have come as only another interpretation of the practically universal trend towards small bore and high speed.

Granted then, that this field has been opened to the aluminum foundrymen and the aluminum piston has been accepted, there are still some points which have not been reduced to standard practice. The formula for the alloy itself is still in the trade-secret class and naturally the subject of a difference of opinion. The exact clearances necessary are still debated and the reinforcing of the piston head to take care of the effect of the high temperatures on the strength of the material is a necessary precaution which must not be underestimated.

These and the other technical questions must be studied by the foundrymen because there is no doubt in the light of present developments that the car designer is going to call upon them to furnish these light castings. In the discussion at the S. A. E. meeting on the Lakes no one brought any serious objection against the light pistons, and now that the engineers of the automobile industry have given their approval it is to be expected that cars regularly equipped with these pistons will rapidly increase. In meeting the demands for light weight in pistons aluminum alloys are today occupying the position that cast steel was booked to take.

100 Miles Per Hour

FIVE HUNDRED miles in 5 hr., almost if not quite, for 7½ min., less would have done it! Pause and think, for it is truly something worth thinking about.

What does it *mean?*

This perfectly prodigious speed means that firstly, the machine has been created of the needed power and stamina; secondly, that the air-filled tires have been made to carry the machine and transmit the power; and thirdly, that the track has been built on which such a machine can run in safety.

For the track, all credit to those who constructed it, but no deep problems of science had first to be mastered.

For the tires, the mechanical clear thinking which produced the cord construction and the labor of rubber experts calls for praise and admiration.

For the machine, we have to make acclamation to thousands of engineers and thousands of metallurgists of many nations, who together have devised new and ever new ways for loading metal as it never was loaded before, and for making new metal to bear the stress.

Like all marvels of this age, we, a people dulled to appreciation by ever-repeated wonders of mechanics, are apt to regard it very calmly.

What, after all, is there so very wonderful about it?

Well, let us pour out a bucket-full of gasoline and placing it on the floor take in our hands four aluminum pistons weighing, say, a pound apiece. Problem: From some stuff like that limpid liquid in the bucket, through the medium of these four bits of bright metal, push 2 tons on wheels 500 miles in 5 hr.

What would you have said 10 years ago?

Don't Stampede

A NOTED English engineer recently voiced the opinion that the multi-cylinder movement which has gained such headway in this country will serve to develop the four and the six. In Europe the same conditions were experienced, only instead of eights and twelves, the six was the disturber. For several years Europe took up sixes enthusiastically, but now there are few made abroad. The six was more flexible and a better performer than the fours then built, but its coming stirred the designers of fours to greater activity, with the result that before long they were producing fours that were as good performers as the sixes. It took the six to waken them.

The public is not going to care whether it rides behind a four or an eight or a twenty-four so long as one performs as well as the other, so is not the main thing to bring the fours and sixes up to the standard of the eights and twelves? It will be easier for many engineers—and better perhaps for the dividends of the concerns they represent—to concentrate upon the making of better engines of types with which they are already familiar, than to strike out blindly into a field of design that is wholly new.

Two-Speed Rear Axle Suit

Washington Patent Attorney Sues Cadillac Dealer and Detroit Maker

WASHINGTON, D. C., June 26—Claiming damages in the sum of $100,000 Dempster M. Smith has filed suit in the District supreme court against the Cadillac Motor Car Co., Detroit, Mich., and the Cook & Stoddard Co., their agents here. Smith claims that he is the inventor of certain improvements for a motor car to change the speed gearing; that letters patent were issued to him by the patent office on February 7, 1911, and January 27, 1914, for these inventions. He further alleges that the Cadillac Co. and the Cook & Stoddard Co. have sold cars equipped with double direct-drive transmission gearing, which, he claims, is an infringement on his invention and that said gearing is in all respects similar to the gearing covered by the letters patent which he holds. He alleges that these cars have been exposed for sale since the issuance of the patents to him. Smith is a patent attorney and is associated with a patent law firm here.

—

Two Hudson Additions

DETROIT, MICH., June 28—The Hudson Motor Car Co. has contracted for two additions to its plant which will cost about $40,000. The first addition, a two-story building, 60 by 180 ft., will provide more room for the tooling and enameling departments. The second addition will consist of a three-story building, 60 by 100 ft., to the chassis and chassis painting departments.

—

Monarch Officials Resign

DETROIT, MICH., June 28—Three officials of the Monarch Motor Car Co., H. D. W. Mackaye, sales manager; W. R. Bamford, production manager, and A. A. Lehr, director of purchases, have severed their connection with the company and will enter into business for themselves.

—

Tire Co. to Start Near Denver

DENVER, COL., June 24—Colorado will soon have a modern tire factory, which will make tubes and casings especially adapted for the dry climate of the Rocky Mountain region. The plant is now being constructed and equipped at Arvada, 7 miles from Denver, by the Dry Climate Tire Mfg. Co., a Colorado corporation.

The first unit of the factory, a one-story building 75 by 200 feet, has been completed, and the machinery will be installed at once. The new concern expects to have tires ready for the market by July 1. The plant will be of modern construction throughout, equipped with the latest machinery, and expert tire builders will be brought in to take charge of the work.

Among the experienced tire men connected with the new enterprise is F. B. Clark, for several years with the B. F. Goodrich Co., who will be sales manager for the Dry Climate tire and who is well known to the trade throughout the ten or twelve states comprising the territory for which the new tires will be especially made. In the beginning, at least, the company expects to confine its trade to Colorado, Wyoming, Idaho, Utah, Arizona, New Mexico and part of Oklahoma, Texas, Kansas, Nebraska and South Dakota. This territory is now showing a yearly increase of about 10 per cent in the tire business.

The promoters of the new project have been experimenting for a year and a half to ascertain results of curing and vulcanizing tires in this climate, and claim that they will be able to sell their "acclimated" tires at standard prices and also furnish a 10 per cent. better guarantee.

The factory is being erected on a two-acre site donated by the people of Arvada, and the company has an option on an adjacent tract of five acres for expanding. The concern is incorporated for $200,000 and is financed entirely by Colorado capital.

There is no other tire factory in this vast territory between the Mississippi Valley and California.

The present size of the plant will have a capacity of 100 tubes and cases daily.

—

Fight Tar Nuisance

BOSTON, MASS., June 19—The first gun in the campaign to abolish the tar nuisance where the entire width of the highway is spread with it at one time took definite form here last week when the Automobile Legal Association sent out a request to newspapers and other organizations to fight the matter. The Bay State A. A. officials at once pledged their aid and the fight will be made throughout the State. The Highway Commission is to be asked to specify in all its contracts that but one side of the road shall be tarred at a time. In its request issued to-day the Automobile Legal Association states that the tarring of the entire width of the highway is not only responsible for damaging cars, but it also makes traveling dangerous, and increases the chances of accidents. And as the motorists pay more than $1,000,000 now in fees alone, exclusive of personal property taxes, it is felt that such nuisances should be abolished.

U. S. L. & Heat Co. Reorganized

Capital, $7,000,000—Headquarters at Niagara Falls—To Sell Old Co. July 1

ALBANY, N. Y., June 28—The United States Light & Heat Corporation of Niagara Falls, was incorporated to-day with a capital of $7,000,000. The company purposes to manufacture machinery and apparatus for the production of light, heat and power. The directors include A. Stanley Jones of 61 Broadway, New York; G. M. Walker and A. L. Fowle, 60 Broadway, New York.

The new company is to take over all the property and assets of the old United States Light & Heating Co., valued at approximately $2,500,000. The stockholders of the old company already have paid in assessments amounting to $472,000 and it is expected that before the new company begins business on July 1 at least $525,000 will have been received.

The sale of the property of the United States Light & Heating Co. is to take place at Niagara Falls on July 1 next and the stockholders' protective committee will bid for the property on that date, an amount probably slightly in excess of the $750,000 of debts of the old company.

It is the purpose of the management of the new company to eliminate the New York office, having its headquarters in Niagara Falls.

—

Chalmers Twin City Change

MINNEAPOLIS, MINN., June 29—The Chalmers Northwest Co. has been organized and incorporated, its capital stock being $50,000, of which $35,000 has been paid in. The new company has been appointed distributor for the Chalmers for practically the entire state of Minnesota and sixteen counties in Wisconsin. E. C. Thompson is president of the company; G. N. Michaud, vice-president; R. V. Hess, secretary-treasurer. Joseph Warren, formerly with the Chalmers Motor Co., Detroit, is sales manager for Minneapolis and G. N. Michaud is sales manager for the branch which will be operated in St. Paul.

—

Keeton Plant Sold

DETROIT, MICH., June 28—The Detroit Trust Co., receiver for the American Voiturette Co., which made the Car-Nation and Keeton cars, has sold the bankrupt concern's plant to Louis R. Grosslight, Detroit, and Isaac Gersen, Toledo, Ohio. The plant and factory property were appraised at $45,000 and it is said that this amount will be realized by the sale.

1916 Crow Price Reduced

Four-Cylinder Model Offered at $725 or $425 Lower—Complete Equipment

NEW YORK CITY, June 24—The Crow Motor Car Co., Elkhart, Ind., is offering a popular priced model for 1916 listing at $725 with full electrical equipment. This is a reduction of $425.

This new model known as the CE "30" is the largest four-cylinder Crow model that will be produced this year. The 3½ by 5 long stroke motor develops 34.9 hp., on brake test. The cylinders are cast en bloc with water jackets integral. The cylinders and head are cast separately. The head is removable. The connecting rods and crankshaft are drop-forged, 40 per cent carbon steel, double heat treated. The exhaust manifold is cast with an inner partition to prevent back pressure from one cylinder to another. The front crankshaft bearing is 1¾ in. diameter by 3¼ in. long and the rear is 1¾ in. by 3 15/16 in. long.

The axles are of the same design as previously used in Crow cars. The rear axle is full-floating with differential gears of nickel steel and is accessible for adjustments. The front axle is an I-beam section, drop-forged in one heating with no welding. The brakes have 11-in. drums and a 100 per cent braking surface. The front springs are full elliptic; rear springs are three-quarter elliptic and are slung under the axle with supports which swivel on the crucible steel axle housing.

Thermo-syphon cooling system is used. Lubrication is by means of the splash, constant level system; the level being maintained by a plunger pump. The crankcase is reinforced aluminum. It is possible to remove any connecting rods and pistons without disturbing the adjustment of the main bearings.

The equipment is complete including head-light dimmers, dash light, muffler cut-out, combination tail-light and license bracket, hinged robe-rail, tire and rim carrier in rear and extra rim.

The body is of streamline design. The built-in windshield is of the rain vision, full ventilating type. The steering column is placed at the left with gear shifting lever and emergency brake in center. The Disco starting, lighting and generating system is of the single-unit type with a 12-volt battery under the front seat. Stewart speedometer, dash light, electric switch and gasoline tank filler are located on the instrument board.

The wheels are 32 inches, equipped with 3½-in. tires and demountable rims.

Auburn Four and Six for 1916

NEW YORK CITY, June 25—The Auburn Automobile Co., Auburn, Ind., has announced a four and a six for 1916. The four will sell for $985 and the six for $1,550.

The four is a T-head motor, cast en bloc, 3⅞ by 5, unit power plant with three point suspension. Other features are cantilever springs, left drive and center control, electric lights and electric starter, one-man top, and fully equipped without extra cost. The wheelbase is 114 in. and the tread is standard.

The six seven-passenger touring car has a 3½ by 5 motor, center control, left drive, cantilever springs, electric lights and starter, one-man top and folding and disappearing extra seats. The wheelbase is 126 in.

1916 Moon Six at $1,475

NEW YORK CITY, June 26—The Moon Motor Car Co., St. Louis, Mo., has announced a seven-passenger six for 1916 selling at $1,475.

A 40 hp. 3½ by 5 Continental-Moon motor, with Delco starting, lighting and ignition system with a new switch, having an ammeter on the dash, is used. Other features are a Hotchkiss drive with underslung rear springs; a longer wheelbase, 125 in.; streamline body with disappearing seats entirely concealed when not in use; Stewart vacuum gasoline feed and speedometer; full-floating rear axle, crown fenders and one-man top.

A larger six, 50 hp., selling at $2250, will also be manufactured. This car embodies the same mechanical design as the 1915 model. The company will manufacture only these two sixes for 1916.

Ford Postpones Capital Increase

DETROIT, MICH., June 28—Rather than incorporate in another State than Michigan, the Ford Motor Co., it was said yesterday, will delay for two years the payment of its stock dividend and increase its capital from $2,000,000 to $50,000,000.

The directors recently decided to make the increase in capital stock and to pay a stock dividend of $48,000,000. It was discovered, however, that Michigan laws provide that no company incorporated under its statute shall have a capitalization in excess of $25,000,000. The company has therefore decided to wait until legislative action empowers it to carry out its proposed plan.

Overland Raises Wages

TOLEDO, OHIO., June 25—The Willys-Overland Co. has raised the wages of its 10,500 employees 5 per cent, effective July 15. The increase was voluntary, and will add $520,000 a year to the payroll.

Apperson Eight at $1,850

Two Sixes Also to Be Made by Kokomo Concern—Four Dropped

KOKOMA, IND., June 28—Apperson Bros. Automobile Co. of this city, has announced an eight-cylinder car for the 1916 season. It will be known as the eight-sixteen and will be made in a seven-passenger touring car and a four-passenger roadster. The wheelbase is 128 in. and the eight-cylinder motor is a V-type having 3⅛-in. bore and 5-in. stroke. The cylinders are cast in blocks of four and mounted on an angle of 90 deg. on the crankcase.

In addition to the eight, there will be two sixes. A large car known as the six-sixty, of 135-in. wheelbase and a T-head 4¼ by 5 block motor on which is carried a seven-passenger touring body and a smaller six known as the six-sixteen, which will have a five-passenger car mounted on 122-in. wheelbase and a seven-passenger touring and four-passenger roadster on 128-in. wheelbase. The motor in this car is an L-head 3½ by 5⅛ with the cylinders cast in a block.

Large Size, $2,350

The prices for the eight-cylinder cars are $1,850 for the larger six; $2,350 for the smaller six; $1,485 for the five-passenger car; $1,550 for the roadster and seven-passenger design. The four-cylinder model made for 1915 has been discontinued.

Chief interest centers around the eight-cylinder car as it marks the entrance of one of the older concerns in America in this new field. The car is fitted with a three-speed gearset, floating axle and full electric lighting and starting equipment. It is of distinctive appearance having a V-shaped radiator which is used in connection with a thermo-syphon system. The tires are 34 by 4 in. on demountable rims and gasoline is fed by means of a vacuum system.

Compression Band Clutch

The six-sixty also uses a three-speed gearset with floating axle and is fitted with the Apperson compression band clutch. Cooling on this car is by vein pump and the V-shaped radiator is also employed. The tires on this car are 37 by 4½. The oversize for the 36 by 4 wheel. On the smaller six, known as the six-sixteen, pump water circulation is also used, together with three-speed gearset and floating rear axle. The tires are 34 by 4 on demountable rims and the gasoline is fed by vacuum system. All the cars are fully equipped, the fittings being included in the purchase price.

Briggs-Detroiter Bankrupt

Liabilities $350,000, Assets $150,000—Detroit Trust Co. Appointed Receiver

DETROIT, MICH., June 28—Referee in bankruptcy Lee E. Joslyn, to-day adjudicated the Briggs-Detroiter Co., manufacturer of the Detroiter cars, bankrupt, Saturday, June 26, Judge Tuttle of the United States district court, appointed the Detroit Trust Co. receiver for the automobile manufacturing company. Since June 16 the trust company has acted as custodian for the automobile concern.

An inventory of the liabilities and assets of the concern is now being prepared by tht Detroit Trust Co. and will not be completed for several days, but it is estimated by officials of this company that the liabilities will total between $350,000 and $400,000 and the assets $150,000 or thereabouts.

The creditors' committee which has been trying to re-adjust the affairs of the company was composed of R. K. Davis, Penn Spring Works, chairman; Louis S. Smith, Griswold Motor & Body Co.; M. A. Monahan, Gemmer Mfg. Co.; M. Brooks, Kelsey Wheel Co., and Attorney Luman W. Goodenough. The Briggs-Detroiter Co. was organized in November, 1911, with a capital stock of $200,000.

Westinghouse Rebuilding Cleveland Plant

EAST PITTSBURGH, PA., June 24—The Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa., has obtained a permit to make extensive alterations in its Cleveland plant. It is stated that all wooden buildings will be replaced with modern fireproof structures. On completion of the new foundry the company plans the removal of the Pittsburgh foundry equipment to Cleveland.

Syndicate Buys 40,000 Shares of Stewart-Warner Common

NEW YORK CITY, June 28—A syndicate headed by White, Weld & Co. and Hornblower & Weeks, in which John Burnham & Co., Kissel, Kinnicutt & Co., and others are interested, has purchased from President J. K. Stewart of the Stewart-Warner Speedometer Corporation, 40,000 shares of his holdings of common stock in that concern. Mr. Stewart was the owner of considerably more than half of the $10,000,000 common stock and still remains the largest individual shareholder. He will continue as president, his contract to fill that office running until July 1, 1916.

The syndicate intends to resell the stock privately to investors and the syndicate agreement runs until Sept. 1.

To date the company has made about 150,000 horns and 80,000 vacuum tank gasoline feed systems. Net earnings of the company for the first quarter of 1915 increased approximately $185,000 over the corresponding period of 1914, and gross sales for the second quarter are estimated to be 25 per cent ahead of a year ago.

Picard to Distribute Connecticut-Ford Ignition System

NEW YORK, June 30—A. J. Picard & Co. has been appointed exclusive distributor by the Connecticut Telephone & Electric Co., Meriden, Conn., for a new ignition system for Ford cars which the latter company is just placing on the market. This is the standard Connecticut automatic ignition system with the necessary brackets and wiring adapting it for a Ford car. The system is designed for use on any Ford car which is equipped with a storage battery for lighting purposes. A feature is that only the switch appears on the dash, the coil being mounted on the engine close to the distributer.

Postal Service to Order 100 Trucks

WASHINGTON, D. C., June 29—*Special Telegram*—Within the next few days, the purchasing agent of the postal service will issue a call for bids for furnishing approximately 100 trucks for the city and rural delivery service.

The conditions to be presented in the proposals will be such as to make it possible for every manufacturer of trucks to enter the competition. The date of the opening of the bids in this city will be announced by the postoffice department later.

Continental After Boat Factory

MUSKEGON, MICH., June 26—The Continental Motor Manufacturing Co. is trying to secure for a period of about six months half of the shops of the Racine-Truscott Shell Lake Boat Co. and has taken up the matter with the receivers for that concern. Although more than 1600 men are now employed by the Continental company and large additions are in course of construction, more room is needed at once. If the shops are secured it will mean that the working force will be increased by 250 to 350 men at once.

$175,000 Addition for Packard

DETROIT, MICH., June 22—The Packard Motor Car Co. will erect a five-story factory addition, 395 by 60 ft., of reinforced concrete. It will cost $175,000.

Australia Requires Motor Trucks

Right-Side Drive Vehicles Are Desired—Dealers Want Sound Financial Makers

SYDNEY, AUSTRALIA, June 4—Motor truck business is going to be enormous in Australia, in fact, it would not be surprising if inside of a year the country would be taken by storm in the demand for trucks. Horse feed is to-day at a premium and of an inferior quality at that. Horses are getting scarce, due to the increased demands of the war. Everything points to a shortage of both vehicles and men and in the transportation of goods the solution seems to lie in the path of the motor truck.

Conditions in this country at the present time are prosperous, extraordinarily so, but it is difficult to see from what source such prosperity is going to continue. This country is one of enormous wealth and it is marvelous where money comes from, so it will not be surprising to see the trade hold up in spite of the war.

The jitney bus is arriving. Some operators are using ¾-ton trucks which have been fitted with special bus bodies. The jitney is going to command great attention as this country has great opportunities for motor passenger service.

In this country the motorists are glad to see that America is taking up the movement THE AUTOMOBILE advocated for years, namely, smaller high-speed engines as exploited in Europe. Over here, the big, low-speed American motor has been objectionable to buyers and it is only the price of American cars that has kept them in the lead. With the advent of the high-speed, smooth-running motor you can rest assured that American cars are going to come into public favor more than ever before. At the present time it looks as if eight- and twelve-cylinder cars will not be popular.

At present some of the leading dealers in Sydney and Melbourne are in the market for a good line of trucks ranging in capacity from ¾ to 4 or 5 tons. These dealers are particularly interested to get agencies from companies that are well backed financially and not likely to go out of business in a few years. It is necessary to have right-hand drive vehicles here, the left-hand drive is prohibited in some of the states of Australia and it is possible that this prohibition will extend throughout the entire Continent.

Rands Top to Add

DETROIT, MICH., June 24—The Rands Mfg. Co., top and specialty makers, will build a three-story factory addition to cost $20,000.

Dealers' Activity in Middle West

Many Changes in Dealers in Kansas Territory—Limit Dealers' Tag Use

KANSAS CITY, MO., June 30—There has been considerable change in many dealers throughout the Kansas territory during the present month. A. L. Ellwood has succeeded Capt. W. F. Siegmund as manager of the Kansas City branch of the Marmon company. This branch will have henceforth larger scope, and will be the distributing center for Kansas, western Missouri, Oklahoma, Nebraska, northern Texas and southern Iowa. Mr. Ellwood comes from St. Louis, where he was Western salesmanager of the Locomobile. Captain Siegmund resigned to become vice-president and general manager of the Automobile Sales & Service Co., in St. Joseph, Mo., which will handle Marmon, Maxwell, Hudson, Detroit Electric and the G. M. C. The Fifth St. Garage & Repair Co., 210-14 East Fifth Street, is extending its quarters and will have capacity for sixty cars in the garage department.

E. W. Arrasmith, formerly in charge of the retail department of the Oakland Motor Co., of Kansas City, has organized the Kansas City Oakland Automobile Co., which will have the retail business of the Oakland here. The Oakland Motor Co. will do only a wholesale business. The headquarters will continue as heretofore at 1521-23 McGee Street.

Kansas Dealers' Tags Restricted

TOPEKA, KAN., June 24—J. T. Botkin, Secretary of State, in sending out blank applications for motor license tags, has issued a general warning that in Kansas dealers' tags can be used only on demonstration machines, and their lending to customers of the dealers is a violation of law, and will be prosecuted.

Packard Missouri Co. Expands

ST. LOUIS, MO., June 26—It became known here recently that $175,000 was the price paid by the Packard Missouri Motor Co. to the Halsey Automobile Co., for the latter's four-story building here. W. J. Parrish, who recently bought out O. L. Halsey's interest in the company bearing his name, has moved from Kansas City to St. Louis and from the newly acquired building here, will direct the distribution of the Packard company's cars into Missouri, Kansas and Oklahoma.

Goodrich Expands Service in Joplin

JOPLIN, MO., June 25—The B. F. Goodrich Rubber Co. has established its third mechanical depot branch here, putting this city in the class for distribution purposes, with Birmingham, Ala., and Norfolk, Va. N. B. Finney, formerly of Denver, Col., will have charge of the sales. John W. Pratt was transferred from Buffalo, N. Y., to take command of the local branch. The Middle West and Southern States will be supplied from this branch.

Dodge Bros. Contest Income Tax

WASHINGTON, D. C., June 26—Counsel for John F. and Horace E. Dodge, of Dodge Bros., Detroit, Mich., yesterday filed a brief for argument before the United States Supreme Court, attacking the surtax on incomes of individuals under the Federal Income Tax law. This is the first attack to be made on the constitutionality of this law.

The case was begun to prevent the collector of internal revenue at Detroit from collecting a surtax on each of the Dodges of approximately $45,000 for the year 1913. The Federal district court in Michigan held the tax valid.

Three main reasons were assigned for claiming the surtax provision of the law is invalid. Stockholders in corporations, it is asserted, when computing their surtaxes, are subjected to liability for the gains and profits of the corporations which have not been divided or distributed. "To tax a stockholder on prospective dividends which he may never receive can only be properly characterized as so utterly absurd as to induce levity," the brief declares.

It is charged also that the provision vests in the Secretary of the Treasury an arbitrary power of determining, without a hearing, whether any corporation has accumulated a greater undivided surplus than is reasonable for the needs of the business. "How can he reach such a decision?" it is asked. "The law makes no provision to aid him."

A third reason is that the provision permits corporations to accumulate and withhold from surtax such part of their profits as may be reasonably necessary for the needs and purposes of their business, and does not accord such business privilege to individuals and partnerships. It is urged that corporations are thus favored by a "most invidious discrimination."

The brief urges that the sixteenth amendment to the constitution did not obliterate entirely the provisions of the constitution against "direct taxes," and that Congress can only tax income and not real or personal property. It is contended that Congress can make no distinctions as to the source of income.

New Studebaker Truck Manager

ST. LOUIS, MO., June 26—J. L. Bergs, formerly Illinois territory representative of the Studebaker company, has been placed in charge of the commercial car sales of the St. Louis branch of the Studebaker corporation.

Sioux City, Omaha and Tacoma Ready

Entries Full at Three Speedways—Omaha Ready for Inaugural Opening

CHICAGO, June 29—*Special Telegram*—The majority of the racing cars and drivers who participated in the 500-mile race on the new speedway here last Saturday have shipped their cars for Sioux City and Tacoma, where races will be held during the national holiday. The Sioux City 300-mile race which was started last year will be held on Saturday, July 3, on the 2-mile dirt speedway in that city. On the following Monday the opening of the 1.25-mile board speedway at Omaha, Neb., will take place with a 300-mile race. At Tacoma, Wash., three races will be held on Sunday and Monday, July 4 and 5, on the new 2-mile board speedway, which was opened last year as a dirt track and has since been boarded. Prizes amounting to $15,000 will be given at both Sioux City and Omaha.

Three of the drivers that competed at Chicago will pilot cars at Tacoma. They are Earl Cooper, Bob Burman and Billy Carlson. All three left for the Northwest Sunday morning.

Dario Resta, winner of the Chicago race, will be the headliner at both Sioux City and Omaha, while Burman, Cooper and Carlson will have to divide the glare of the spotlight with Barney Oldfield at Tacoma.

Sioux City Entries

The following twenty-two entries have been recived for the Sioux City race:

Peugeot, Resta; Maxwell, Rickenbacher; Maxwell, Orr; Duesenberg, Alley; Duesenberg, O'Donnell; Duesenberg, Haupt; Erwin Special, Grover Bergdoll; Erwin Special, driver unnamed; Duchesneau, Brown; Mais Special, Mais; Sebring, Joe Cooper; Emden, Grant Donaldson; Mulford Special, Ralph Mulford; Ogren, Chandler; National, Butler; Chalmers, Wetmore; White, Shrunk; O'Connell Special, driver unnamed; Anderson Special, Scott; Berwyn Baby, Zucher; and Donaldson Special, Lou Donaldson.

The prediction is common that Rickenbacher's average of last year 78.6 miles an hour will be shattered. The track, hard packed and oiled, is much faster than in 1914, and cars have shown greater velocity this season than they did last.

Porter-Knight Withdraws

The three Knight-motored Porter Knight cars entered at Omaha were withdrawn by Finley R. Porter.

Analysis of Automobile Industry in Great Britain During War

Factories Busy on Aeroplane Motors— Private Car Output One-Third Normal— Used-Car Values Advanced 7 Per Cent

LONDON, June 17—It is not easy to write on the present position of affairs in the automobile world here, partly because the picture is as everchanging as the chameleon, and partly because, since the government order which has led to the taking over of some of the most important factories, those works have been completely shut, barred and sealed to all outside enquiries. This order came into force March 15, chiefly as the result of labor troubles. Strikes and this order have introduced the public to the word output, which, formerly the keynote of the manufacturing engineer, has now become the shibboleth of the man in the street. Two main factors have affected the motor output of this country: 1. shortage of labor; and 2, strikes.

In comparing British automobile output before and during the war one can only generalize, for there are all sorts of conditions to throw out any accurate computation. Many factories, as, for instance, the old Argyll works, which have been bought by Armstrongs, are turned on to ammunition making. Others, like Wolseley, Daimler, Sunbeam and Austins are making aeroplane engines, some of them of the eight-cylinder V-pattern, others of the Gnome rotating-cylinder type, others with twelve cylinders 90 x 150 mm. arranged V-pattern, these last being intended for sea planes.

Again, private car manufacture is being ousted by the call for trucks. Some firms, like the Star, that did comparatively little in this line have been turning out a lot, some I believe for Russia (Austins have also done a vast amount for the Russian Government), while others like the Daimler or the Wolseley, that made commercials in considerable numbers, are turning them out in far greater numbers. And the demand does not stop with the truck: for instance, one big midland firm is making big sleeve-valve engines for gun tractors. Then again another firm is engaged in armoring and fitting up a lot of Pierce-Arrow commercial chassis for use with armored cars and to carry a gun. Again, to give another example of how difficult it is to obtain a basis for estimating the output of the present, let me mention the case of a commercial truck making firm with an output of twelve or fourteen trucks a week in normal peace time: at present they are not turning out a single car, but are devoting themselves to the making of spare parts.

This demand for spare parts assumes considerable dimensions. For instance, for every twenty chassis the British War Office requires one extra steering gear and housing; for every ten chassis one water pump, one set of holding-down dogs for tappet guides, one gasoline tank, and one set of selector mechanism have to be supplied; for every five chassis one complete set of connecting rods with bolts, one set of radiator tubes, one set of gearbox ball bearings and thrust washers. Every three chassis have a complete spare radiator; every two chassis a set of big end and crankshaft bearings. Each single chassis has its spare set of pistons with wrist pins and rings, and two sets of liners for shoes for the foot brake.

Output, 35,000

The normal British output of makers of private cars, light vans on pneumatic tires, in fact, all vehicles having the characteristics of private car chassis, may be put at not more than 30,000 to 35,000. It is impossible to give a closer estimate as no figures are available. Whether commandeered lock, stock, and barrel, or left alone, the total output of private cars from British factories at the present time scarcely exceeds one-third the normal for this time of the year, the rest of the industry's energy being devoted to war material, either as contractors or sub-contractors. On the known weekly output of all the leading commercial automobile works in Great Britain the normal annual output of heavier vehicles may be placed at 10,000 to 12,000, and careful enquiries point quite decidedly to the fact that some 40 per cent. more stuff is now being turned out than before the war.

The output of the big private car-making works, like those of the Daimler, Sunbeam, Lanchester, and Rolls-Royce, have been practically taken over by the government, while even considerable firms that are not requisitioned, such as the Rover and Swift or Standard companies, at the time of writing are devoting somewhere about two-thirds of their work to government output, as sub-contractors: one is making gearboxes for a lorry firm; another back axles; a third certain engine parts; while at least one is doing some ammunition work.

Talking of ammunition work, the Vauxhall company has put up an ammunition factory quite separate from its motor works, a performance that will be regarded as quite a feat of construction at any other time than the present.

In private car output the firms most affected have been those making cars too small to do what the government wants. The smallest cars taken have been the 16-horsepower Sunbeam, four-cylinders, 80 x 150 mm., and the 16-horsepower Vauxhall, 90 x 120 mm. In both cases these have been mainly used for ambulance work, though some are employed as staff cars. For most of the staff work something bigger is wanted, like the 25-horsepower Vauxhall, 95 x 140 mm., or the 20-horsepower Daimler, 90 x 130 mm.

Incidentally, no car with less than four speeds has been officially bought, though, of course, odd purchases of all kinds of cars have been made under individual pressure of circumstances. If we except an experimental order for sixty light cars to be used as two-seaters for some purposes not yet known, no order has been given in cold blood for anything smaller than the Sunbeam.

The 20-horsepower Daimlers, already mentioned, are being turned out, some as complete open cars, some as sort of light vans to carry 1120 lb. of material or men, for which there is seating accommodation. Though the Vauxhall people have supplied 16 horsepower they are at present devoting themselves wholly and solely to their 25-horsepower cars, 95 by 140 mm., and they, Wolseley and Daimler, are supplying some big cars for staff purposes; in some cases the staff cars have their seats so arranged that the car interior can be used as a sleeping apartment for staff officers. The royal naval air service is absorbing a goodly number of cars, mostly Talbots, and though a good few such cars as Vauxhalls are used a lot of these are armored. Rolls-Royce, Lanchester and Austin, among others, are turning out staff cars and armored cars, the latter in no small measure for Russian requirements. Humbers are making field kitchens, which is an engineer's rather than a body maker's job. Arrol Johnson has for a long time past been making such parts as maxim gun tripods, and Napiers are on gun parts, etc.

All 3 and 4-Tonners Commandeered

Further, practically all the output of 3 and 4-ton trucks throughout the country has been commandeered, for be it realized that the 3-ton subvention type of the British army to all intents and purposes is a 4-tonner for civilian work, while their 3,360-lb. class is capable of taking anywhere from 2 to 2½ tons. Indeed, many are building in no other sizes. Some few 5-tonners are being taken, but not many: they are too un-

wieldy, except for special purposes. The tendency, indeed, points rather to the absorption in the future of smaller types, such as 2-tonners.

But though demand exceeds the labor supply for every firm of any effectiveness in the country manufacturers are not without troubles. It is true that, selling only to government, they can reduce their selling costs, but labor dearth is having its effect, and the rise of price in material is feeding on its own growth. Yet in spite of this, automobile makers are being paid less by the government than they would be by their agents.

But with the substitution of many public buyers for a single government as customer dealing direct with the manufacturers, the dealer is having a very bad time. A good few of the smaller and less intelligent have already gone under, those who survive adapting themselves to present-day requirements. For instance, they are devoting more attention to the commercial vehicle, and some, realizing the unsatisfactory state of railway transport, for the railways have been taken over by the government, are contracting for motor transport. In some few instances, however, which have come to my notice they are handicapped with a lack of proper knowledge of working costs.

Price Question on Second-Hand Cars

The question of the second-hand vehicle is likely to assume proportions. Quite recently there was a trade debate on the possibility of fixing a minimum price for second-hand cars, though it was generally thought to be impracticable to saddle the public with restrictions. It is a question, however, whether the same impracticability applies to battle-worn cars after the war. The whole matter will lie in the hands of the government, and though not generally expressed it is felt that the government should treat with every consideration the interests of the automobile trade to whose help they owe so much in this campaign.

So far the most practicable suggestion is one advocating that since each manufacturer's reputation is dependent on the performance of his vehicles, each manufacturer should be appointed by the military authorities as agent for the sale of his own second-hand war vehicles. These would be turned over to him on the understanding that they would not be sold below a certain minimum price, and that no vehicle would be sent out without the manufacturer's guarantee of its sound condition.

Dearth of New Cars

Even now the second-hand car problem is with us, but at present rather from the opposite point of view, demand exceeding supply. It is said that the dearth of new cars, especially in the larger sizes, is sending up the price of the second-handers. The other day a man in the trade said he had advanced 17½ per cent. Comparison of the prices certainly shows a general rise, though in some cases, as, for example, Fords, 1915 second-hand prices strangely enough appear down on those of last year. From a careful comparison of prices of similar second-hand cars of this and last year 7 1-2 per cent advance for 1915 appears much the more correct general figure. We have heard a good deal about a coming car famine, but with the general public going very carefully in financial matters, and some 2,000,000 additional men away on military duty, this possibility is likely to be overrated.

N. A. C. C. Cross-Licensing Patent Plans Now Almost Completed

Sixty-Nine Companies Already Have Agreed to It—These Control Over 300 Patents—Rest of Ninety-Three Members Expected to Join in Agreement

NEW YORK, June 29—The cross-licensing plan recently formulated by the National Automobile Chamber of Commerce, whereby one automobile maker holding patents can enjoy reciprocal privileges with makers holding other patents, thereby avoiding needless patent litigation, has been practically assured success. To date sixty-nine companies of the ninety-three that are members of the N. A. C. C. have formally agreed to this cross-licensing plan, and six other companies have agreed to the cross-licensing principle but are awaiting action by their boards of directors. Other concerns have expressed approval of the plan and are awaiting action of their directors.

Action on this cross-licensing agreement was entirely voluntary on the part of any members and it was further provided that the plan would not be operative until sixty-one companies controlling in all 300 patents had executed the necessary document of agreement. This has now been more than accomplished.

Practically all members of the N. A. C. C. hold patents of one kind or another and this cross-licensing agreement is expected to bring about better business relationships, to reduce patent litigation, and also to leave the members free to expend their resources in developing scientific manufacturing, selling and advertising, rather than squandering them in patent law suits. It was expected that with few exceptions all of the ninety-three members of the N. A. C. C. would eventually be pledged in this cross-licensing scheme.

Committee in Charge

The patents committee in charge of this work includes, Messrs. C. C. Hanch, Studebaker; W. H. VanDervoort, Moline; Windsor T. White, White; Wilfred C. Leland, Cadillac, and Howard E. Coffin, Hudson.

The plan of the cross-licensing agreement provides that each member give licenses under the patents he owns to all other members of the chamber, who do likewise. For example: A company may have only five or six patents, yet that company is certain, upon entering the agreement, to have reciprocal rights to not fewer than 300 patents owned by other members.

While each member may consider its patents of value and important, it could not but feel that they were of less importance than the patents owned by the balance of the industry. It is just that broad situation which has made possible the success of the plan.

The agreement covers an arrangement by which members are to exchange free licenses under all their motor vehicle patents, with the exception of design patents and certain patents on trucks, tractors, fire engines and ambulances, and with the further exception of basic patents of revolutionary character that may be developed within the member's own organization. Although a large number of patents in the chamber are of vital importance, the greatest trouble has arisen from patents of trivial character and minor importance, the evils of which are overcome by this agreement when it becomes operative, whereas there is still the same inducement as there always has been for real advancement in the art by the provision which excepts patents of revolutionary character.

The Agreement

In a brief issued by the N. A. C. C., the main points of the agreement are given as follows:

1—It is obviously for the interests of the manufacturing members of the Chamber to remove the possibility of patent litigation between them.

2—No matter how many patents any single member may own, it is certain that license rights under the aggregation of patents which will come under this agreement will be much more valu-

Gasoline Price War in Missouri

Reduced 10 Cents in 18 Months —Small Dealers Hit Hardest by S. O. Cuts

ST. LOUIS, MO., June 26—There is a gasoline price-cutting war on in St. Louis and surrounding territory, but in the opinion of the independent dealers it is only a sham battle between the Standard company and the Pierce Oil Corp. with the two-fold purpose of freezing out the small dealers and at the same time cornering the oil surplus.

In eighteen months the price of gasoline has been reduced by 1 cent cuts from 17½ cents a gallon to 7 9/10 cents a gallon. In each case the cut was first announced by the Standard Oil Co. This usually was followed on the next day by the Pierce company's announcement of a similar cut. The independents by necessity then met the new price—only to be forced to meet another cut of 1 cent a few months later.

At present the refined product is sold to the consumer here for 8 9/10 cents a gallon in lots of from 10 to 100 gallons. In 100-gallon lots—as it is bought by many automobile owners—gasoline is sold here now for 7 9/10 cents. Quantity prices were introduced here only a few months ago.

The following view of the so-called war, which is characteristic of local independent dealers, is given by F. C. Bretsnyder of the Bell Oil Co., an officer in the national organization of independents:

"During the last two years there has been an over-production of crude oil. This gave the Standard Oil Co. an excuse for cutting the price of the crude product gradually from $1.05 a barrel to 40 cents a barrel, Pennsylvania crude from $2.50 to $1.35 a barrel.

"The time came when with each Standard Oil cut in the price of gasoline one or more small dealers went out of business. Even now the larger independent dealers are compelled to turn their business to other lines such as lubricating oils in order to survive the price-cutting sham battle between the Standard and Pierce companies.

"When these two companies get gasoline down to the price at which it will suit them to buy they will corner all the surplus; then the price will begin to go up again. The independents see through this scheme, but are powerless to stop it as the Standard Oil's operations are wholly within the law. Of course the independents are organizing more and more to protect themselves and I think we have found ways of holding out until the price-cutting war is over."

Mr. Bretsnyder denied, however, that the independents are co-operating to facilitate the merchandising of their wares, except in so far as the export committees and organizations are concerned.

Market Prices Steady

NEW YORK CITY, June 29—Changes this week in the market prices were exceptionally few. Changes, if any, were higher. Lead went up 50 cents per 100 lb., while electrolytic and Lake coppers went up ¼ and 1 cent, respectively. Fine Up-River Para went down ½ cent. The rest of the products remained throughout the week unchanged.

The tin market was easy with activity in London. The demand for aluminum is limited and the market is nominal. There was a fair demand for lead.

The rubber market was firm with no new developments. The trade in various kinds of manufactured rubber continues good.

The oils and lubricants markets were steady throughout the week.

Four-Wheel Drive Adds

CLINTONVILLE, WIS., June 25—The Four Wheel Drive Co. has broken ground for a large addition to the present plant. The new building will be built adjoining the present factory and will cover an area 100 by 185 ft. The structure will correspond in construction to the present buildings, will be brick and steel, and fireproof. It will be used for assembly poses.

At the same time additional machine shop facilities will be added covering a like space.

This addition to the present plant is the fourth building erected in the last 3 years. At the present time the company is turning out approximately seventy-five 3- and 5-ton chassis a month. The enlarged factory and improved facilities will permit an output of 100 to 125 trucks a month.

A day and night shift has been working several months.

Duplex Truck to Add

CHARLOTTE, MICH., June 24—The Duplex Power Car Co., which for some time has contemplated increasing its capital stock from $100,000 to $200,000, will place only about $25,000 of the stock upon the market, the remainder having been subscribed for. The concern intends to enlarge its plant and add machinery.

Chase 117 per Cent. Gain

SYRACUSE, N. Y., June 21—A financial report covering the affairs of the Chase Motor Truck Co., of this city, for the first 5 months of the present year shows an increase in its truck business of 117 per cent. as compared with the same months a year ago.

$175,000 to Lozier Creditors

DETROIT, MICH., June 28—Within a few days the Detroit Trust Co. will pay a second dividend of 5 per cent, amounting to about $175,000, to the creditors of the old Lozier Motor Co. About two months ago the first payment of a 5 per cent dividend was made.

Durant Takes on 'Frisco Chevrolet

SAN FRANCISCO, CAL., June 26—Norman DeVaux and R. C. Durant have formed the Chevrolet Motor Co. of California and will distribute that car throughout the Pacific Coast. Durant, who is the son of W. C. Durant of the Chevrolet Motor Co., will make his headquarters at 1212 S. Olive Street, Los Angeles, and will have charge of he company's Southern business. DeVaux will make his headquarters at 1622 Van Ness Avenue, this city, and will manage the Northern business.

Mohawk Motor Truck Co. Incorporated

RAVENNA, OHIO, June 24—The Mohawk Motor Truck Co., Ravenna, Ohio, has been incorporated under the laws of Ohio, with a capital of $25,000, for the purpose of manufacturing motor trucks. The new corporation will take over the plant and personal property of the Ravenna Motor Truck Co., which has been

in business for some time. At a meeting held recently officers and stockholders decided to reorganize and to change the name of the concern.

A statement given out by the officers of the company stated that the plant would be operated 24 hours a day in the future.

The incorporators of the new concern are S. C. Dougherty, E. E. Jones, E. W. Chapman, Herman Hill and W. K. Dougherty.

Reo Athletic Assn. Formed

LANSING, MICH., June 24—The Reo Motor Car Co. has taken over and is now managing the Reo Athletic Association, J. M. Amiss being in charge. There is to be no membership arrangement nor annual fees, every Reo employee being entitled to the privileges of the association building and grounds. The rooms will be reserved to Reo employees and their families. Three double tennis courts are now being prepared and tennis and other athletic tournaments will be held during the summer.

Mutual Electric Moves to Detroit

DETROIT, MICH., June 23—The Mutual Electric & Machine Co., Wheeling, W. Va., has leased the building formerly occupied by the Detroit Electric Starter Co., Fort Street, West, and Fourth Street, and will move practically all of its plant here. While the concern's principal business is that of making switchboards and switches, it also makes materials used in the making of self-starters. The officials who will locate here are General Manager H. J. L. Frank, Sales Manager L. H. Frank, Chief Engineer F. A. Hagan and Consulting Engineer G. H. Morse.

Security Prices Normal

Break in U. S. Rubber Due to Rumors on Common Dividend Action

NEW YORK CITY, June 28—Security quotations last week held strong with few changes. Tire issues again featured the market with Firestone and U. S. Rubber in the fore. Firestone common showed a 13 point gain and a new high mark, 503, while U. S. Rubber went down 13 points, the break occurring on acount of rumors that the dividend on the common might not only be reduced but passed altogether, so as to give the company an opportunity to accumulate the large supply of working capital needed in connection with the development of great activity in the business.

Studebaker common during the course of the week made a new high mark, 80. Froh the break that followed the declaration of the 5 per cent dividend, there has been a 20 point rally. It is expected that the next payment will be at the rate of 6 per cent per annum. The preferred, which went off five points last month, is now back to about its previous high.

Most of the stocks picked up on Saturday and a few of them showed substantial gains at the close. Goodrich common and preferred, ½ and 1 points, respectively; Maxwell common went up 4 points; Goodyear common rose 2 points; and Reo Truck closed with a ⅝-point gain.

Walpole Stockholders Files Petition

BOSTON, MASS., June 28—The Walpole Tire & Rubber Co. case, which has been before the United States district court for nearly two years, took a new turn today, when M. G. Sollers, one of the preferred stockholders, filed a petition asking permission to intervene in the case for the purpose of taking appeals from decrees of the court ordering the sale.

M. and S. Differential for Fords

KANSAS CITY, MO., June 24—The M. & S. Gear Co., this city, are announcing that they are now in a position to make deliveries on their differential for Ford cars. The feature of the differential is that by the use of spiral gearing the power is equally applied to both wheels under all conditions. The gear is perfectly interchangeable with the bevel-gear type on the Ford at the present time and sells for but a trifle more than the Ford outfit.

Accessory Jobbers Meet July 21

CHICAGO, ILL., June 28—The National Association of Automobile Accessory Jobbers will hold its next meeting in this city July 21. Present indications are that a good attendance will mark this first meeting to start the organization of the association. Suite 1813 to 18, City Hall Square Building, has been selected as headquarters.

Goodyear Continues Refund Offer

AKRON, O., June 26—The Goodyear Tire & Rubber Co. announces a continuance through July, August and September of the offer to refund the entire purchase price if Goodyear S-V tires fail to prove superior to competing makes.

Goodrich Truck Tire Policy

Favors Small Singles to Duals—Large Duals Over Too Large Singles

AKRON, OHIO, June 29—A new step in the policy of the Goodrich Tire Co., of this city has been suggested by S. V. Norton, sales manager, for the truck tire department in which the company recommends the use of 5- and 6-inch single solid tires in preference to 3- and 3½-in. duals; but where singles are larger than 7 in., it is more desirable to use 4-, 5- and 6-in. duals as the conditions demand.

"Momentary overloading of solid truck tires," says Mr. Norton, "which ruptures the rubber by displacing it beyond the limits of its ability to recuperate, is the cause for more tire failures than probably any other factor.

"Momentary overloading means excessive strain or shock on the tire at certain points, due to the tire being forced to bear in one way or another more load for an instant than it is intended to support. This may be due to road inequalities, or other conditions. The result is the normal displacement and the creation of undue internal friction and heating which is not quickly radiated, so that the tire is damaged beyond repair.

Injuries to Duals

"In the smaller dual sizes those made up of less than 4-inch units neither tire is itself large enough to withstand these momentary loads, such as when one of the singles comprising the dual set, takes the entire load and the other is not touching the ground. A modification of these conditions happens on crowned roads where the curve of the surface places more load on the inner tire than the outer. The net result of this condition in which the load is alternately shifted from one to the other is a permanent rupture."

Evils of Large Tires

Mr. Norton further believes that the best results come from a happy medium and consequently for single tires larger than 7-inch sizes are used, the displacement on tires with a load takes place in such direction that it causes undue internal friction and the generation of heat which is not quickly radiated when the tire section is too large.

Many advantages are advanced for the use of 5- and 6-in. singles in preference to 3- and 3½-in. duals, some of which are as follows: One, saving in tire cost. Two, saving in wheel cost, due to narrower felloe, narrower felloe band, and other changes in wheel design. Three, saving in unsprung weight of wheel, tire and metal equipment. Four, saving in applying one tire to the wheel as applying two. Five, larger tire units will better absorb uneven road surfaces, and better compensate for excessive road crown thereby keeping the whole tire always in use rather than alternately one tire and the other as is the case with small duals, neither of which is large enough to bear the strain alone. Six, more readily fitted with non-skid chains. Seven, better trackage of rear wheels with front wheels. Eight, greater height of rubber tread, and consequently more cushion and increased life in tires, greater than 3 in., which are ¼ in. lower than regular sections of greater width. Nine, less leverage strain on the axle and bearings, due to the decreased width of wheel tread.

Mr. Norton believes that the schedule of tire ratings now in use which rates duals higher than the equivalent singles is open to criticisms and this rating may be altered in the near future. He belies that dual tires cannot possibly have a greater carrying capacity than twice that of a single tire of which it is composed, and hence the error in the existing ratings.

Davis J. I. Case Mechanical Engineer

MILWAUKEE, WIS., June 24—R. E. Davis, instructor in automobile and gas engine practice in the Milwaukee continuation school, Milwaukee, Wis., will retire July 1 to become mechanical engineer in the staff of the J. I. Case T. M. Co., Racine, Wis. Mr. Davis was formerly associated with Packard, Marmon, F. A. L. and Midland, and in 1913 took charge of the short course in the care and operation of automobiles instituted by the Iowa State College. In the fall of 1914 he came to Milwaukee to take charge of the motor course in the continuation schools. In his new position he will be the point of contact between the engineering department and the service, sales, advertising and publicity departments. He is to be succeeded at Milwaukee by H. L. Connell, formerly of Detroit, and well known member of the S. A. E., who came to Milwaukee last February to supervise the short course in motor car practice in the continuation school.

Saxon Drive-Away Day July 15

DETROIT, MICH., June 28—The Saxon Motor Co. has promoted a drive-away day for dealers to be held July 15. Saxon sixes exclusively will be driven away. To make the event more interesting a silver loving cup will be given to the dealer who in driving home makes at least 100 miles and consumes the smallest amount of gasoline and oil.

Tire Lessons from Chicago Race

Tires Destroyed at Over 100 M.P.H.—Board Track Better than Brick

By John F. Palmer

CHICAGO, ILL., June 26—An interesting side light on the long string of records that went to smash at the running of the Chicago speedway to-day is the bearing a wood surface appears to have on tire wear and practice.

As at Indianapolis all of the first ten cars to finish used cord tires and a comparative analysis of performance under the differing conditions obtaining should be interesting and possibly instructive.

First: Weather conditions were much the same, race day being cloudy and cool and preceded by much rain in both instances. Second: The cars contesting at Chicago ran true to the form shown at Indianapolis, Rickenbacker's Maxwell being the one exception. The practice and tuning up made possible by the time interval between the two races, enabled the Maxwell to justify the hopes had of it and stamping its design in the front rank of race car engineers. Third: Except change of carbureters in a few instances, equipment was identical.

What then made possible the phenomenal jump in average speed at Chicago over Indianapolis from 89.84 to 97.58 m.p.h.?

In my opinion the two chief factors were surface and banking, wood laid lengthwise of the track offering less rattling resistance and the minimum of vibration due to the longitudinal disposition of the joints, this contributing also a measurable resistance to skidding on the turns while the banking carried to an angle correcting side slip up to 90 m.p.h. contributed not only greater safety but automatically increasing traction by adding the enormous pressure of centrifugal force to the weight of car approximately at right angles to the axis of wheel rotation. This turned a force, that at Indianapolis made for danger skidding and tire wear, into added power efficiency that lessened slips.

100 M.P.H. Destruction

Curiously enough tire failure only began when the speed approached 100 m.p.h., when tires were literally torn in two by the complicated stresses introduced by taking turns at a speed higher than the track was designed for in combination with heavier tractive duty made possible by the high banking.

The foregoing is not offered as my final judgment but as an interesting line

Packard Stars at Uniontown

Breaks All Previous Records on 3-Mile Hill, Making It in 3:27 2/5

UNIONTOWN, PA., June 24—All previous records were broken at to-day's Uniontown hillclimb, when a Packard, driven by Charles Johnson, president of the local automobile association, traveled up the mountain side, a distance of 3 miles, in 3:27 2/5. The average grade for the course runs 7.754 per cent. The annual hill climb is held under the direction of the Uniontown Motoring Association.

A Chalmers, driven by A. E. Walden, won in the Class E, Non-Stock race, this being open to Class C cars with a piston displacement of 230 cu. in. and under. His time for the climb was 3:50.

Ralph De Palma participated in both races but failed to come in better than fifth in any of them. In the Class D, Non-Stock Free-for-All event, won by Johnson, he finished sixth in his Mercedes Special, his time being 3:55 2/5. In this event his magneto broke down, and his going was somewhat slowed down at times when the crowd stood too near the course.

The attendance was about 30,000.

Lessons from Chicago Race

(*Continued from page* 42)

of reasoning that to me seems to offer at least one possible explanation of the proved superiority in speed possibility of the wood over the brick surface.

Again: There is a doubt of the superiority of the sand paper surface of brick over the wood purely from a traction standpoint. The wood, however, undeniably conserves tire treads up to 90 m.p.h., as is evidenced by the performance of the slower cars, notably Grant's Sunbeam, though in his case there was a contributing element in the smoother flow of power and lighter impulses of his six-cylinder motor; and if banking is such a factor as it seems, the only limit to speed possibility and tire dependability is scientific banking that will reduce the tire strains to the comparatively simple ones, of power transmission and air pressure.

I can see large possibility of better coordination of track and tire design to the end that pure speed may reach its highest development and shall welcome further experience along this line.

170 Miles Per Tire

Chicago Speedway Eclipses Indianapolis Where 100 Miles Per Tire Was Average

CHICAGO, ILL., June 26—To-day's inaugural of the new Chicago speedway served to prove among the many questions which were subject of speculation, the fact that the 2-mile board track here is considerably easier on tires than is the Indianapolis speedway. This may be shown by the fact that on the twelve cars which finished to-day's race only forty-one new tires were required, as against forty-four new tires taken on by the eleven cars which finished the Hoosier classic. This means that in the 6000 miles covered by the finishers to-day it took one new tire for each 146 miles, whereas at Indianapolis the 5500 miles took a new tire for each 100 miles; that is, the tires ran 46 per cent further on the board oval than they did on the brick.

Forty-nine Tires Used

Forty-nine tires in all were used in the 8370 miles of running of the twenty-four cars in to-day's race. This is an average for the total number of starters of 170 miles per tire. The finishers in to-day's race used just over three new tires per car, whereas at Indianapolis they took four tires per car.

To-day's event was a complete victory for Silvertown cords, as the record for tire mileage in racing made by the Goodrich company with its cord tires at Indianapolis was shattered to-day when the same make of tires made a showing even better than was expected on the basis of the Indianapolis performance.

Grant Made No Changes

The palm must be handed to Grant and his six-cylinder Sunbeam on tire performance, for Grant not only did not change a tire, but made no stop for any reason whatsoever during the race. His feat, however, was duplicated by three other cars, so far as tire consumption was concerned, Alley in the Duesenberg, Babcock in the Peugeot and Cooper in the Sebring, all running the entire 500 miles without a tire change.

—

FALL SHOW ANNOUNCEMENTS

COLUMBUS, OHIO, June 28—Plans are progressing for the fall automobile show to be held by the Columbus Automobile Show Co., at the Ohio State Fair, August 30 to September 3. The show will be something out of the ordinary as one whole building has been leased by the company to display pleasure and commercial vehicles.

Goodrich Truck Tire Policy

Favors Small Singles to Duals—Large Duals Over Too Large Singles

AKRON, OHIO, June 29—A new step in the policy of the Goodrich Tire Co., of this city has been suggested by S. V. Norton, sales manager, for the truck tire department in which the company recommends the use of 5- and 6-inch single solid tires in preference to 3- and 3½-in. duals; but where singles are larger than 7 in., it is more desirable to use 4-, 5- and 6-in. duals as the conditions demand.

"Momentary overloading of solid truck tires," says Mr. Norton, "which ruptures the rubber by displacing it beyond the limits of its ability to recuperate, is the cause for more tire failures than probably any other factor.

"Momentary overloading means excessive strain or shock on the tire at certain points, due to the tire being forced to bear in one way or another more load for an instant than it is intended to support. This may be due to road inequalities, or other conditions. The result is the normal displacement and the creation of undue internal friction and heating which is not quickly radiated, so that the tire is damaged beyond repair.

Injuries to Duals

"In the smaller dual sizes those made up of less than 4-inch units neither tire is itself large enough to withstand these momentary loads, such as when one of the singles comprising the dual set, takes the entire load and the other is not touching the ground. A modification of these conditions happens on crowned roads where the curve of the surface places more load on the inner tire tha the outer. The net result of this co tion in which the load is alterna shifted from one to the other is manent rupture."

Evils of Large Tires

Mr. Norton further believ best results come from a h and consequently for sing than 7-inch sizes are us ment on tires with a l such direction that it ternal friction and heat which is not the tire section i

Many advant the use of 5- a erence to 3- and 3½ which are as follows: O tire cost. Two, saving in wheel c to narrower felloe, narrower felloe ban and other changes in wheel design. Three, saving in unsprung weight of wheel, tire and metal equipment. Four, saving in applying one tire to the wheel as applying two. Five, larger tire units will better absorb uneven road surfaces, and better compensate for excessive road crown thereby keeping the whole tire always in use rather than alternately one tire and the other as is the case with small duals, neither of which is large enough to bear the strain alone. Six, more readily fitted with non-skid chains. Seven, better trackage of rear wheels with front wheels. Eight, greater height of rubber tread, and consequently more cushion and increased life in tires, greater than 3 in., which are ¼ in. lower than regular sections of greater width. Nine, less leverage strain on t axle and bearings, due to the decrea width of wheel tread.

Mr. Norton believes that the sch of tire ratings now in use whic duals higher than the equivalen is open to criticisms and this r be altered in the near futu lies that dual tires cannot a greater carrying capac that of a single tire of posed, and hence the err ratings.

able than ... mber's individual patents.

3—It ... he industry together in a co... rit which is in keeping wi... cy of the times.

4—T... n little or no money made ... ts in the automobile industr... not likely that any money ... de out ... tents by litigati... the ... a patent lawsuit ... eive ... ch.

5—L... rofi... e from proper manufacturing and selling of cars, and not from exploitation of patents which generally do not represent more than the incidental development of motor cars, for which engineers are generally responsible whether they take out patents or not.

6—The main thing is to establish a substantial business with patents only as a protection against patent litigation. Primarily, it should be the object to get business, as patents are merely incidental to business.

7—While everyone hopes to obtain good patents in the future it is apparent that the patents taken out by any one member are not likely to be as valuable to him as rights under patents taken out by 75 to 100 other members.

8—Each member will be left free to display his originality along the line of design patents.

9—The agreement is largely limited to chassis units and parts; that is to say, units and parts that are common to either trucks or motor vehicles primarily adapted to private passenger use. No attempt has been made to include undeveloped and rapidly evolving things such as loading and unloading devices, fire apparatus, tractors, etc.

10—It is an entirely new and original plan in line with the co-operative movement of the day, which has obtained in the automobile industry with better results than in any other field.

11—Equitable provision has been made to exclude and leave free for special consideration any basic or revolutionary patent of great value which may hereafter be developed within the organization of any member, thus encouraging a continued advance in the art but eliminating those patents of minor importance that are many times used for harassing purposes.

12—The plan requires the signature of sixty-one members owning at least 300 patents coming within the terms of the agreement before it becomes operative, which insures protection of the most substantial order for each manufacturer before he is required to grant any rights under his own patents.

300-Mile Race for Chicago Oct. 9

CHICAGO, ILL., June 29—*Special Telegram*—Encouraged over the success attendant upon the inaugural race run over their new track Saturday the directors of the Chicago speedway now are contemplating the promotion of another contest in the fall and have requested Chairman Kennerdell of the A. A. A. contest board to reserve Oct. 9, for such an event. According to present plans the fall race will be 300 miles in length and $25,000 will be hung up in prize money.

Maxwell Laboratory at Chicago Track

CHICAGO, ILL., June 28—Believing that the Chicago speedway offers unexcelled advantages for testing automobiles Ray Harroun, the former racing driver, who is now head of the engineering department of the Maxwell Motor Co., Detroit, has made arrangements to establish an engineering laboratory at the local track and this summer will try out all the new models on the 2-mile board oval.

The building has a floor space of 40,000 sq. ft., all of which will be used for the showing of automobiles. Practically all of the space has been sold. It will be the first attempt to hold an automobile show on the State fair grounds.

—

LOS ANGELES, CAL., June 28—The Motor Car Dealers' Association of Los Angeles, has set the date for its fall show. This will be held during the week of September 18-25 in the Shrine Auditorium.

—

WESTERVILLE, OHIO, June 28—A large number of automobile agents of Columbus will give an automobile show at Westerville, Ohio, located about a dozen miles to the northeast, July 3. The show will be given in conjunction with the usual Fourth of July celebration and will be held on the principal street of the village. Spaces will be marked off on the paved streets and it is believed that about thirty different makes will be displayed. The idea is a new one and is being tried as an experiment.

—

Missouri Ad Law in Effect

ST. LOUIS, MO., June 24—Missouri's honest advertising law, created by the last General Assembly is effective. The law applies to every form of business and prohibits the mis-statement of fact in any form of advertising. Newspapers, posters, circulars and letters are specifically mentioned. Fines and jail penalties are provided for violations of the law.

—

Capital Stock Increased

DETROIT, MICH.—Consolidated Car Co., from $100,000 to $200,000.

—

DETROIT, MICH.—United States Auto Supply Co., from $5,000 to $75,000.

—

Four-Story Pierce Addition

BUFFALO, N. Y., June 26—The Pierce-Arrow Motor Car Co. will construct a new concrete flat-slab building on its site here at 1695 Elmwood Avenue. It will be four stories high, 410 ft. long, and 61 ft. wide.

—

Princess Leases Old Saxon Plant

DETROIT, MICH., June 28—The Princess Motor Car Co., organized in June, 1914, and located at 348 Clay Avenue, has leased the former plant of the Saxon Motor Co., Bellevue Avenue, and will move to it in a few days.

—

Gets New Era Contract

BATTLE CREEK, MICH., June 24—H. E. Petrie, who in addition to conducting the business of the Independent Garage, makes foot accelerators for Ford cars, has received an order for 70,000 from the New Era Spring & Specialty Co., of Detroit.

Standard Service Advocated

—

Service Managers Would Restrict Dealer's Parts—Different Truck and Car Service

DETROIT, MICH., June 29—*Special Telegram*—Ninety service managers and other representatives of fifty automobile and truck manufacturing concerns were in attendance at to-day's session of the service managers convention called here by the National Automobile Chamber of Commerce. Papers and discussions dealt mainly with the phases of the relation between the factory service department and the dealer, although there was much airing of views as to what the owner should expect in the way of service.

Co-operation Needed

In opening the two-day meeting, Alfred Reeves, general manager of the N. A. C. C., spoke for the same interchange of thought among the service men as is being practised by the heads of concerns in the organization.

Alvan Macauley, Packard vice-president and general manager, welcomed the delegates and said that service and service policy are the vital part of the business, and whether or not the makers get this down to a reasonable basis and hold it there will largely be a governing factor in their staying in business. That a standard policy is needed he is positive, and believes it necessary to survival.

Limiting Dealer's Parts

The consensus of opinion was that dealers' parts orders should be censored. That is, the amount ordered should be cut down if the manufacturer thinks such a large requisition not commensurate with the number of cars the dealer sells. It did not seem necessary for a dealer to carry parts for cars over two years old, the maker carrying these. A campaign of education seems advisable to get dealers to carry proper parts stocks.

It was quite generally conceded that there should be a standardized plan for handling parts accounts with dealers, but the methods are about as many as there are manufacturers.

Discussion of the subject of how the manufacturer can satisfy himself that the dealer who receives a credit installs the part in the customer's car without charge brought only the one answer, that, the customer should be notified of such credit to the dealer.

Owner's Service

What constitutes service to the owner was dealt with by Charles Gould, Maxwell service manager, who said that the four essentials to service are the carrying of repair parts, efficient repairs, supervised instruction and co-operation between dealer and owner as was to be expected, there was much difficulty in defining service, many definitions being proposed.

Committees will be appointed by Mr. Reeves to report on the various questions brought up by the papers and discussions, and strenuous effort will be made to get at the difficult matter of arriving at a standard service policy.

Cars and Trucks Differ

Morning and afternoon sessions Wednesday will close the meeting. Among the important subjects to be discussed are the reasons why there should be different service policies for passenger cars and trucks, Mr. Macauley reading a paper dealing with the question, Do Free Inspection and Adjustment Legally Extend the Manufacturer's Warranty. Pierre Schon, service manager General Motors Truck Co. will answer this.

—

N. A. C. C. Service Convention Opens

DETROIT, MICH., June 28—Forty-nine automobile manufacturers are represented at the 2-day service manager's convention promoted by the National Automobile Chamber of Commerce which opened its sessions this morning at the Hotel Statler. Eighty-four men prominent in the trade, including presidents, general managers, and sales and service managers are listed to take part in the discussions of the following important papers:

"Should there be a Standardized Plan for Handling Parts Accounts with Dealers?" by A. H. Ransen, manager of the Parts Order Department of the Studebaker Corp. "How Can Manufacturers Assist in Preventing Dealers Overstocking and being Obliged to Stock Obsolete Parts?" by C. W. Matheson, Director of Service, Dodge Bros. "Should Manufacturers Encourage General Repairshops by Selling Them Parts?" by J. A. Harris, Jr., Advertising Manager White Co. "How Can the Manufacturer Satisfy Himself that the Dealer Who Receives Credit Installs the Part in the Customer's Car Without Charge?" by E. T. Klee, Service Manager, Stutz Motor Car Co. "What Constitutes Service to the Owners?" by Charles Gould, Manager of Service, Maxwell Motor Co. "Why a Standard Service Policy Should be Adopted by All Members for the Benefit of the Car Builder," by A. B. Hansom, Manager Directing Service Division, Chalmers Motor Co. "Should the Dealer's Service Policy Go Farther than the Manufacturer's Warranty, and If So in What Respect?" for open discussion. "Should There be Different Service Policies for Passenger and Commercial Vehicles and Why?" by Alvan Macauley, vice-president, Packard Motor Car Co. "Do Free Inspection and Adjustment Legally Extend the Manufacturer's Warranty?" by Pierre Schon, Service Manager, General Motors Truck Co. "Advantages of Issuing Books of Coupons Entitling Owners to a Specified Amount of Repair Work Free."

Speedway Organization Incorporated

Speedway Assn. of America formed, Officers Elected—Will follow Baseball Ideas

CHICAGO, ILL., June 25—*Special Telegram*—Seven representatives of the Indianapolis, New York and Twin City speedways met here this afternoon, adjourned the meet at Hammond, Ind., a Chicago suburb, this evening and there effected the permanent organization of the Speedways Assn. of America by filing its corporation papers with the Secretary of State of the Hoosier commonwealth and electing officers and a board of managers.

The Speedway Assn. of America was born at Indianapolis just prior to this year's Hoosier classic. Representatives of the Indianapolis, Twin City, New York, Tacoma, Sioux City, Omaha and Chicago speedways were in attendance and a temporary organization was effected. Not until the association had been incorporated, however, was the organization in a position to start its campaign for the advancement of speedway racing and to take such important action was the purpose of to-day's session.

Edward E. Gates, chief attorney for the Federal baseball league and a resident of Indianapolis acted for the speedway associations drawing up the incorporation papers and filing them this morning. As soon as word was received that incorporation papers had been granted the seven representatives boarded a train for Hammond where the first stockholders meeting was held, the incorporation laws of Indiana stipulating that a company incorporated in that State must hold its first stockholders' meeting within the boundaries of that commonwealth. At the stockholders' meeting a constitution and by-laws were adopted and the following officers elected:

Temporary Board

President, Charles W. Sedwick, Indianapolis; vice-president, James C. Nichols, New York; secretary and treasurer, James A. Allison, Indianapolis; board of managers: Carl G. Fisher, Indianapolis; Jas. A. Allison, Indianapolis; F. H. Wheeler, Indianapolis; Charles W. Sedwick, Indianapolis; James C. Nichols, New York; Dr. C. E. Dutton, Minneapolis, and D. L. Wheeler, Minneapolis.

Although Chicago, Tacoma, Sioux City and Omaha were not represented at to-day's meeting officials of these four tracks agreed to become members of the association at the time of Indianapolis session and admission blanks have been sent them. As soon as they apply for admission the board of managers will be changed in order that these four tracks may have representation on the board.

The chief aim of the speedways association is that of mutual protection and co-operation and its motives are not antagonistic to drivers, as many have been led to believe.

Adopts Baseball Ideas

Each year it will adopt a schedule so that there will be no conflicts in dates, it also will be in a position to buy racing cars, a very scarce commodity at the present time, and will appoint a common representative to visit Europe and engage foreign drivers not for one race but for all contests promoted during the season. It will also classify speedways and put a stop to the practice of one promoter hanging up a larger purse than another in order to attract entries.

Objects of Organization

The paramount aims of the new organization are best expressed in the following excerpts from the speedways association by-laws:

1—The objects of the association are to govern, contract and manage speedways for speed contests or other expeditions.

2—To secure the co-operation and participation in the same.

3—To encourage and promote the development, use and sale of motor cars and to promote speed contests as a pastime in America and other countries, and to surround it with safeguards such as will insure public confidence in its integrity and methods and improve the standard of skill and sportsmanship of the participants therein.

4—To establish uniform rules and regulations for such speed contests and exhibitions and for the safety of the drivers and public.

5—To protect the property rights of those engaged without sacrificing the spirit of competition.

6—To promote the welfare of drivers, mechanicians and other participants by developing and perfecting them in their profession and aiding them in securing adequate compensation for expertness to protect and aid them to secure prizes.

7—To schedule dates and places for speed contests and exhibitions.

8—To foster and encourage the engaging of foreign entrants.

N. A. C. C. Cross-Licensing Plans

(*Continued from page* 39)

able than the member's individual patents.

3—It will cement the industry together in a co-operative spirit which is in keeping with the tendency of the times.

4—There has been little or no money made out of patents in the automobile industry, and it is not likely that any money can be made out of patents by litigating them, as the winner in a patent lawsuit seldom receives very much.

5—Legitimate profit should come from proper manufacturing and selling of cars, and not from exploitation of patents which generally do not represent more than the incidental development of motor cars, for which engineers are generally responsible whether they take out patents or not.

6—The main thing is to establish a substantial business with patents only as a protection against patent litigation. Primarily, it should be the object to get business, as patents are merely incidental to business.

7—While everyone hopes to obtain good patents in the future it is apparent that the patents taken out by any one member are not likely to be as valuable to him as rights under patents taken out by 75 to 100 other members.

8—Each member will be left free to display his originality along the line of design patents.

9—The agreement is largely limited to chassis units and parts; that is to say, units and parts that are common to either trucks or motor vehicles primarily adapted to private passenger use. No attempt has been made to include undeveloped and rapidly evolving things such as loading and unloading devices, fire apparatus, tractors, etc.

10—It is an entirely new and original plan in line with the co-operative movement of the day, which has obtained in the automobile industry with better results than in any other field.

11—Equitable provision has been made to exclude and leave free for special consideration any basic or revolutionary patent of great value which may hereafter be developed within the organization of any member, thus encouraging a continued advance in the art but eliminating those patents of minor importance that are many times used for harassing purposes.

12—The plan requires the signature of sixty-one members owning at least 300 patents coming within the terms of the agreement before it becomes operative, which insures protection of the most substantial order for each manufacturer before he is required to grant any rights under his own patents.

300-Mile Race for Chicago Oct. 9

CHICAGO, ILL., June 29—*Special Telegram*—Encouraged over the success attendant upon the inaugural race run over their new track Saturday the directors of the Chicago speedway now are contemplating the promotion of another contest in the fall and have requested Chairman Kennerdell of the A. A. A. contest board to reserve Oct. 9, for such an event. According to present plans the fall race will be 300 miles in length and $25,000 will be hung up in prize money.

Maxwell Laboratory at Chicago Track

CHICAGO, ILL., June 28—Believing that the Chicago speedway offers unexcelled advantages for testing automobiles Ray Harroun, the former racing driver, who is now head of the engineering department of the Maxwell Motor Co., Detroit, has made arrangements to establish an engineering laboratory at the local track and this summer will try out all the new models on the 2-mile board oval.

Race Motors Behave Marvelously

(*Continued from page 7*)

That the smoothness of the board track had the effect of lessening the shocks to which the cars were subjected is undeniable, but shocks have only a little influence in motor reliability, although they play a big part in the lasting power of springs and axles. Perhaps the roughness of the Indianapolis brick might be blamed for the loosening of the magneto platform on Van Raalte's Sunbeam, but that is about the only motor trouble in the former race which could fairly be blamed to shock.

Stupendous Reliability

It is quite difficult at first to realize what the speed of this Chicago race really means. The tabulation of reliability given above is but a pale outline of a few of the things which together make the most wonderful demonstration of motor efficiency which the world has ever seen. Perhaps the casual observer is liable to give weight to the fact that the first and second cars were both of foreign origin, but anyone knowing to how great an extent small things outside the chassis construction play their part in race winning, will pay but little regard to who won, rather will he look to the whole ten who made more than the 90 miles an hour.

Take the Stutz case, for example. Here we had evidence of a speed capability, in Wilcox's car, at least equal to and perhaps in excess of that possessed by either the Peugeot or the Sunbeam and the two Stutzes which finished within 12 minutes of the winner, both had many tire stops. Out of this time Anderson spent nearly 7 minutes more than Resta on tires alone, so his car was only a minute an hour slower than Resta's.

The first three cars to finish used the Zenith carbureter and Oilzum was used for lubrication on the cars finishing first, third, fifth, sixth, seventh, eighth, ninth and tenth, or eight out of the ten prize winners.

Stutz Tire Troubles

Why the Stutz men were so unfortunate with tires remains a mystery up to the present, for they were using the same sort as their luckier brethren and using them under the same conditions. Possibly the cars were held a little lower down on the banking than the Peugeot or the Sunbeam but even John Palmer, inventor of the cord tire, is not prepared with any explanation as to the remarkable difference in tire reliability as between one car and another.

Still, to keep to the motors, at Indianapolis, the general idea was that in putting up a speed which represented the limit of the track, the limit of the motor had been reached as well. Chicago proves this is wrong so the present idea is rather that the faster and easier course brings us back to tires and human endurance once more. Had the Chicago race been for 300 instead of 500 miles it would undoubtedly have been won at well over 100 miles an hour.

Sixteen-Valve Motors

In a mechanical review of the happenings of a race it is generally possible to take instances of trouble or failure and therefrom to extract lessons of engineering interest. Concerning this race so little happened, there was so little trouble, that the arising question is, "How can we get more speed?" instead of "How can we maintain the speed set as a standard?"

Chicago sets the mark of the multi-valve motor, it shows the sixteen-valve, four-cylinder motor developed to an equal pitch by America, France and England. Carburetion has been got in hand, ignition difficulties are overcome, and aluminum-alloy pistons have established their place.

But in this review let us not forget Harry Grant's old Sunbeam, for this is no modern creation, but an old warrior among the veterans of the race track with an L-head motor, two valves per cylinder and none of the aids to power developed within the last 2 years. Grant made his show largely by knowing how fast he could drive without trouble, by knowing that he had gas and oil enough for the whole journey and by having good reason to trust in his tires. Perhaps the smoother torque of the six cylinders had something to do with his tire reliability, without a shadow of doubt, his steady speed without 100-mile-an-hour bursts had a great deal more to do with it. Probably his speed is the limit of which the car is capable but it is considerably higher than the manufacturers ever expected of it in a race as long as 500 miles.

Turning now to those which fell by the way the Ogren suffered a mishap which might be due to faulty material or to insufficiently strong design. An extraordinary sort of failure altogether. It was the fracture of the casing which holds the bevel pinion and its bearings, thus allowing the pinion to fall out of mesh with the ring gear. In such a case nothing could possibly be attempted.

Too Much Oil

The old Mercer reported that no spark could be kept going and investigation made by the writer with the aid of the Bosch representatives disclosed the fact that the pistons, whether from too large a tolerance or some other cause were allowing so much oil to pass that the plugs became literally filled up with it. No plug on earth could have sparked under such a smothering cloud of lubricant.

Wilcox's Stutz after making very high speed for quite a long time suffered a broken piston.

Of the Dusenbergs one burned out a connecting rod bearing, probably through momentary failure of the lubrication, or a tiny bit of dirt in the oil channel perhaps. The other suffered a derangement of the clutch which made gear changing impossible.

Lastly, Limberg's old Sunbeam, a sister car to Harry Grant's, burned a bearing or broke a connecting-rod bolt, causing some complications inside which resulted in a punctured crankcase. Investigation by pulling down the motor was not made on the spot but it might reasonably be supposed that an instant's pause in the oil supply to some bearing or other was the primary cause.

Sunbeam Bearing Trouble

Of the cars which were left running after the first ten were in, Van Raalte had a broken connecting-rod and had been running for a couple of hours on three cylinders. The piston or the connecting-road bearing seized, the rod broke, hit the piston and so bent it that it jammed in the cylinder mouth and the bits of rod then dropped harmlessly into the crankcase. A hole was punched in the side of the case during these events, but this did not matter because of the lubrication system. On the Sunbeams oil is sucked back to the tank directly it gets through the bearings and drops to the base, so the latter never contains any oil.

The two Maxwells which failed to get among the prize winners appeared simply to be insufficiently fast.

CAUSES OF RETIREMENT IN LAST THREE SPEEDWAY RACES

Indianapolis, 1914	Indianapolis, 1915	Chicago, 1915
Broken cam	Broken connecting rod.	Broken bevel pinion housing.
Broken connecting rod.	Broken timing gear	Broken piston.
Broken rocker arm	Broken piston	Broken connecting rod.
Broken piston	Broken connecting rod.	Burned out bearing.
Broken valve & piston.	Broken wheel	Oil on plugs.
Broken connecting rod.	Broken piston	Faulty clutch.
Broken valve	Broken rear axle bearing	
Broken wheel	Loose flywheel	
Broken camshaft		
Broken camshaft	Smoking exhaust	
Broken connecting rod.	Cranked cylinder	
Broken ball bearing	Loose mud pan	
Broken frame		
Loosened cylinder		
Per cent retirement caused by broken parts, 93	Per cent. retirement caused by broken parts, 64	Per cent. retirement caused by broken parts, 50

Globe Tire Adds—The Globe Rubber Tire Co., Trenton, N. J., will build a two-story brick addition to its plant on Prospect street.

To Mfg. Tractors—J. C. Kerst is having plans made for factory to manufacture motor-driven farm machinery in Springfield, Ill.

Xenia Rubber Buys New Plant—The Xenia Rubber Co., Xenia, Ohio, has purchased the mills of the Belden elevator, 2½ miles from that city.

Portage Tire Purchases Plant—The Portage Rubber Co., Barberton, O., has purchased the old plant of the American Strawboard Co. and will erect buildings costing $300,000.

To Make Bumpers—The American Automatic Save-A-Life Co., Washington, D. C., will construct a plant at Cameron, W. Va., for the manufacture of automobile accessories and bumpers.

To Mfr. Diesel Engines—The Enkel Motor Co., Auburn, N. Y., will erect a plant for the manufacture of the Diesel type of automobile motor. C. H. Williams is vice-president and general manager.

Lenox May Move.—There has been some talk that the Lenox Motor Car Co. of Hyde Park, Mass., might move to Lowell, Mass., in the near future, if sufficient inducements were held out by the latter city.

To Manufacture Accessories—The Furgason Mfg. Co., Lansing, Mich., has acquired a new plant and will add the manufacture of automobile accessories to its present line of general machine shop products.

To Make Tires—The Essex Tire Construction Co. has been incorporated to manufacture automobile tires with a capital stock of $125,000. The plant will be in Irvington, N. J. The incorporators are W. Barth, F. H. Butterthworth and F. M. Mervin.

Gordon Rubber to Add—The Gordon Rubber Co., Canton, Ohio, has increased its capital stock from $300,000 to $600,000 and has under consideration the erection of new buildings that will double the capacity of its plant.

Newark Co. to Make Carbureters—The Mfg. & Sales Co. of the Float-Jet carbureter, has been incorporated to make carbureters in Newark, N. J. The capital is $300,000 and the incorporators are Siegfried Leschinger, C. F. Kraemer and J. M. Reilly, all of Newark.

Kellogg to Increase—The Kellogg Mfg. Co. plant has been working in day and night shifts for the last three months to keep up with orders for its engine-driven tire pumps. Recently the company added 15,000 feet of floor space. Plans are prepared for a larger plant and equipment to be ready as needed.

Tire Co. in Conn.—The Monarch Stitched Tire Co., formed recently in Maine, has purchased the Munroe-Eastman Co.'s plant at the border line between Newington and New Britain, Conn., in which the company will manufacture its product. The carcass of the tire is both stitched and cemented into the tread, and a guarantee of 6,000 miles without the adjustment clause will be given by the makers.

Falls Motor Adds—The Falls Motor Co., Sheboygan Falls, Wis., manufacturer of gasoline engines for automobiles, is about to erect a large new testing shop building. The new shop will be of brick and steel, 45 by 154 ft. in size, with concrete floors. The present testing shop is being equipped with machinery for motor construction. Overtime operations have been in effect for some months and the plant is employing more men than at any other time since its establishment.

Hoover Steel Starts Building—The Hoover Steel Ball Co., Ann Arbor, Mich., has broken ground for an additional new building, which will be 40 by 313 ft. and is to be filled with ball-making machinery. This will make the third new building which the company has erected since Sept. 1, last year, and comprising over 29,000 sq. ft. of floor space. This will allow the company to increase its payroll to between 500 and 600 employees. The company has contracted for approximately $65,000 worth of additional ball-making machinery.

$100,000 Addition for Fedders—The Fedders Mfg. Co., Buffalo, N. Y., will spend $100,000 on a new four-story addition to its plant. When the new place is finished the floor space of the plant will be doubled. The offices, which are now in one of the old buildings, will be moved there and the space that they occupy at the present time will be added to the factory. Besides housing the offices it will include the service department. The new building is one story higher than the other buildings which comprise the plant. Brick and steel are the principal materials being used in its construction.

The Automobile Calendar

July 3.....Utica, N. Y., Hill Climb, Automobile Club of Utica.
July 3.....Sioux City, Ia., 300-Mile Race, Sioux City Speedway Assn.
July 3.....Westerville, O., Show.

Oct. 6-16 .....New York City, Ninth Electrical Exposition and Motor Show at Grand Central Palace.
Oct. 11-12.....Dayton, O., National Paving Brick Manufacturers' Assn., Annual Meeting.
Nov. 18..... Arizona 150-mile Grand Prix.
Dec. 31..... New York City, Show; Grand Central Palace.
Jan. 22, 1916....Chicago, Ill., Show; Coliseum.
March 4-11.....Boston, Mass., Truck Show, Mechanics Bldg.

The Week in the Industry

Miller Chalmers Assistant Sales Mgr.—H. W. Miller, formerly of Studebaker, has joined the Chalmers Motor Co., Detroit, Mich., in the capacity of assistant to the sales manager.

Suhr in Oregon—F. W. Suhr, special representative of the motor truck department of the Firestone Tire & Rubber Co., has been a visitor at the Portland (Ore.) branch for the past fortnight.

Wentworth Buys Out Portland Overland—Frank E. Wentworth, who is a partner of the Wentworth-Fosdick Co., Hupmobile distributors in Boston, and who has several other motor concerns in New England, has bought out the Overland branch in Portland, Ore., and in future it will be known as the F. E. Wentworth Corp. He has placed the agency in charge of E. A. Smith, who had charge of the Overland agency at Manchester, N. H., for some years. Salesrooms have been opened at the corner of Park and Congress Streets, and Mr. Wentworth had to give an order for 1000 Overlands to get the business.

—

Garage

N. Y. Co. Moves—The Bryant Motor Service Co. has moved into larger quarters at 1926 Broadway, New York City.

McNaull Tire Opens in Brooklyn—The McNaull Tire Co. has opened a branch in Brooklyn, N. Y., at 1246 Bedford Avenue, under the management of W. H. Byrnes.

Falls Tire in Seattle—H. H. Hazeltine and A. W. Hoppock are joint owners of the Seattle Tire & Rubber Co., 1624 Broadway, Seattle, Wash., representing the Falls tire.

Auto Utilities in N. Y.—The Auto Utilities Corp. has opened a salesroom at 1898 Broadway, New York City, for the sale of Disco electric lighting and engine starting equipment.

N. Y. Kissel Moves—Clodio & Engs, Metropolitan Kissel distributor, has moved into larger quarters in the new Circle Building, Central Park West and Sixty-first Street, New York City.

Toledo Garage Moves—The United Garage Co., Toledo, Ohio, will move Sept. 1 to larger quarters at Jefferson and Ontario Streets. M. R. Himes, manager of the concern, has taken a 20-year lease on the structure. The building is fireproof and will be equipped throughout with a sprinkler system.

Motor Men in New Roles

Halladay Resigns—C. L. Halladay has resigned as chief engineer and factory manager of the Lewis Spring & Axle Co., Jackson, Mich.

Emerson King Purchasing Agent—J. R. Emerson has been appointed purchasing agent for the King Motor Car Co., Detroit, Mich.

Chamberlain Garford Mgr.—R. E. Chamberlain is the manager of the Kansas City branch of the Garford Motor Truck Co., Lima, Ohio.

Bonniwell Assistant Advertising Mgr.—C. A. Bonniwell has been appointed assistant sales and advertising manager of the Auburn Automobile Co., Auburn, Ind.

Hobbs With Hoyt in Detroit—E. M. Hobbs has been appointed district sales manager of the Hoyt Electrical Instrument Works, Penacook, N. H., with headquarters at 967½ Woodward Avenue, Detroit.

Wayne's Temporary Officers—Temporary officers have been named by the Wayne Steering Wheel & Box Co. They are: J. C. Coleman, sales manager; Anthony Snyder, treasurer, and W. M. Wetherell, factory manager.

Tormey Frisco Tire Mgr.—James Tormey, formerly with the San Francisco branch of the Goodyear Tire & Rubber Co., is the new manager of the Service Tire and Oil Co., San Francisco, Cal., distributor for Nassau tires.

Hardin St. Louis Dealers' Secretary—W. O. Hardin has been made secretary of the St. Louis Automobile Manufacturers' and Dealers' Assn., succeeding P. J. Fisher, who has resigned. Hardin will assume his new duties July 1.

Dunham in Garfield Bldg.—G. W. Dunham, formerly vice-president and consulting engineer of the Chalmers Motor Co., who resigned to start into business for himself as a consulting engineer, has located his offices in the Garfield Bldg., Woodward Avenue, Detroit.

Jennings Dodge District Rep.—C. H. Jennings has been appointed district representative for Dodge Bros. in New York City. Mr. Jennings has been actively in charge since C. W. Matheson, formerly New York district man, became service director of Dodge Bros. several months ago.

See Winnipeg Mgr.—The Dominion Auto Supply Co. has been formed in Winnipeg under the management of G. W. See. This new concern has taken over the premises recently vacated by the Western Canada Motor Car Co., and will conduct a general garage and supply business.

Rengers Assistant to Pres.—F. H. Rengers in becoming the assistant to J. W. Moon takes charge of the correspondence department of the Moon Motor Car Co., and inside work and office work of an assistant nature to Mr. Moon. Mr. Rengers succeeds C. C. Culbertson to this position.

Colgrove Gets Hudson for Grand Rapids—L. E. Colgrove, who has been manager for the Mitchell Motor Sales Co., Grand Rapids, Mich., has become Hudson dealer in that city. He has secured quarters in the Burton A. Spring garage on Jefferson Avenue and will maintain salesrooms and a service station.

Jenkins Returns to Coast—W. M. Jenkins, who has been sales manager of the Master Carbureter Corp. since this concern was started in Detroit, Mich., last year, has returned to the Pacific Coast to take charge of the sales of the Master Carbureter Co., Ltd., Los Angeles, Cal. The business of the Detroit concern is now conducted from the new plant at 1523 Fort Street, West.

—

Dealer

N. Y. Remington Makes Lease—The Remington Motor Sales Corp. has leased offices in the United States Rubber Bldg., Broadway and Fifty-eighth Street, New York City.

Opens Seattle Repair Shop—H. V. Hoffman, formerly with the Buick in Seattle, Wash., has opened a repair shop and storage plant at 5322 Rainier Avenue, Seattle.

N. Y. Federal Truck Enlarges—The present quarters of the Federal Truck Co. in New York City have been found inadequate. Arrangements have been made to secure the whole second-floor space at 146 West Fifty-second Street, the company at present occupying the first floor. The first floor will be entirely devoted to service quarters, garage and repair shop, with an entrance directly off the street. The whole second floor is given over to showroom, general offices and sales department, together with a department for spare parts. The company has established a station in Newark, N. J., at 985-987 Broad Street.

VOL. XXXIII NEW YORK—THURSDAY, JULY 8, 1915—CHICAGO No. 2

The AUTOMOBILE

Belligerents Exhaust Swiss Output

Truck Factories Work All-Day Shifts—France Wants Gasoline Farm Tractors—New Magneto Industry Started in France

By W. F. Bradley

Staff Representative of the AUTOMOBILE *in Europe*

GENEVA, SWITZERLAND, June 17—Since the month of November Swiss automobile factories have been working at high pressure on orders for the German and Allied armies. A difficulty is experienced in getting raw material and in many cases trucks are delivered to foreign governments without magnetos.

The Saurer company, which occupies the leading position in the Swiss automobile industry, now employs 2000 men instead of 1500 before the war, and is operating a day-and-night shift. This firm has branch factories in both France and Germany and is supplying trucks to the German, French and English governments. It is estimated that the Swiss factory is producing eighty trucks per month. The output is limited to a certain extent by the lack of raw material. A few years ago the firm brought out a gun which gave good results, but at the present time it is not producing arms.

The Berna factory was stopped entirely during August and September. Since then it has been producing trucks at the rate of thirty per month, supplying them to France, England and Germany.

The Franz company is producing fifteen trucks a month, but as this concern is under German control the entire output is absorbed by Germany.

The Piccard-Pictet company is producing but a small quantity of complete automobiles, but has accepted contracts from the Swiss and foreign governments for car and artillery parts. There is a sufficiency of this class of work to allow the company to give it out in sub-contracts to other automobile and general engineering firms.

Martini is working with an increased staff of men producing touring cars for the Swiss and French governments. All private automobile trade has been stopped and it is impossible to export to England. With warring nations all around her, there is plenty of work for the Swiss factories on automobiles, or, if these cannot be produced, on gun parts.

PARIS, June 19—Orders have been issued by the French war department that the state arsenals and private factories producing guns and ammunition must be worked to their highest capacity. In order to make this possible all the necessary men have been released from service in the field to take up their former positions in the workshops.

The effect of this order will be to make the automobile factories busier than ever. It is doubtful if there is a machine shop in France which has not for months past been working for the army or navy. The military authorities, however, had the first call on the men, and recent investigations have shown that numbers of factories, although working 20 to 24 hours a day, were 10 to 30 per cent below their maximum production. Since the war broke out all shortage of machine tools has been met by supplies from America, and only men were needed to work these tools. Under the new regulations the increase in the output of munitions will be immediately apparent, for the entire organization existed and it is only a question of putting more men to work in the shops.

French Factory Activities

Automobile factories are particularly useful for the production of shells, machine gun tripods, aeroplane darts and bombs. All these can be produced economically with practically no change in the plant. The new orders will not make any change in the purely automobile work of the factories. By reason of her heavy purchases abroad France is well supplied with trucks, tractors and touring cars. There is a high demand for aeroplane motors, also for aeroplanes, but the factories specializing in this class of work are able to meet requirements.

Few Trucks Destroyed

During the present stage of the war the loss of automobiles is not excessive and is not likely to become so unless some dramatic military situation develops. So far as France is concerned, American manufacturers need not expect any important renewal of orders for trucks and cars. The army is well supplied and big reserves of automobiles are held. A serious reverse or an important success could so change the

Aultman and Taylor gas tractor from Ohio hauling a plow in France

conditions of operating that losses of trucks would be increased and more orders would have to be placed, but until that occurs France need not be expected to come into the market for a further big quantity of automobiles.

American Tractor Trade

Recently the Knox company's four-wheel-drive tractor has successfully passed army tests and an order has been placed for early delivery. The three-wheel type of tractor did not meet the approval of the French army authorities.

The four-wheel-drive tractor, which is a special proposition and very highly thought of by French military authorities, can only be produced in France in limited quantities and is not made at all in other European countries. Hence there is always an opportunity for America to supply more of this type of vehicle.

Light-Truck Orders

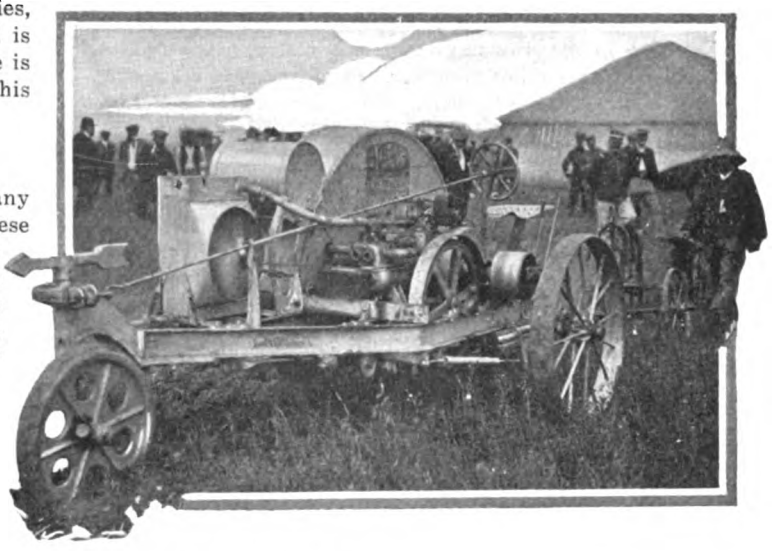
Orders have also been placed with the Jeffery company for light trucks running on pneumatic tires. Many of these have already been delivered. The French factories have supplied thousands of this type of automobile, for it is nothing more than a stout touring car chassis, and is made use of for light haulage and ambulance work. They might have been produced by the home factories, but the view of the authorities evidently was that it was cheaper to buy abroad than interrupt the shell making of the automobile factories. It can be taken as absolutely certain that when more automobiles are needed in the French army they will be secured from America, for it is better policy the keep the factories running uninterruptedly on shells than to switch them backward and forward from ammunition to cars. This, however, does not prevent the car departments of certain factories working at constant pressure for the army. The point is that when bigger numbers of automobiles are required an attempt is not made to get them out of the home factories, but recourse is had to America.

France Buys Direct

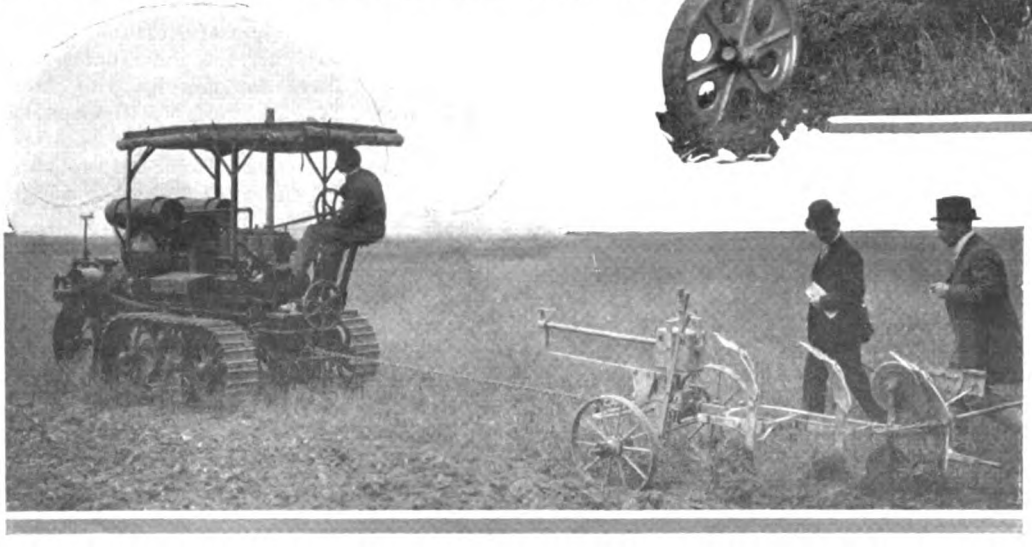
It is interesting to note that so far as France is concerned a comparatively small number of American firms have been able to get orders. The complete list of these firms is doubtless as follows: White, Pierce-Arrow, Packard, Kelly-Springfield, Jeffery quad and truck, Knox quad, Sternberg, and one make of American caterpillar tractor. There are scores of other American firms which have automobiles in army service in France, but they have never secured direct army contracts. Ford, for instance, has some hundreds of model T chassis in ambulance work, but it does not appear that the French army has ever bought one of these automobiles.

The English and the Canadians have bought and brought over all kinds of American trucks and automobiles, for much of their business is done through intermediaries. From the beginning the French war department has sought to keep the purchase of automobiles entirely in its own hands and has so well succeeded that it is hard to find an intermediary who has gained admission to the offices in the Boulevard St. Germain. A lot of enterprising salesman have come to Paris with catalogs and samples, but have sooner or later come to the conclusion that London and Petrograd are better places of business.

One field open right now to the American manufacturer is



Light Bull tractor which met with the approval of the French agriculturists



Bullock gasoline tractor being demonstrated to a French farmer

French officers on one of the Jeffery Quad trucks

Sending finished shells away on an American truck

the supply of agricultural gas tractors. There is and will be for a long time a dearth of agricultural labor and this shortage can only be met by the use of motor tractors. The French farmer is ready to adopt such machines. For 6 years he has been carefully educated to the value of gasoline on the land, this work having been undertaken by both automobile and farmers' associations, and if the average farmer has not broken away with tradition he has at any rate been convinced in his own mind that at some date he would have to make use of motor traction in his fields. The war has determined that that date shall be the year 1915.

Farm-Tractor Demonstration

As an indication of the seriousness with which this problem is being studied, a practical demonstraton of gas tractors in use on the land was made a few days ago in an important agricultural district 40 miles to the southwest of Paris. It is a mighty difficult matter at the present time to get up any demonstration in France which does not have the prosecution of the war as its direct object. Thus it is most significant that this event should have been attended by an official delegate from the Ministry of Agriculture, by French staff officers, by officers attached to the corps charged with the work of relieving civilian distress, and by the leading farmers of the surrounding country. The demonstration had been organized by the enterprising French agent of an American machinery company and comprised five makes of machines, four of which were entirely suitable for French conditions. Immediate business will be done here, and furthermore it will be of a permanent character.

French Farmer Slow

It must not be supposed that because the French farmer is now buying or intends to buy gas tractors that he is in the market for touring cars. It is a difficult matter to hurry the French agriculturalist into luxuries, and while a farmer is ready to believe that a tractor is a good business proposition, it will take a lot of argument to convert him to the use of a car for ordinary traveling.

Immediately after the war there will be an opportunity for the American automobile manufacturer to secure some business in France, but that business will not be done among the purely agricultural classes. Particularly, if the war ends abruptly, French, and indeed all European factories, will be unable to meet the demand for touring cars. This gives the American an opportunity to step right in, but advance arrangements will have to be made in order to do so.

There is also the fact that Germany will no longer be able, in view of public opinion, to market her wares in France. Her hold on the French automobile business was not great, but it is nevertheless worth considering. More important is the accessory business, of which Germany held a big share. This market is entirely open to America. The French do not excel in tools and accessories, Germany who held much of the business, will be wiped out, England will be too busy in other directions, and there is moreover, a very favorable impression toward this line of American products.

The prospect of after-the-war supply of American trucks to France is not brilliant. Whatever the conditions of peace, there will be more gasoline haulage after the war than ever occurred before. But the fact has to be faced that some thousands of trucks of both French and foreign construction will be released from military service in fairly satisfactory condition. These will be sufficient to meet civilian requirements for a year, perhaps more, and certainly until a return to normal working conditions.

As a result of the war the French army authorities will extend the truck subsidy scheme, thus making it impossible for foreign manufacturers to compete with home firms. One of the leading American firms doing touring car business in France and selling war trucks in various parts of Europe is so sure that development will be on these lines that no attempt is being made to cater for the ordinary French trade.

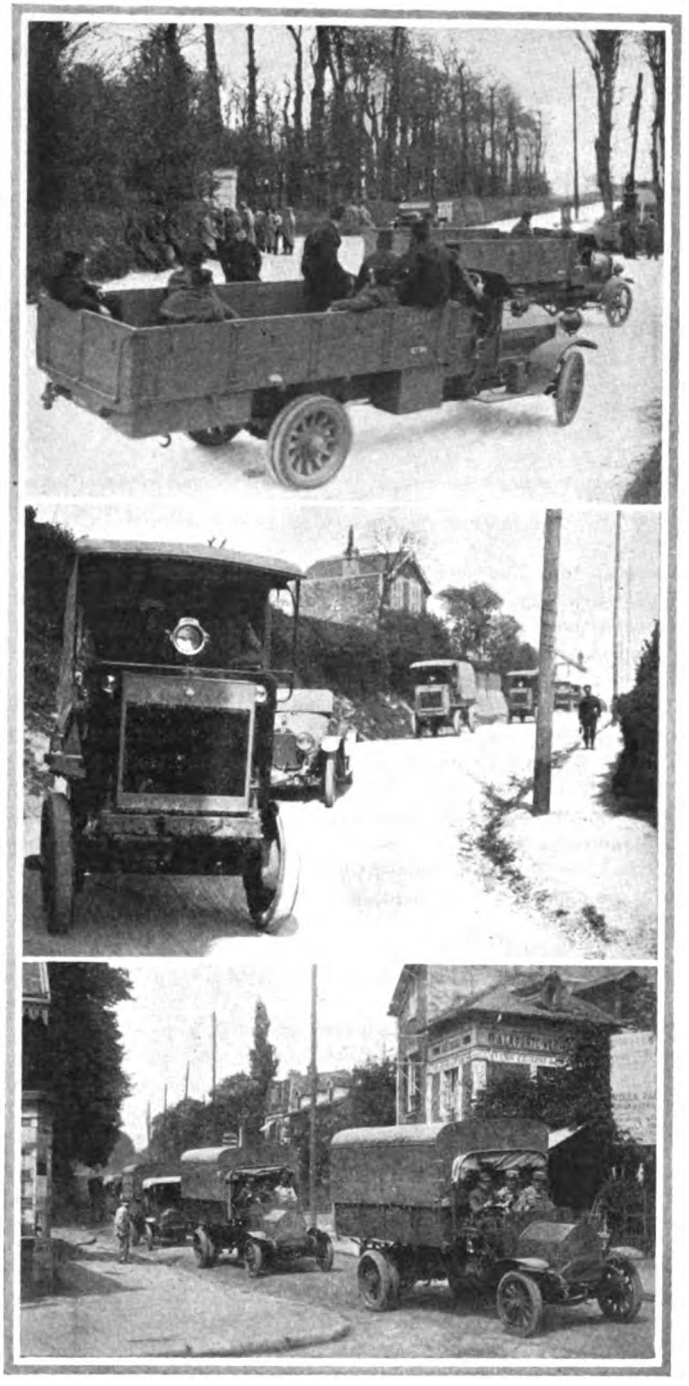
—

Founding Magneto Industry in France

PARIS, June 15—France is through with German magnetos. How near she was to the disaster of a magneto famine and how cleverly she made herself independent of products from across the Rhine is one of the best stories related in connection with the industrial organization of the war.

Last November the shortage of magnetos had become so serious that the Minister of War called in Louis Renault, the leading automobile manufacturer of France to ask him to suggest a solution. At that time the factories were working at full pressure, 22 to 24 hours a day, and seven days a week. Gnome and Renault were each producing nearly 100 aeroplane motors per week; Clerget, Salmson, Anzani, Le Rhone were building smaller quantities. These special aeroplane motors could not be bought in America, or indeed from any other European country. Every factory in France capable of making heavy or light trucks was employed to the utmost of its capacity. The touring car factories were producing such cars as were required and at the same time specializing on shells. Neutral Switzerland was filling truck orders for France, but only accepted the orders on condition that delivery should be made minus magneto. Italy, until the moment she declared war, was in the same position.

Louis Renault's reply to the Minister of War was that he could not personally undertake the construction of magnetos,



Top—English truck employed for work in the French army
Center—Jeffery Quads going through Northern France into Belgium
Bottom—Convoy of requisitioned Saurer trucks on the road in France

but he suggested a means whereby an immediate and permanent remedy could be secured. Within an hour of that interview an order was signed calling out of the firing line Soldier Dutreux, who from the first day of August to the beginning of November had been shouldering a rifle. Under the blue-gray uniform of Soldier Dutreux was a former manager of the Dunlop Tire Co., a director of the S. E. V. electric lighting company, a successful business manager of the Panhard-Levassor Co., in a word, one of the best organizers and business managers of automobile France.

When the war broke out the French government had sequestered, in common with all other German property, the factory and offices of the Bosch Magneto Co. in Paris. A complete inventory of the stock was taken by a public receiver, the Bosch sign was removed, and the French manager of the factory continued to build magnetos on a small scale for the French army authorities. So far as the public was concerned, the firm was in exactly the same position as a bankrupt company in the hands of an official receiver.

Foreman from the Front

Soldier-manager Dutreux received army orders to lay down his rifle, take charge of the Bosch factory and produce the greatest number of magnetos in the shortest possible time. Probably the efforts of such a capable manager would not have been productive of great results but for the forethought of the French war department. For the last eight or nine years the French army has held an annual truck competition, the successful vehicles in which were eligible for State subsidies. So successful has been this scheme that every truck maker in France takes part in it, and the last competition brought to a close by the declaration of war, had united 150 vehicles. One of the stringently observed clauses of this competition was that the whole of the truck must be produced in France, of French material, by a firm under French management. As an example, the Goodrich Tire Co., which supplied some of the rubber tires for these trucks was only eligible for this work by reason of having a French factory, obtaining its supplies from French sources, and working under the control of a technical director amenable to French military laws.

The Bosch company supplied a large proportion of these truck firms with magnetos, but those magnetos were constructed entirely in the Paris factory, and the whole of the material used in their construction was produced in France. Further, although the company was under German control, the technical head of the Paris factory was a Frenchman eligible for military service in the French army. The severity of the competition guaranteed the French-made magnetos being equal in every respect to those built in Germany; failure from any cause entailing disqualification, the individual manufacturers would have refused to fit a magneto which did not possess every guarantee of excellence.

Made Complete Magnetos

By this arrangement Manager Dutreux was in charge not merely of an assembly plant, but of a small, efficient factory producing complete magnetos. Starting in on the first day of November, Manager Dutreux had so organized his forces that on the first day of January the output of the factory was three times greater than it had been at any previous period of its history. The supply was sufficient to meet all the demands for aviation motors delivered to the French and several of the allied armies, France is supplying Belgium, Russia, Italy, and England to a small extent, and left a margin for trucks and touring cars.

The seriously threatened magneto famine had been averted. When the men were wanted for this work, an order signed by the war department brought them out of the trenches; if supply houses were hanging back in the matter of deliveries, the war department supplied the men from out of the ranks and requisitioned the material if it could not be obtained otherwise. Every man in the magneto factory, from the managing director to the caretaker, was under military orders. They had cast off their uniforms, but they had not been freed from military obligations. Instead of the cent a day they were entitled to draw in the firing line, they were paid the same wages as before the war.

While this work was in progress, plans were being laid which would make the French automobile and allied industries independent for all time of German magneto supplies. Two years ago Louis Renault founded the S. E. V. company for the production of electric lighting and starting outfits for automobiles. Eight other French car manufacturers were associated with Renault in this work. It was this company

(*Continued on page* 59)

Maxwell—Mercer—Duesenberg July 4 Winners

Sioux City

Rickenbacher in Maxwell first, averaging 74.7 m.p.h.

O'Donnell, Alley and Chandler, all in Duesenbergs, made 74, 71.25, and 65.85 m.p.h., respectively.

Orr's Maxwell was fifth at 64.40 m.p.h.

Shrunk's White averaged 61.20 for the race.

Tacoma

Ruckstell in the Mercer won the 250-mile Montamarathon at 84.5 m.p.h.

Pullen sent his Mercer over the finish line in the 200-mile race for the Golden Potlatch Trophy a winner at 85.2 m.p.h.

Parsons duplicated his feat of last year in winning the 100-mile Intercity.

Omaha

Making the highest average of any of the July 3, 4 and 5 races, Rickenbacher sent his Maxwell over the route to victory at 91.74 m.p.h.

O'Donnell made a good record with his Duesenberg—86.16 m.p.h. after a speed duel with the winner.

Orr's Maxwell took third place handily with an average speed of 82.3.

MAXWELL, Duesenberg and Mercer racing cars shared the leading honors of the speedway events held on July 4 and 5 at Omaha, Tacoma and Sioux City. Maxwell's were first at Omaha and Sioux City and Mercers won two of the three races at Tacoma. Duesenbergs took second prize at Omaha and second, third and fourth at Sioux City. A Maxwell was third at Omaha and fifth at Sioux City.

Highest Speed at Omaha

From the point of view of speed the record made on the little 1.25-mile board track at Omaha was far above those made at either Tacoma or Sioux City, although below the 91.58 m.p.h. recorded at Chicago, June 26, being 91.74 for Rickenbacher's Maxwell. Second and third drivers were well up, O'Donnell's Duesenberg averaging 86.16 and Orr's Maxwell 82.3. One reason for the speeds being lower than those at Chicago was that the drivers were afraid to open up too much on the small track for fear of losing control.

The results of the various races bring out strongly the value of the plank surface as a promoter of high speeds, the Omaha averages as well as those at the newly boarded Tacoma track being well above those made on the dirt track at Sioux City. It is evident that the board surface offers much better and more uniform traction with less tendency to skidding than the dirt track. It also gives the drivers greater confidence and enables them to get higher efficiency from their cars.

At Tacoma the speeds were 85.2 m.p.h. for Pullen's Mercer, winner of the 200-mile Potlatch race with 85 m.p.h. for Cooper's Stutz which was second, 79 for Ruckstell's Mercer in third position and 78.8 for Oldfield's Peugeot. In the Montmarathon over a 250-mile course Ruckstell's Mercer averaged 84.5 m.p.h. with Cooper's Stutz a close second at 84.22 and Pullen's Mercer third at 84.20. Burman and Oldfield in Peugeot's made 79.5 and 75.8 m.p.h., respectively. In the Intercity 100-mile event Parsons averaged 79.5 in his Parsons special, while Elliott in the Gordon was second at 74.7, the other averaging under 65 m.p.h.

At Sioux City Rickenbacher averaged 74.7 m.p.h., and O'Donnell's and Alley's Duesenbergs were close behind with 74 and 71.25 m.p.h., respectively. Chandler's Duesenberg made 65.85; Orr's Maxwell, 64.40, and Shrunk's White, 61.20.

Three Fatal Accidents

Three deaths marred the July 3, 4 and 5 racing this year, Billy Carlson and his mechanician Franzen being killed at Tacoma when a tire blew out on a turn and threw their car over a 30-ft. embakment. Franzen was killed instantly and Carlson, though rushed to a hospital, died without regaining consciousness. The third death was that of C. C. Cox, who drove the Ogren at Sioux City. Cox swung out to permit Rickenbacher to pass at the same time that another car was coming up behind which forced Cox to swing back again, and in so doing he struck wheels with Rickenbacher which threw the Ogren through the outside fence where it turned over. Cox was injured on Saturday and died on Sunday. His mechanician, McGraw, was also injured.

Maxwell Leads at Sioux City

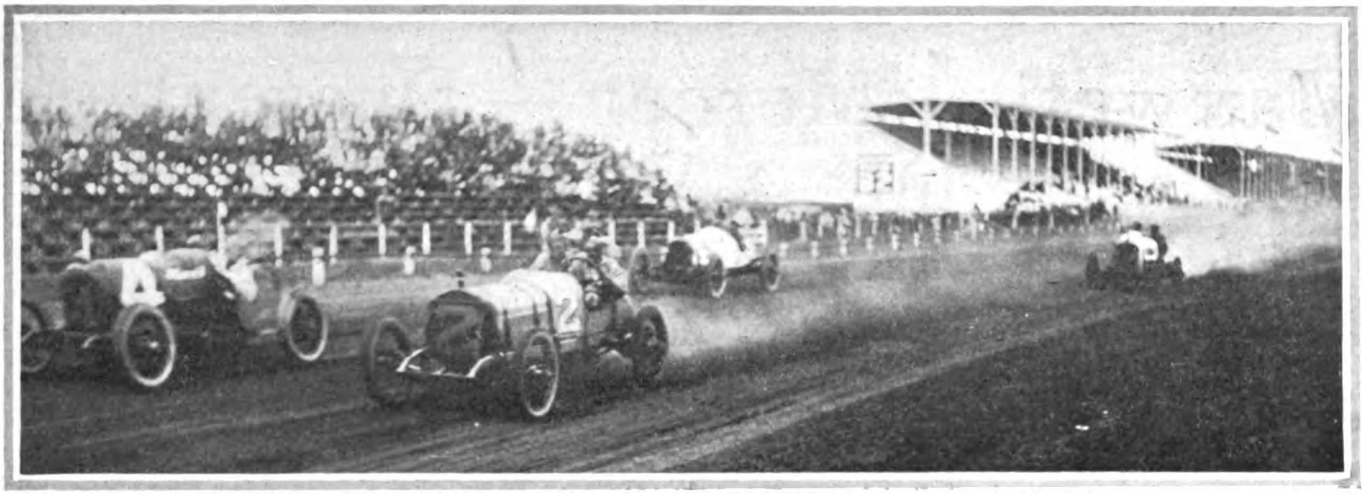
SIOUX CITY, IOWA, July 3—Rickenbacher, driving a Maxwell, won the 300-mile race here to-day on the 2-mile dirt speedway at an average of 74.7 m.p.h., a speed relatively slow in comparison with Indianapolis and Chicago speedways and also slow as compared with a speed of 78.8 m.p.h., made a year ago on this same dirt speedway here by the same Rickenbacher when he won on a Duesenberg. To-day the track was slow, due to incessant rains and scarcely more than 25 miles of the 300 were covered when the home stretch and one of the turns began breaking up and from that time to the finish the race was a severe test of the skill of the drivers and the stamina of the cars. The test to which the cars were put by this unusual track condition is best explained by the fact that of the fifteen starters which were sent away at 12.30 sharp, only six were able to finish the 300 miles by 5.30 p. m., the time set for the completing of the three centuries. The track was in good shape at the start but the 75 m.p.h. pace soon proved too much for it.

Finishers at Sioux City Race

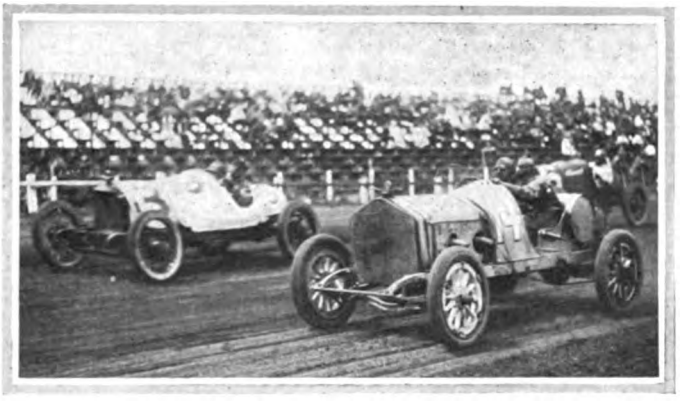
CAR	DRIVER	TIME	M.P.H.
Maxwell	Rickenbacher	4:00:56	74.7
Duesenberg	O'Donnell	4:03:21	74.0
Duesenberg	Alley	4:12:31	71.25
Duesenberg	Chandler	4:33:21	65.85
Maxwell	Orr	4:39:40	64.40
White	Shrunk	4:54:08	61.20

A Neck-and-Neck Race

To-day's race is the first important victory for Rickenbacher since he won on this speedway a year ago. He did



Rickenbacher in the Maxwell leading Shrunk in the White on the Sioux City dirt speedway



A lively brush between Alley's Duesenberg and the National in the Sioux City 300-mile race

not have matters at all his own way to-day. In fact it was a neck-and-neck race from start to finish with a Duesenberg entry, driven by O'Donnell. During the 300 miles the Duesenberg was never a lap behind the one leader and for 10 miles O'Donnell led Rickenbacher's Maxwell. At the finish O'Donnell was less than 2¼ min. behind the Maxwell. The fight between these two leaders might have been much closer had it not been that the Duesenberg was handicapped by a broken water pump which made it necessary to run the last 4 miles of the race without water. Rickenbacher's time for the 300 miles was 4:00.56, and O'Donnell's time was 3 min. and 21 sec. slower, his average being exactly 74 m.p.h.

Duel Between Rickenbacher and O'Donnell

These two contestants, Rickenbacher and O'Donnell, made the race from start to finish, and there were no other serious contenders for first or second place at any time.

Third honors went to Alley, driving another Duesenberg, who averaged 71.25 m.p.h., and was over 12 min. behind Rickenbacher. Alley ran consistently 6 miles or three laps behind the leaders, and nearly 20 min. ahead of the remainder of the field.

Chandler, in a third Duesenberg was fourth, at an average of 68.85 m.p.h.; a Maxwell driven by Orr was fifth at 64.40 m.p.h., and a local White, driven by Shrunk was sixth, averaging 61.20 m.p.h. These six were all the cars that finished. The performance of the Duesenbergs finishing second, third, and fourth was the feature of the race, after the duel between Rickenbacher and O'Donnell.

Donaldson in the Emden and Cooper in the Sebring were flagged while they still had several miles to go; and the remaining seven of the fifteen starters dropped out, five of them being eliminated before the 70-mile mark was passed.

Of those eliminated Resta in his new Peugeot, winner of the recent Chicago race, winner of second place at Indianapolis, and winner of the Grand Prize and Vanderbilt Cups at San Francisco, was looked upon as the greatest disappointment, as this entry played a major part in attracting many of the 20,000 spectators. Resta was never a factor, in fact, he never seemed interested in the race. He considered the course dangerous, and was out at the end of 12 miles with a broken oil lead and a broken bolt in a crankshaft bearing. While running he did not at any time appear to challenge Rickenbacher and O'Donnell, who led from the start.

One Fatal Accident

Only one accident marred the race. C. C. Cox, driving the Ogren, was injured and his mechanic, McGraw, also injured when Cox swung out to permit Rickenbacher to pass. At this moment Cox saw another car coming up behind and swung back again, but in doing so struck wheels with Rickenbacher, which threw Cox to the side, the car going through the outside fence and turning over. The wheel on Rickenbacher's Maxwell was slightly damaged, the most serious aspect of it, however, being the delay to change. Rickenbacher almost had to go through the fence to avoid crashing into the wreck. He was able to keep his car from upsetting and continue the race without losing the lead. Cox had his right leg broken, together with some ribs fractured, and the mechanic sustained fractured ribs and dislocated shoulder. Cox died of his injuries on Sunday. His mechanician is expected to recover.

Rickenbacher Takes the Lead

In the duel between Rickenbacher and O'Donnell, Rickenbacher took the lead at the end of the first lap and was at once pursued by O'Donnell's Duesenberg, together with Alley in the other Duesenberg. Resta's Peugeot was back in the field. At the end of the second lap the three leaders were making a runaway from the rest of the field and had lapped some of the other entries. Resta was running in seventh place. At this early point in the race the Sebring stopped at the pits as did the National entry.

Alley a Close Third

At the end of 20 miles Rickenbacher was leading O'Donnell's Duesenberg by fewer than 10 seconds, the Maxwell having averaged 75.5 m.p.h., or covering the 20 miles in 15.42. Alley, in the second Duesenberg, was less than 1 minute behind the leader. Resta's elimination at the twelfth mile was due to two causes, first a broken oil lead, and second a broken center bearing bolt which holds the outer ball race for the ball bearings carrying the crankshaft into position. The main oil lead had a rubber connection at its lower end and it

was this connection which punctured, allowing all of the oil flowing through it to drop outside of the motor.

O'Donnell 10 Sec. Behind

At the end of 40 miles Rickenbacher had his Maxwell still in the lead having averaged 78.9 m.p.h. O'Donnell had his Duesenberg but 10 sec. back of him and the second Duesenberg was trailing less than a minute back of the Maxwell. Soon Alley had to stop at the pits for some motor adjustment which placed him three laps behind, which did not endanger his third position as he was running more than 6 miles ahead of the rest of the field.

Sixty miles saw Rickenbacher, O'Donnell and Alley, running one, two, three, and miles ahead of the others. At this point the Maxwell averaged 76.6 m.p.h., O'Donnell was now 20 seconds back and Alley 6 miles back. O'Donnell all the time was making a persistent fight to overtake the speedy Maxwell but the dirt turns were getting so badly cut up and the home stretch was so rough that it was dangerous to attempt passing at this speed.

At 80 miles the positions remained unchanged, Rickenbacher averaging 76.6 m.p.h., O'Donnell was holding his position, Alley was 5 miles back, and 8 miles to the rear came the next group of drivers led by Orr in the Maxwell with Chandler in the third Duesenberg pursuing him. The White, Emden, Sebring, and Mulford were trailing.

By leading at 100 miles Rickenbacher won the $500 prize for premier position at this point, his average being 77.55 m.p.h., and his time for the distance, 1:18:24.30. O'Donnell was 1 min. and 16 sec. behind him.

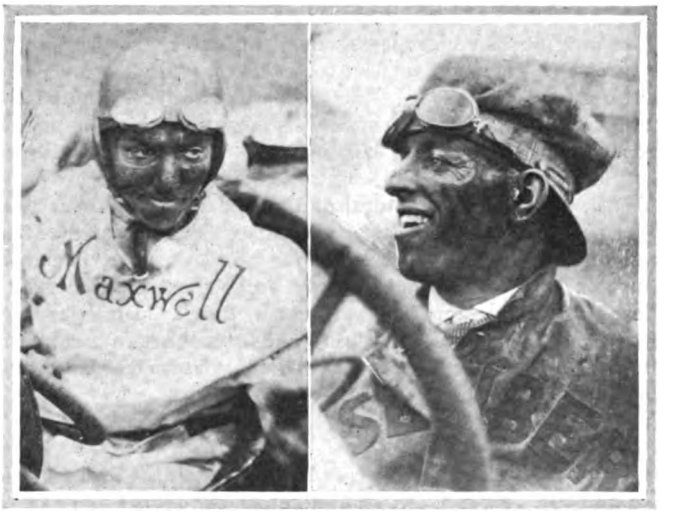
It was soon after this that Rickenbacher's collision with Cox nearly cost him the race and when he was signalled to stop at the pits and change the damaged wheel, many of the spokes of which were loose, O'Donnell took the lead, passing the pits just as the Maxwell was getting out after changing the wheel. The Duesenberg lead was short lived as Rickenbacher had his Maxwell in the lead in less than 2 miles, due to O'Donnell having to stop at 116 miles, to replace a punctured tire.

O'Donnell Struggles to Keep Lead

From 116 to 126 miles there was a neck-and-neck struggle between Rickenbacher and O'Donnell, with O'Donnell leading at 120 miles with a margin of less than 2 sec. and maintaining an average of 78.5 m.p.h. Rickenbacher was able to take the lead at 126 miles and was never headed from that point. At 130 miles he had increased his lead to 16 sec.; at 140 miles it was 26 sec., the average maintained being 75.3 m.p.h. At this time the course was getting rough with dust rising in clouds on the turns. On the home stretch the best part of the track for the cars, was a narrow one, well toward the outside fence. Some of the slower cars started driving on this track and several of them had to be signalled in by the officials because that was the part of the track on which the higher speed cars should travel. Because of this trouble some of the faster cars had to pass on the wrong side, namely next to the pole. At 148 miles Rickenbacher was signalled to stop and cautioned against passing on the wrong side, and it was while he was being warned that O'Donnell came down the stretch and it looked as if he would take the lead from the Maxwell, but instead he pulled into the pits for his first stop and the Maxwell was able to maintain its lead. O'Donnell replenished with gasoline, oil and water in 10 sec.

Rickenbacher Still in Front

At 160 miles Rickenbacher was averaging 74.3 m.p.h., with his Maxwell. O'Donnell was 1 min. and 20 sec. behind him, and Alley was holding the other Duesenberg in third place 6 miles to the rear. The other positions were Orr's Maxwell, Chandler's Duesenberg, and White, Emden, Sebring, and Mulford bringing up the rear at a pace of 40 m.p.h. None of the trailers had stopped at the pits up to this time, and as there was the silver trophy for the car running the greatest distance without a stop the rivalry among these trailers was interesting. Orr surrendered his chances by stopping at 172 miles, White stopped at 192, thus letting Chandler win with his Duesenberg by making 224 miles at which time he made



Left—Rickenbacher at the wheel of his winning Maxwell after the Sioux City race

6	Maxwell (Six)	Orr	3.75	6.75	292.2	Master	Bosch	Nassau	Oilzum	Houk
2	White	Shrunk	4.6	5.75	447.0	White	Bosch	Silvertown	Monogram	R-W

NOTE—All cars were equipped with Bosch magnetos and carried Hartford shock absorbers and motometers.

his first stop, taking on fuel. Up to this time the Duesenberg and White had been running in the same lap the entire distance.

From this point, 160 miles, the position of the leaders remained unchanged until the end of the 300 miles. Rickenbacher led at the end of 200 miles, taking the $500 money for leadership at this point. His average was 74.5. O'Donnell's Duesenberg was 1.5 min. back.

When the finish of the 300 miles came, Rickenbacher's lead was just 2 min. and 14 sec. on the Duesenberg. The Maxwell's average was 4.1 m.p.h. slower than the time made by Rickenbacher a year ago when he won with a Duesenberg.

Mulford's Car on Fire

Ralph Mulford in his Mulford special, who had reduced his speed to about 35 m.p.h., caught fire 98 miles from the finish, the Emden and Sebring being the only other cars running at the finish.

Sioux City Track Hard on Cars

SIOUX CITY, IOWA, July 3—That a dirt speedway deals death to motor car mechanisms and that only cars of quality and stamina can withstand the terrible grind, especially if the track is not in good condition, was proved conclusively at the second annual 300-mile race at Sioux City, July 3.

Running at 75 m.p.h., it required well-made cars and good drivers to finish in the money, for every part of the machines had to come into service. Vibration was carried to the maximum, side strains on the turns were heavy, taxing the steering mechanism and the wheels greatly. It was a surprise to many of the officials and spectators that as many as six cars finished, these making a total of thirteen stops or about two stops per car for 300 miles. The entire fifteen cars made a total of sixty stops or exactly four stops per car, but this figure is brought so high mainly because of two local entries, a National and a redesigned Buick. Disregarding these two cars, which really were not fit to start in a contest, there were thirty-one stops debited to thirteen cars, an average of three stops per car.

Track in Poor Condition

In the board and brick speedway races, at Chicago and Indianapolis respectively, the high speed of the cars was mostly responsible for the pit stops, but at Sioux City, where the average speed was much lower, it was the poor condition of the track which made riding difficult, though on the whole the cars which finished in the money made a remarkable showing. The motors were taxed excessively because most of the drivers used a rear axle reduction not fit for the track. There was only one car with a 3 to 1 axle, the remainder having 2.75 and under.

The track was badly rutted and made pulling at any reasonable speed a difficult matter and in not a few cases did drivers have to shift to an intermediate speed to pull out of the bad spots. This gives one an idea of the roughness of the course and the really good performance of those cars and drivers which won prizes.

Why the Cars Went Out

The first car to abandon the race was Resta's Peugeot, which was disabled on the back stretch because of two things. The center bearing, which is of the ball type, had its outer race held in position by four bolts. One of these was broken before the car started and the remaining three were sheared allowing the bearing to turn upon its support in the crankcase. Aside from this the main oil lead became punctured allowing the lubricant to flow into the mud pan and thus become wasted. Resta went out before finishing 14 miles and it was thought by many that the driver abandoned the race because he feared the track was not safe.

The next car to leave the course was the O. C. special, driven by Shea, a local driver. He retired in his twenty-sixth mile with a complication of troubles. He had separate exhaust pipes and lost one of them, also his valves were giving trouble and the motor was firing on two cylinders only.

A National entry driven by a local man went out in its sixtieth mile with a loose connecting rod, an overheated motor, and carbureter trouble.

Rickenbacher Made Three Stops

Rickenbacher, who carries away $7,000 in prize money, which includes first and $500 each for leading at 100 and 200 miles, made three stops in all, losing a total of 2 min. and 25 sec. His first stop was made in his 66th mile when he came in with a flat right rear tire. The next stop was made in the 104th mile when he came in to change a left rear wheel which became badly damaged when it was previously struck by the Ogren's right front wheel. Advantage was taken of the stop and all tanks were filled. The tire was not blown but became defaulted because of a slow leak or puncture. Oil was also taken on. Rickenbacher's last stop was made in his 148th mile when Starter Wagner called him in for advice. Rickenbacher was passing cars on the left side instead of the right, but this was necessary apparently, because many of the slower cars in the race were piloted by men who did not know the rules. These drivers kept to the outer rail instead of the inner causing the fast cars to pass on the left side, or slow down to 50 m.p.h., with possibly dangerous complications.

O'Donnell Lost Only 1 Min. 60 Sec.

O'Donnell in a Duesenberg, who finished second, lost only 1 min. and 60 sec. during the entire race. His first stop was made in his 150th mile to fill all tanks and his second in his 218th mile for water. O'Donnell never changed a tire. His second stop would not have been necessary had not the water pump sprung a leak. It appears that a small hole became enlarged because of the excessive pressure, and water was being lost at a great rate.

Alley Made Three Stops

The Duesenberg which finished third, driven by Tom Alley, made three stops, losing a total of 4 min. 6 sec. The first of these was in the 198th mile for water and oil, the second in the 222d mile for clutch trouble. The clutch was slipping badly and after treatment with rosin it held without trouble. The third was made in his 278th mile for a right rear tire which had blown and also water and oil.

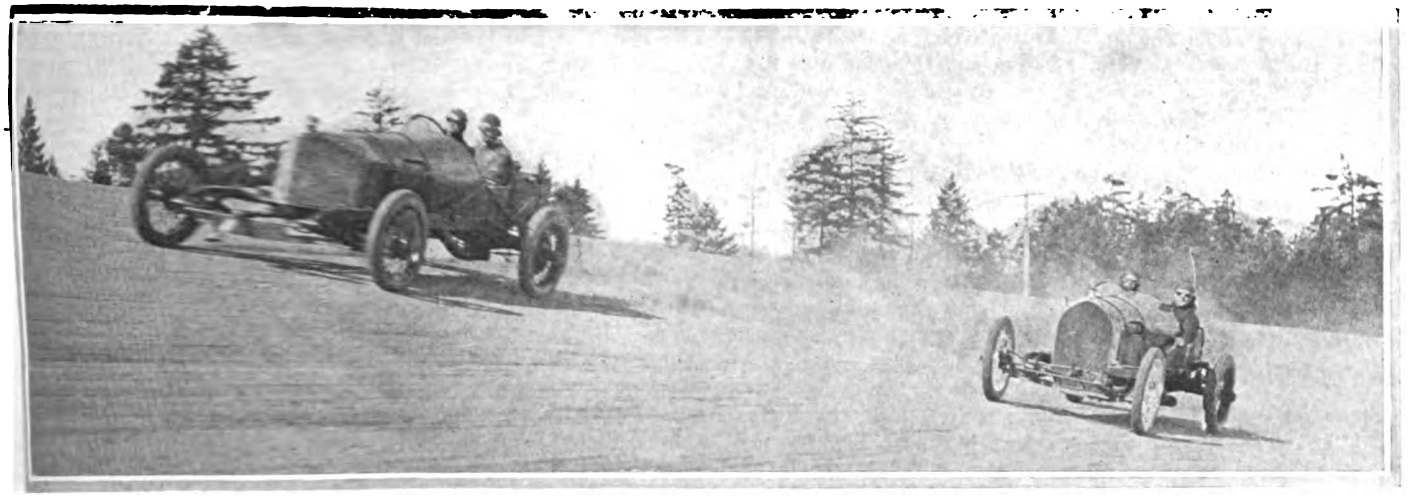
Tom Orr in a Maxwell drove a consistent race, stopping but twice, once in his 168th mile for supplies and again in his 226th mile for two new spark plugs and water and oil. In all he lost about 7½ min. at the pits.

The only local entry to finish in the money was the White six driven by Shrunk and he made two stops, the first at 180 miles for supplies and the second at 276 for water and oil and universal trouble. Shrunk was at the pits a total of 9 min. 5 sec.

Emden, Sebring and Mulford Still Running

The Emden, the Sebring and the Mulford were running when the race was called at 5.30 p. m. The first-named finished 290 miles and stopped three times, the first at 120 miles for lubricating trouble, the second at 168 miles for

Mercer Dual Winner at Tacoma



Pullen and Ruckstell, the Mercer drivers who won the Montamarathon and Potlatch races at Tacoma, making 98 m.p.h. on the newly planked speedway

supplies, and the third at 182 miles for new spark plugs. A total of 5 min. 52 sec. was lost.

The Sebring lost about 13 minutes and made seven stops at the pits, the first at 22 miles for water, the second at 56 miles to repair an oil leak, the third at 68 miles with a slipping clutch, the fourth at 80 miles with an oil pump leak, the fifth at 100 miles with clutch trouble, the sixth at 134 miles with the same trouble, and the last at 196 miles for water and oil.

Mulford, driving the same car he piloted at Chicago on June 26, made a total of eight stops, losing in all 23½ min. The first stop was at 36 miles to change all four tires from Silvertown cord to Nassau. His second stop in his 44th mile was caused by a broken radiator which caused overheating troubles until the time the race was called. Carbureter trouble also developed and because of the overheating the plugs had to be changed in the 88th mile.

In the Way of Equipment

Every car which finished in the money used a Bosch magneto and Bosch spark plugs with the exception of Tom Alley and Chandler who used a Bosch magneto and Rajah plugs. The race was won with a Zenith carbureter. Nassau tires were used by Rickenbacher, by Chandler who finished fourth, and Orr in fifth position. All cars starting used Hartford shock absorbers and Boyce motometers.

William Carlson, Maxwell driver, who was killed in the races on the Tacoma 2-mile board speedway. He was born and reared in the vicinity of Los Angeles and belonged to the later-day generation of coast drivers. He finished in ninth place in the recent Indianapolis race

Ruckstell and Pullen Win Two Leading Events—Parsons Wins Intercity for Second Time—Board Speedway Fast

Three-Race Program

TACOMA, WASH., July 5—The 2-day racing on the newly planked 2-mile speedway evolved three popular winners in the three races held in conjunction with the Montamara festival, Ruckstell, in a Mercer, winning the 250-mile event, at 84.5 m.p.h. or 11.1 m.p.h. faster than the time made by Cooper in the Stutz last year; Pullen, also in a Mercer, capturing the 200-mile race at 85.2 m.p.h., or 11 m.p.h. faster than the time made by Hughes' Maxwell in 1914; and Parsons, in the Parsons special, duplicating his feat of last year, in winning the 100-mile Intercity grind at 79.5 m.p.h., or 5.9 m.p.h. faster than the time he made last year in the Frantz. The main factor in the great increase of average speed was the plank surface of the 2-mile track

which was much more adapted to high speed and less conducive to skidding than the dirt surface over which the races were run last year.

Earl Cooper Second

Second to Ruckstell in the 250-mile Montamarathon Trophy Race, was Earl Cooper, in his Stutz, who finished at an average speed of 84.22 m.p.h. Pullen's Mercer was third at 84.20. Burman was fourth, sending his Peugeot over the course at 79.5 m.p.h., and Oldfield, also in a Peugeot, was fifth at 75.8. Cooper made the fastest of the 129 laps of the race, covering the course at an average speed of 89 m.p.h.

Thirteen cars started in the race, the five mentioned being the only ones to finish. Ruckstell led most of the way by one or two laps and from the 105th circuit was never headed, although the winners were but a few yards apart at the finish. Cooper drove a beautiful race, going to the pits once in the 103d lap and at the finish was driving carefully on worn tires rather than risk a delay at the pits in making a change.

Some Clever Driving

The eight-cylinder Romano ran steadily until the forty-third lap when it took fire and was burned. The Gordon special skidded dangerously three times in the 114th lap on a curve ahead of Cooper, but by wonderful control Elliott managed to slide clear amid the cheers of the 30,000 spectators who braved the heat to watch the speed carnival.

Carlson and Mechanic Killed

Driving on the back stretch on the sixtieth lap Carlson's Maxwell left the course, a tire blowout on a steep curve throwing it over a 30-ft. embankment and Franzen, his mechanician, was thrown onto a stump and his back broken, killing him instantly. Carlson was rushed to the hospital with crushed head and internal injuries, but died this morning without recovering consciousness.

The fate of the other cars was as follows: The Schneider special broke a piston in the seventh lap; the Marmon dropped out in the thirtieth with engine trouble; the Parsons special broke a camshaft in the thirty-third circuit, and the Stutz, driven by Lewis, burned out a bearing in the seventy-eighth, while that of Hill broke its radiator in the ninety-first. The Gordon dropped out in the 117th circuit with engine trouble. The Mercedes failed to report to the committee.

New Record for Intercity

Parsons set a new record for the 100-mile Intercity Trophy Race, covering the fifty-four laps in 1:52:27 or at an average speed of 79.5 m.p.h. Elliott, in a Gordon, was only three laps behind him, averaging 74.7, with Barsby third at 63.2, Staley's Studebaker fourth at 56.2 and Erdman's Ford special, fifth. Parsons took the lead second and was never headed, driving a consistent race without a visit to the pit.

Forbes' Buick dropped out in the tenth lap with engine trouble and the Schneider special was forced to retire in the thirty-first. Thomas' Mercer dropped out in the thirty-ninth with engine trouble followed by O'Brien's Stutz in the next lap for the same cause. The Malcom special left the race in the second lap and engine trouble stopped the career of the Tacoma special in the sixteenth circuit. Stratton's Mercer special had engine trouble and its entry was scratched.

Pullen Wins Potlatch Trophy

Pullen won the 200-mile race for the Golden Potlatch Trophy this afternoon covering the 103 laps of the 2-mile course in 2:21:14, making the highest average for the course, 85.2 m.p.h. The Mercer driver outgeneraled Cooper, in the Stutz, who took second place in 2:21:25 or an average of 85 m.p.h. Ruckstell's Mercer was given third place with a timing of 2:31:41, or an average speed of 79 m.p.h., though this was disputed by Oldfield who was officially placed fourth at 2:32:3 or 78.8 m.p.h. Ruckstell had serious engine trouble in the eighty-ninth lap and spent 8 min. at the pits. This is where the mix-up on the time occurred, Oldfield passing Ruckstell on the ninety-third lap without being properly recorded by the scorers.

Out of twenty-one entries but eight started. The 90-mile-gait Mercers soon forced the race, which resolved itself into a battle between Pullen, Cooper, Ruckstell and Oldfield. Pullen went to the pits in the twenty-first lap but made fast time in getting back in the race again and caught Cooper on the twenty-seventh circuit.

Parsons dropped out in the eighth lap with a broken camshaft and the Marmon withdrew in the twelfth with a broken connecting-rod. A slipping clutch eliminated the Gordon in the sixty-fourth circuit, the lap after Lewis' Stutz was put out by engine trouble. Cooper changed a tire in the sixty-sixth lap, this being his only stop at the pits. Oldfield made one stop in the eighty-fifth lap for a tire change.

Burman did not arrive at the course until the ninetieth lap and was refused admittance to the race by the referee. Other entrants were excused on account of engine troubles.

Weather was ideal with a brisk west wind. The track held up well, the new construction rendering better records possible than those of former years, but the officials were disappointed at the low average speed. Attendance was 15,000.

The cash prizes for the two days' racing totaled $10,500. Those for the 250-mile Montamarathon were $5,500; for the 200-mile Potlatch, $3,500, and for the Intercity Century, $1,500. The races were run under the management of the Tacoma Speedway Assn., Inc., and under the auspices of the Mountainview Automobile Club.

Maxwell Averages 91.74 at Omaha

New 1.25-Mile Speedway Opened

Winners at Omaha Speedway

CAR	DRIVER	TIME	M.P.H.
Maxwell	Rickenbacher	3:17:32.2	91.74
Duesenberg	O'Donnell	3:30:27.7	86.16
Maxwell	Orr	3:40:17.3	82.3

OMAHA, NEB., July 5—*Special Telegram*—Before a crowd of 25,000 spectators, the new 1.25-mile board speedway was opened here by a 300-mile race, which was won by Rickenbacher in a Maxwell at an average of 91.74 m.p.h., a speed which demonstrates satisfactorily the possibilities of small board speedways with high banking and which is a higher average than made at Indianapolis this year. Rickenbacher's victory coming right after his winning of the 300-mile speedway race at Sioux City Saturday, naturally stamped him as one of the serious contenders in future speedway events, to-day's race being his third important victory in a year.

Maxwell-Duesenberg Duel

To-day's race here was in every respect a duplicate of Saturday's race in Sioux City in that Rickenbacher led from start to finish and was pursued throughout the entire distance by O'Donnell in the Duesenberg. O'Donnell's average

was much slower, being 86.16 m.p.h. and who, at the finish, was almost 13 min. back of the leader. Orr landed a second Maxwell in third place, averaging 82.3 m.p.h. The only other cars of the eight starters to finish was the Emden, driven by Donaldson, which averaged 62.39 m.p.h. The Du Chesneau driven by Brown was flagged at the finish. This car did not report on the track until after the leaders had covered 100 miles.

Three cars dropped out during the race; Alley's Duesenberg was eliminated at 10 miles with a burned bearing; Cooper's Sebring went out at 95 miles with a burned bearing; and Chandler's Duesenberg was out at 112 miles with cracked cylinders.

The general consensus of opinion with regard to the 1.25-mile board track highly banked, is that this track is faster than the cars, and few of the drivers cared to climb high on the steep banking in order to pass some of the other cars, the drivers fearing that trouble would come if they blew a tire when high on the bank.

The only real excitement in the race was the brushes between Rickenbacher, O'Donnell and Orr, the race so far as leadership was concerned being a procession for Rickenbacher's Maxwell.

Few Stops by Leaders

Rickenbacher stopped twice during the 300 miles, first at 71 miles to change a tire, and second at 226 miles for supplies. O'Donnell's Duesenberg made four stops, losing in all 4 min. They were: at 35 miles spark plug trouble, at 186 miles for gasoline and oil, at 192 miles for tires, and at 215 miles for spark plug trouble. Orr, who finished third, had three stops with his Maxwell, 26 miles mechanical trouble, 105 miles tires, and 272 miles for fuel.

The day was exceedingly hot and the track was feared to some extent. The drivers expected trouble on the high-banked turns. Between 150 and 200 miles O'Donnell slid down the bank for some unknown reason and almost turned his car over when it hit the soft dirt at the bottom. He was delayed only a few seconds. In order to pass a car driving in the center of the track on the turns it was necessary to travel close to 100 m.p.h. Rickenbacher was not pushed and when he had a four-lap lead was flagged and drove easily to the finish.

Rickenbacher started into the lead at 12:40 when Starter Fred J. Wagner sent the cars away. During the first 25 miles there was a merry chase between Rickenbacher, O'Donnell, Chandler and Orr and at one time it looked as if Chandler might take the lead and hold it. The Maxwell was too fast and the driver too daring and at 25 miles the order above was maintained, the average speed being 98, time 15 minutes 18 seconds.

Maxwell Gets in Lead

O'Donnell stopped at 40 miles and Chandler at 42, which gave Rickenbacher a lead of four laps of the 1.25-mile board track. He still led at 50 miles, time 30 min. 46 sec. With this lead he slowed down during the next 25 miles and at 75 led with an average of 97.5.

Maxwell Takes Century Money

O'Donnell and Rickenbacher made things interesting at this time, each trying hard to lead at 100 miles to capture the $250 prize offered. Rickenbacher succeeded in 1:05:28, an average of 91.65 m.p.h.

The order at 100 miles was Rickenbacher, O'Donnell, Orr, J. Cooper, Donaldson, Chandler and W. Brown, who had just come on the track. The same order maintained up to 200 miles except Cooper dropped out. Rickenbacher took another $250 for leading at 200 miles; time 2 hr., 10 min., 44 sec., average 91.79. At this stage Rickenbacher was ten laps ahead of O'Donnell, who stopped at 190 miles for a tire.

The order at 200 and 250 miles was the same as at 100; except that Chandler was out after having worked on his car for 1 hr. replacing a burned connecting-rod bearing. Time for the 200 miles was 2 hr., 44 min., 52 sec., the average speed being 90.98 m.p.h. The same order was maintained at the finish with Rickenbacher about ten laps ahead of O'Donnell.

Cord Tires Lead

Rickenbacher's Maxwell used the same equipment at Sioux City on Saturday, excepting Silvertown cord tires. O'Donnell's Duesenberg also changed to Silvertown cords and used Rajah plugs. Orr's Maxwell's equipment differed from Sioux City in that it used Silvertown cords and Zenith carbureter. The other cars used practically the same equipment as at Sioux City excepting Silvertown on all but the Du Chesneau. The cord tires gave a good account of themselves to-day, only four being changed during the race, these being by Rickenbacher, O'Donnell, Orr and Donaldson.

New Magneto Industry Started in France

(*Continued from page* 52)

which was largely responsible for the great increase in electric lighting and starting sets on French cars at the 1912 Paris show.

Thirty Automobile Firms Unite

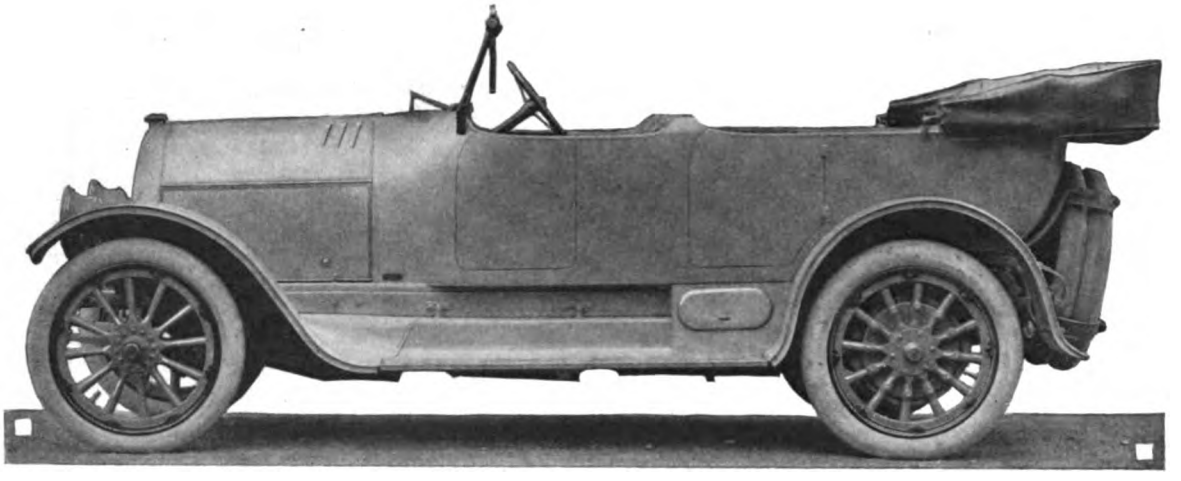
From $160,000 the capital of this company was increased to $400,000 as soon as it was decided to build magnetos on a big scale. A circular was sent to every automobile manufacturer in France, every aeroplane maker, every gas engine builder, setting forth the intention of the S. E. V. company to take up magneto construction, and inviting those firms to take up stock. It was sought to bring into this magneto company every automobile interest. The result is that instead of the nine firms originally interested in the S. E. V. company, there are more than thirty of the leading automobile manufacturers in the enlarged concern, and their combined car output is equal to three-quarters of the total of the French industry.

When the war broke out the S. E. V. company had begun the construction of a big four-story factory at Issy-les-Moulineaux, on the suburbs of Paris. All ordinary building activities had been stopped and will remain suspended until after the war. The building was finished in shorter time than under normal conditions. Machinery has been obtained from America and England and has been installed. The new factory began the work of producing S. E. V. magnetos the middle of May. With the opening of that factory France became independent of outside sources for her supply of magnetos.

As soon as peace has been signed, all German factories in France will pass into the hands of their original owners, with, in such cases as the Bosch company, a rental for their use. The German firms will be free to do business. "So far as our firm is concerned," declared the head of one of the leading French automobile factories in conversation with the writer, "we are through with German supplies." If they were questioned, such firms as Renault, Panhard, Delaunay-Belleville, Mors, Peugeot, Delahaye, Darracq, Bayard-Clement Charron, De Dion Bouton, and a score of others would make the same reply. French manufacturers are determined that the commercial war against Germany shall be as relentless as the war waged with fire and sword.

1916 Fiat Bodies of Distinctive Design

Riviera Is a Combination Five-Passenger Phaeton and Seven-Passenger Touring Car—Few Chassis Changes



The Riviera model 1916 Fiat which is mounted on either the four or six-cylinder chassis

BUT two detail changes have been made in the Fiat chassis built by the Fiat Automobile Co., Poughkeepsie, N. Y., with the introduction of the new model known as the Riviera. The body design, however, is entirely new and is a combination five-passenger phaeton and seven-passenger touring car, of modified streamline and modified double cowl. The two chassis changes are minor ones, being simply a sliding block in the universal at the forward end of the shaft which compensates for longitudinal motion of the rear axle and drive units and the front ball and socket steering connection.

Materials Carefully Selected

It is in the selection of materials that the Fiat is distinctive. One of the points which stands out above all others is in the use of hardened steel bushings against hardened steel pins, at places where only medium heavy duty is required. This applies to such parts as the valve guides, steering connections, etc. Chrome-nickel steel is used in nearly all the important forgings throughout the entire car, examples being the crankshaft, steering parts, gearset parts, and in fact all forgings which have to bear any stress of importance. The valve construction is another example of the careful use of materials being a built-up design with a nickel-steel head, carbon steel stem and a cast-iron seating ring.

Two standard models are manufactered known as type 55, four-cylinder, and 56, six-cylinder. These are identical in every respect with the exception of the motors. The four-cylinder model was added in 1912 and has been continued ever since with only the minor refinements noted. The cylinder dimensions of the four are 5.125 by 6.75 and of the six they are 4.4 by 5.9. Both have block castings and the leading feature of each is the simplicity with which the details of construction have been worked out. Referring to the transverse section, of the four-cylinder motor, illustrated herewith, it will be noted that, although block-cast, considerable waterjacket space has been allowed all around the cylinder castings.

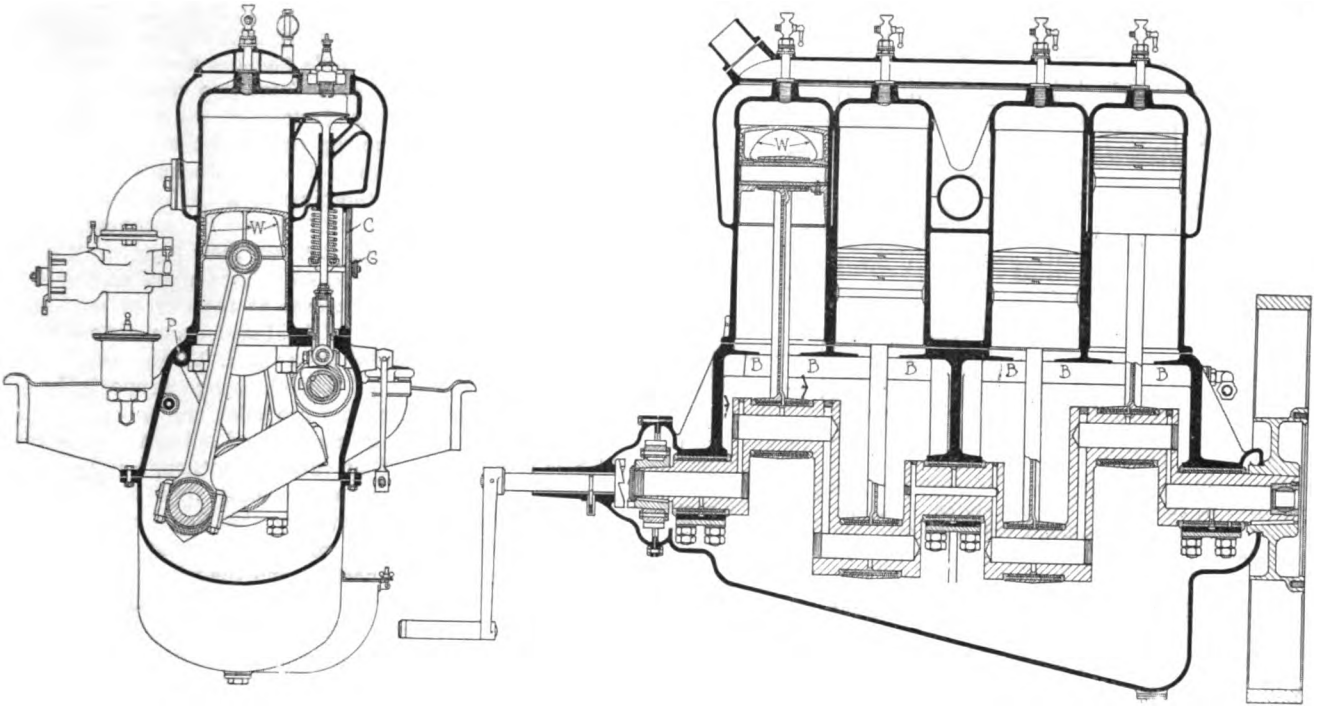
The pistons have four rings at the top and are slightly convex in shape. They are double-webbed across the head as shown at W in the transverse and longitudinal motor sections. The bearing for the piston is formed by a bushing in the upper end of the connecting-rod and this is an interesting point of where steel against steel is used. Naturally, the question of lubrication is of prime importance to avoid any tendency of seizing, and this has been specially guarded against as will be pointed out. The connecting-rods are drop-forged I-beams and the crankshaft in the four-cylinder model is carried on three main bearings. On the six, the crankshaft has four babbitt-lined main bearings.

Actuating the valves, there is a camshaft which has the cams keyed and pinned to it operating directly on a roller follower on the pushrod. This is carried within a steel bushing above which is the adjustment point for allowing clearance below the valve stem. The valve action is covered as shown at C by a substantial plate removable by the knurled nut G. A feature of the valve is that the angle of the seat is 30 degrees in place of the conventional 45, this being done to give a quicker and wider opening, for the same amount of lift.

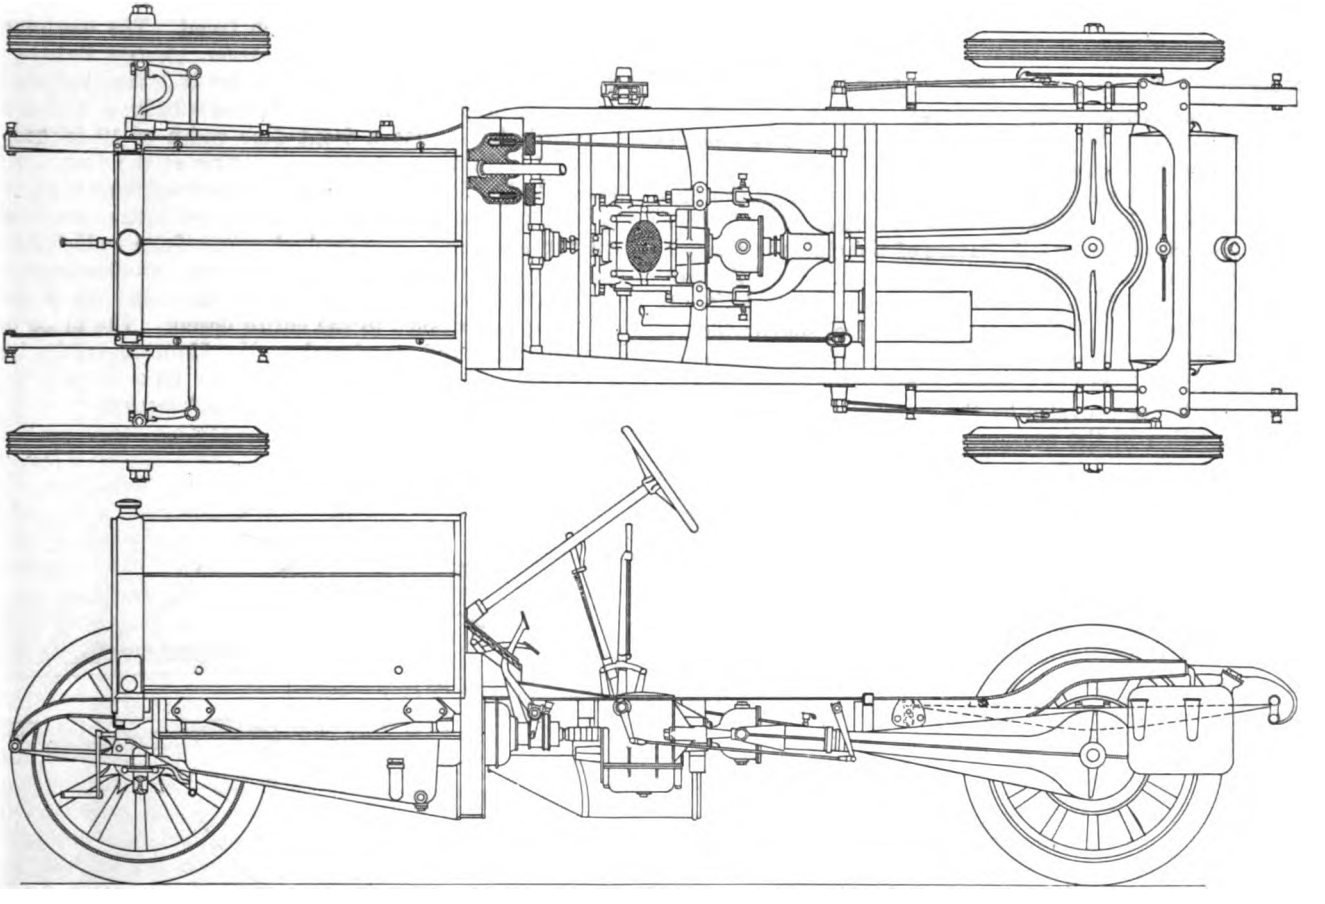
Force-Feed Oiling System

As would be expected with the use of many steel-against-steel parts, the lubrication is force-feed non-splash. The crankshaft is a hollow design both for lightness and to facilitate the pumping of oil through the center. The oil pump is a gear design operated from the rear end of the crankshaft carrying the oil from the reservoir in the bottom of the crank case to a horizontal copper pipe in the case itself. This horizontal pipe extends from one end of the case to the other and is shown in the sectional view at P. From the pipe are leads to each of the main bearings of the motor. The oil passes around the main bearings and entering the hollow crankshaft is forced along its entire length until it reaches the cranks, the cheeks of which are drilled, allowing a passage for the oil to the hollow crankpins. Here the oil under pressure reaches the lower connecting-rod bearings and in addition is forced upwards along a tube to the wristpin bearings which are oiled copiously as required by the steel pins against the steel bushings at this point. An interesting feature is the use of integral baffle plates B which prevent an excess of oil being thrown into the cylinders, thereby caus-

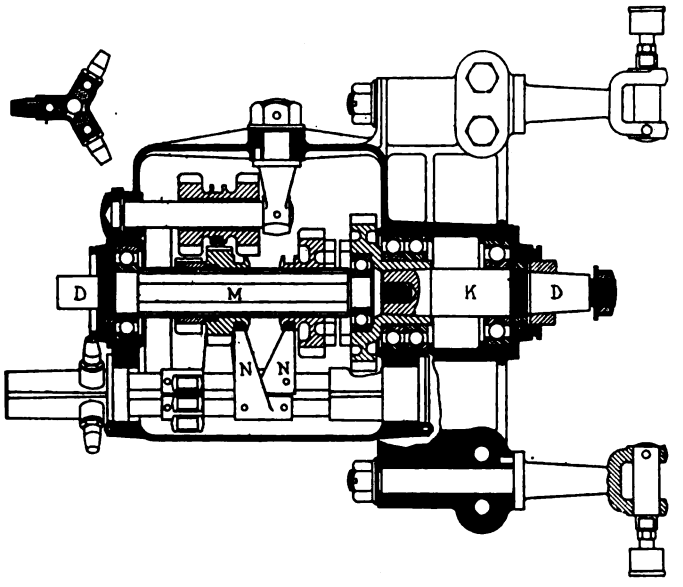
Some Details of 1916 Fiat Chassis



Side and end sections through the four-cylinder Fiat motor for 1916, *showing the use of four piston rings as indicated at W. The valve action is covered as shown at C, the plate being removable by the knurled nut G. P is the horizontal oil lead and in the side section B indicates integral baffle plates preventing excess oil being thrown into the cylinders and thereby causing carbonization and smoke*



Plan and elevation of 1916 *Fiat chassis, showing characteristic rear axle housing and torque tube construction together with the yoke and universal construction at the forward end of the propeller shaft. Detail of this yoke and the section through the gearbox appear on the following page.*



Section through the compact four speed Fiat gearset. The main shaft M connects with the clutch at D and the stub shaft K transmits the drive through the universal joint. Shifter forks are indicated at N

ing carbonization and smoke. The crankcase capacity is 5 gallons.

The water pump and magneto are driven off the opposite ends of a transverse shaft located at the forward end of the motor. The driving shaft for the two units is carried on ball bearings and is driven through spiral gears with teeth at 45 degrees. The entire drive of this shaft is inclosed and runs in a bath of lubricating oil. Flexible couplings are used in the drive.

Sixty-five-Disk Clutch

Sixty-five disks are used in the clutch, thirty-three driving and thirty-two driven. The single clutch spring introduces the pressure on the large amount of bearing surface and the whole engagement runs in oil and is contained in an oil-proof housing. There is a packing box surrounding the centrally located spring container which prevents the oil from leaking from the housing. A feature of the clutch is the provision for alignment by allowing the forward end of the carrier shaft to extend into the rear end of the crankshaft. It is there supported upon a bushing of spherical shape which is held by another bushing supported on threads in the end of the crankshaft. A ball and socket support is thus provided.

Four speeds are provided by the compact gearset which is shown in section in the accompanying illustration. The design is distinctive as the mainshaft M which connects with the clutch at the extremity D extends the length of the gearbox proper, being carried on ball bearings at either end. The stubshaft K at the rear end of the gearbox connects with the universal joint and thence transmits the drive through the propeller shaft. Chrome-nickel steel gears and shafts are used and altogether there are seven rows of ball bearings. A double row is used at the inner end of the short shaft K through which all the power is transmitted. The shaft is four-splined and carries upon it the sliding units actuated by the shifter forks N.

Distinctive Torque Tube

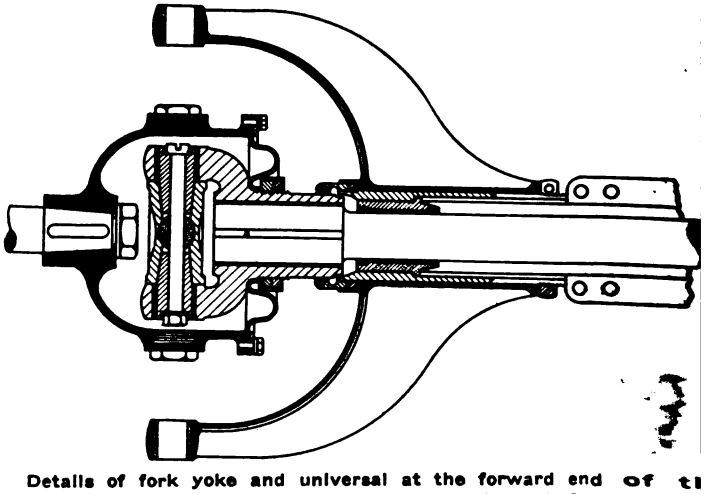
The housing for the gearset is in two parts and is made from an aluminum casting. The mainshaft is carried in the upper half of the housing and the bearings are mounted between the two parts at their junction. The top of the gearbox forms a large cover plate and all connections are milled to form a close juncture and thus prevent oil leaks. Packing boxes are located at the inner end of the main shaft M and at the rear end of the short shaft K. A heavy horizontal web is formed in the gearbox and in this are mounted the trunnion supports for carrying the forked yoke at the forward end of the propulsion tube which surrounds the propeller shaft.

The Fiat rear system is distinctive in the employment of a solid pressed steel rear axle housing and torque tube combined. The housing is made from two stampings manufactured at the Turin, Italy, factory of the Fiat organization. One stamping forms the top half and the other the bottom, and the weight of the two is close to 80 pounds combined. The material used in the stamping is a .50 carbon manganese steel, 4 millimeters or about 1-6-inch in thickness. The two halves are bolted together through their flanges by 5-16-inch cold rolled steel bolts placed 4.5 inches apart on the straight parts of the housing and closer at the curved portions surrounding the differential. The bevel drive differential and the axle shaft are caried on 4 R. I. V. annular ball bearings, and a double set of these bearings support the pinion fitted to the rear end of the propeller shaft.

The ball type steering knuckle and spindle is a refinement which is found in the Fiat cars and although it has been incorporated in both models for some time was not in the original model first put out by the Poughkeepsie concern. The wheels toe in and are so arranged that the center lines through the spindle connection and the wheel intersect at the point where the tire rests upon the ground. The ball and socket joints at the end of the tie rods also aid in providing easy steering and at the same time the car weight is carried on a ball thrust bearing beneath the upper jaw of the knuckle. These parts are lubricated by grease cups and of a design which gives great durability.

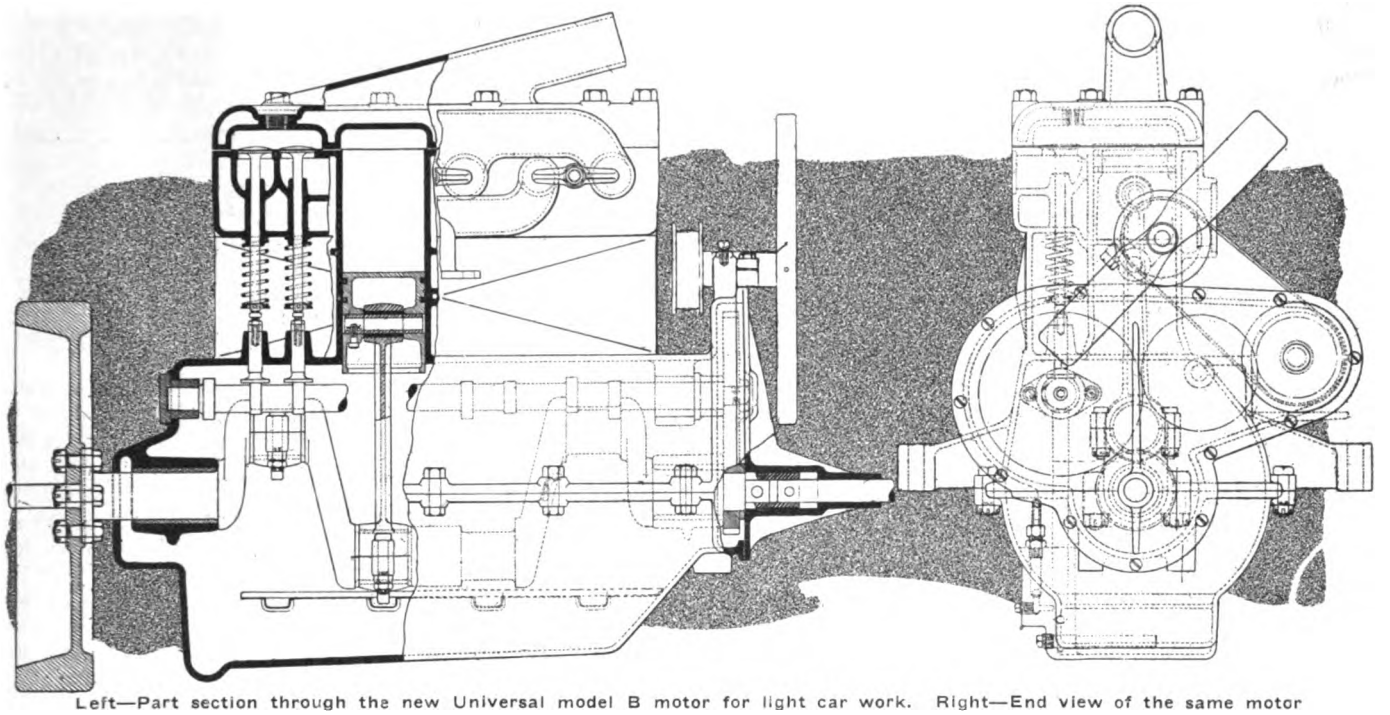
116-Inch Wheelbase

The wheelbases of both the four and six are the same, being 116 inches with standard 56-inch tread. The equipment is complete including Bosch lubrication, electric lighting and starting and a full line of accessories including speedometer, clock, demountable rims, etc. The new body as fitted to the standard chassis has a front door width of 19 inches, rear door, 22 inches, width between tufting at the front seats 43 inches and width of rear seat between tufting of 46 inches. It is a molded design with no abrupt interruption of the contour but made in a gradual sweep from radiator to the end of cowl thence to the secondary cowl sweeping back to the rear end of the tonneau with a gradual slope which lends a low, long appearance to the entire design. The price of the Riviera model fully equipped on the 55 or four-cylinder car is $4,850 f.o.b. Poughkeepsie. On the type 56, six-cylinder chassis, the price is $5,350 f.o.b. Poughkeepsie.



Details of fork yoke and universal at the forward end of the propulsion tube which surrounds the propeller shaft on the 1916 Fiat

Two Universal Motors for Light Cars



Left—Part section through the new Universal model B motor for light car work. Right—End view of the same motor

Model A is 2.5 by 3.5 Inches and Model B 2.625 by 4 —Similar in General Design

TWO motors specially designed for light car work have been brought out by the Universal Motor Co., Oshkosh, Wis. These are known as models A and B and are 2.5 by 3.5 and 2.625 by 4 inches, respectively. The two models are along very similar lines, except for their capacities. Owing to this, the smaller motor is generally used in connection with a 5 to 1 rear axle ratio, whereas the model B takes a 4 to 1. This would give a speed in r.p.m. of 2,400 for the model A at 40 miles per hour with a 5 to 1 ratio. The S. A. E. ratings are respectively 10 and 11 horsepower.

In general design, these motors are four-cylinder, four-cycle, block cast assemblies with three-point suspension. The cylinder heads are removable and carry the water header in a unit. Considering the model B motor, the pistons are a flat head type, fitted with a leak-proof ring and two 3-16-inch rings at the top. The piston pin is case-hardened and the connecting-rod is an I-beam 7.375 inches center-to-center length. The connecting-rod is bushed at the piston end and the pin is secured to the piston boss by a set screw.

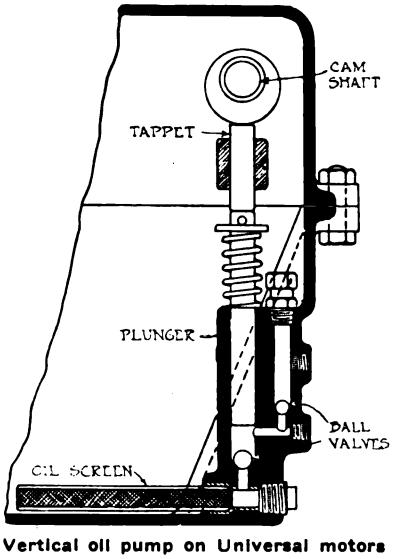
Some Dimensions

The crankshaft is 1.5 inches in diameter forged from medium carbon steel. The crank bearings as well as the main crankshaft bearings are lined with die-cast bearing metal. The crankpins are 1.5 inches in diameter and 1.75 inches in length. The main bearings, of which there are two, are 1.5 inches in diameter and 2.5 inches in length. The camshaft is a one-piece drop-forging with the cams integral and the valves are operated through mushroom valve plungers. The valve diameter is such as to give a 1.125-inch clear opening. The valves have a steel stem with cast-iron head.

Features of the design of both motors are the same, but the dimensions vary. In the smaller motor, the crankshaft is 1.25 inches in diameter, although of the same material as in the larger design. The crankpin diameter is 1.25 inch with a 1.5-inch point and the bearings are 1.25 by 2.375 inches.

Vertical Oil Pump

One of the features of the Universal motors is the vertical oil pump which has the plunger extending downward into the crankcase oil reservoir so deeply that there is no chance of its losing suction. This detail provides a safety feature as the pump need never be primed. All the Universal motors are supplied with a Mayer carbureter and Berling magneto.



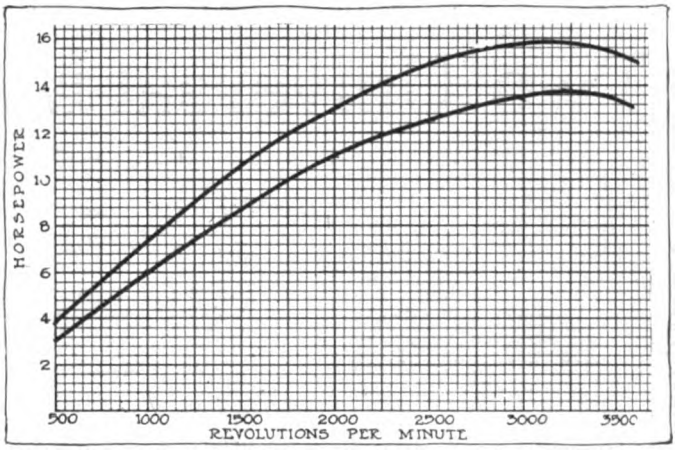
Vertical oil pump on Universal motors which never requires priming

Characteristics Similar.

As shown by the horsepower curves of the models A and B motors, these have about the same characteristics. The peaks of the curve being at 3,000 r.p.m. or more, showing that these are distinctly of high-speed design. The horsepower increase up to 2,500 r.p.m. is quite rapid and the S. A. E. horsepower developed by the model A is about 1,750 r.p.m. while that of model B is about 1,550 r.p.m.

The aim of the designers of these motors has evidently been to follow along the latest lines of high-speed, high-efficiency design. The parts throughout are of light

weight and the curves show a high rotary speed before reaching the peaks. The motors are distinctly designed to serve the needs of the cars for which they are intended, that is, cars of light weight weight and high nominal speed capacity. It is a type of design which should give good fuel economy, provided that the reduction gearing in the power transmission is properly worked out, allowing the motors to work at their best efficiency at what may be called the cruising or touring speeds.



Horsepower curves of model A and model B Universal motors

1,500-Pounder Added to Indiana Line

SPECIFICATIONS of the Indiana 1,500-pound worm-driven truck have been announced by the Harwood-Barley Mfg. Co., Marion, Ind. This truck is largely built in the factory of the Indiana concern, and it includes such features as a block motor, unit power plant, three-speed gearbox and worm drive. The worm-driven rear axle is assembled in the shop of the manufacturer and the Rutenber Motor Co. builds a special power plant for this chassis under the name of Model 20.

Three-Point Suspension

Three-point suspension is used for the 3.5 by 5-inch unit power plant, which is located under the hood. The motor is an L-head design with the valves on the left side. Standard design is used throughout the motor, cooling being by centrifugal pump through a finned tube radiator. The carbureter is a Schebler, ignition is by high-tension magneto and lubrication by pressure feed through the main bearings, camshaft and connecting-rod bearings. Splash is also employed for the cylinders and other internal motor parts. Power is transmitted through a multiple disk, dry plate clutch, to a three-speed sliding selective gearbox with shafts mounted on ball bearings. The face width of the gears and the gearset is .875 inch and the gears are of heat treated nickel steel of high tensile strength.

From the gearset, the drive passes through a shaft of alloy steel to the floating rear axle with its worm drive. The worm has a 2.75-inch outside diameter and the gear 2.625 inches outside diameter. The face width of the gear is 2.25 inches. The worm is mounted on S. K. F. imported annular and thrust bearings. The gear is mounted on New Departure ball bearings. A generous use of alloy steel is made in the drive members, the live shaft of the axle being 1 and 9-16 inches in diameter and of chrome-nickel steel. The housing is a steel casting and the inside diameter of the axle is 2 5-16 inches. The type of worm gear is that known as the Cleveland.

Artillery wheels 36 inches in diameter are employed. Both front and rear wheels have fourteen 1.75-inch spokes. The tires are solid 36 by 3.5 front and 36 by 4 rear. The drive is taken through a torque rod and through alloy steel springs. The front axle is a 2.5 by 1.5-inch I-beam with the spring pads integral. The chain is a channel, 4 inches in depth, weighing 5.25 pounds per running foot. It has three cross members reinforced with gusset plates.

Large Loading Space

A long wheelbase providing great loading space is given on this truck. The wheelbase is 130 inches and the loading space back of the seat is 93 inches long. The tread is a little wider than normal, being 58 inches. Full equipment is sold with the truck, a governor being fitted to limit the motor speed to 1,200 r.p.m. which corresponds to a truck speed of 25 miles per hour on high gear. The gasoline tank is located under the driver's seat and control is central with left drive steering being effected by a Lavigne gear. The price of the chassis is $1,200 and its rated capacity 1,500 to 2,000 pounds.

Throughout the entire design, the needs of the average service required by a 1,500-pound wagon have been kept in mind. The vehicle is especially suitable for the carrying of a large number of small packages of different bulks, and to fill any purpose.

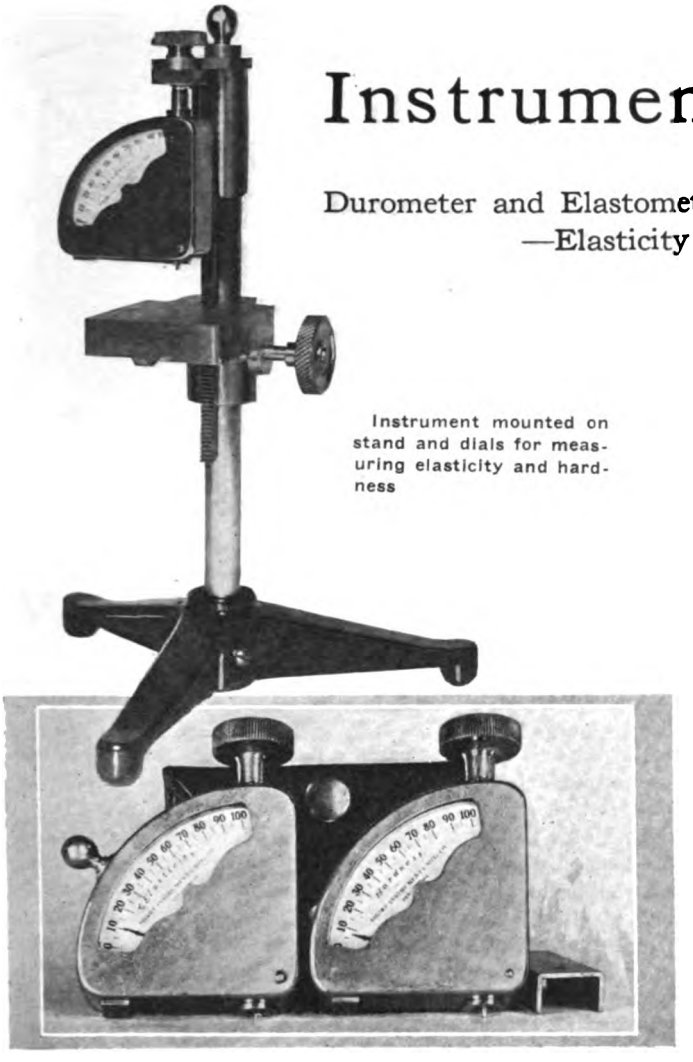
Instruments to Test Rubber

Durometer and Elastometer Measure Relative Hardness and Elasticity —Elasticity Decreases as Hardness Increases



Instrument mounted on stand and dials for measuring elasticity and hardness

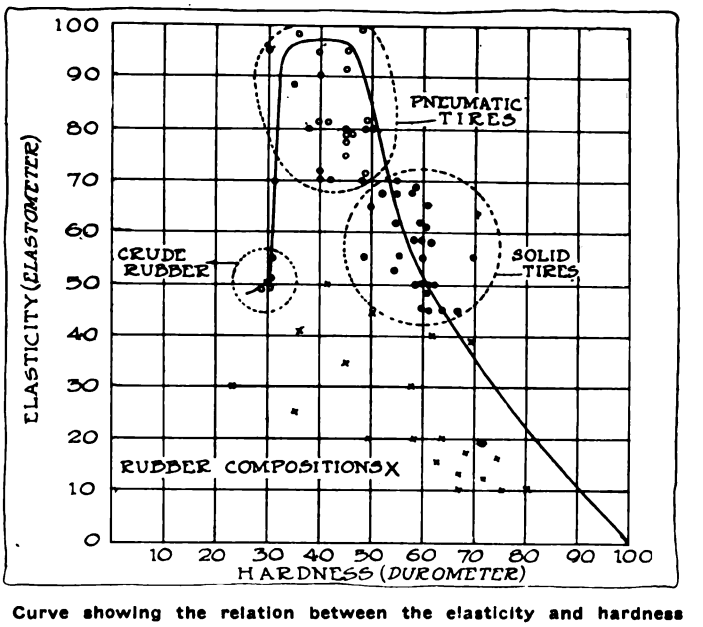
AN interesting example of the manner in which the methods of making tests on metals are spreading to other materials and industries, is that in which types of hardness machines have been adapted for rubber under the names of the durometer and elastometer. These instruments brought out by the Shore Instrument & Mfg. Co. of New York City measure the hardness of rubber in terms of resistance to depression of a plain surface by a standard spring pressing on a blunt pin; and the elasticity in terms of resistance to permanent deformation or tearing. The tests and the difference between them are clearly illustrated at the bottom of this page at *A* and *B*. At *A* the piece is undergoing the test for hardness and as will be noted the material is not torn by the pin. At *B* the test for elasticity is being made and it will be seen the pin enters the material for a considerable distance, effecting a permanent deformation.

The relation of the edge of the point and the depth it has been caused to penetrate has been carefully determined by experiments on extremely elastic rubber. If the latter is quite perfect, no tearing or permanent injury results and the point will be ejected after unlocking it. The extent of the rubber's recovery after imposing this severe stress will then indicate such percentage of elasticity as will correspond with the older form of stretch test. The new test has the advantage of being applicable to the plain surface of finished articles and practically leaves no visible mark.

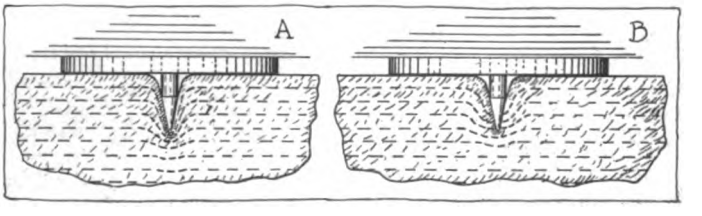
The elastometer is designed for free-hand usage and is put up in a leather pocket case. The durometer is best suited, however, for a stand as shown herewith. The instruments are used principally by manufacturers of rubber, and buyers who desire to test their product. A chart showing the results of test of these instruments and giving comparative data, bringing out the relations between the hardness and elasticity tests, is shown herewith. The importance of the measurement of the hardness and elasticity of the rubber can be well realized when it is noted that when so vulcanized that the maximum elasticity is reached, and when the hardness is yet too low for most purposes, each degree of hardness gained is done so at a sacrifice of about 3 deg. of elasticity. This is clearly brought out in the chart and so persistent is this loss of elasticity that when, for example, solid tires are hardened enough to carry the maximum loads, often so much elasticity is lost that but very little efficiency can be expected.

In the manufacture of rubber goods the process is not under such close control as is the control of metal, for instance, at the present time; but only a few years ago the treatment of metals was very much in the stage that the treatment of rubber is in at the present time. With the ever increasing demand for uniform material, it is aimed to standardize the physical properties of rubber as used in tires.

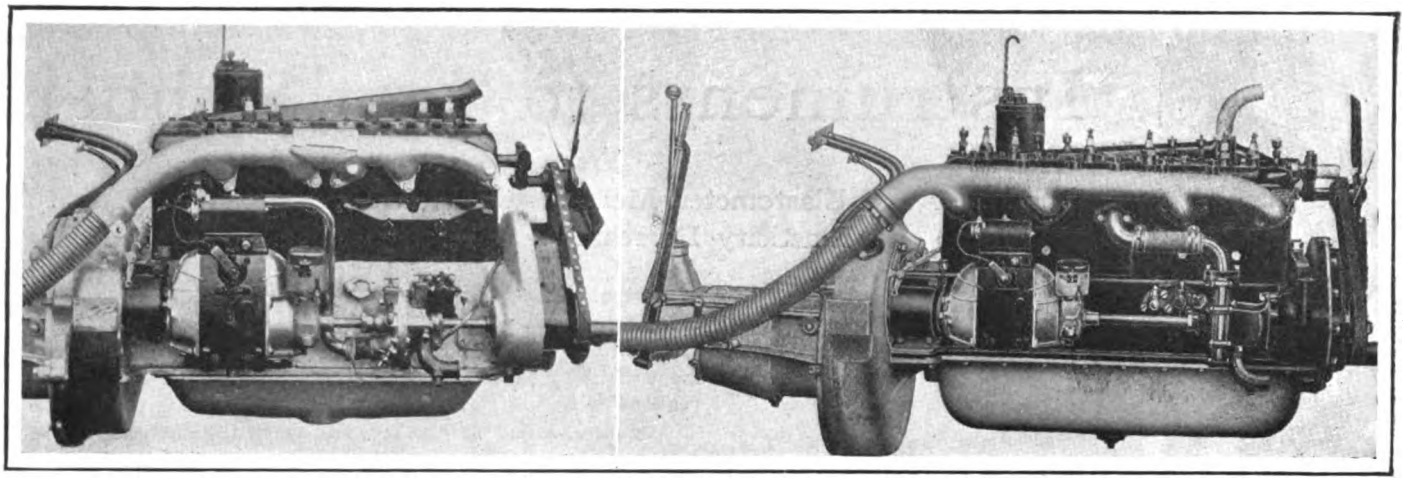
In rubber working a pure raw material does not guarantee the finest finished mattrial when subjected to a given heat treatment. Obviously then, when a fine article is produced, it is not possible to tell without destroying it just what the physical properties are which favor a given result, thus leaving the manufacturer more or less unenlightened.



Curve showing the relation between the elasticity and hardness of rubber



The test for hardness and elasticity, hardness at A and elasticity at B



Two Continental motors used in the Moon six-thirty and six-forty for 1916 showing starter mountings

Two Moon Sixes for 1916—One New

Larger Model Refined and Continued

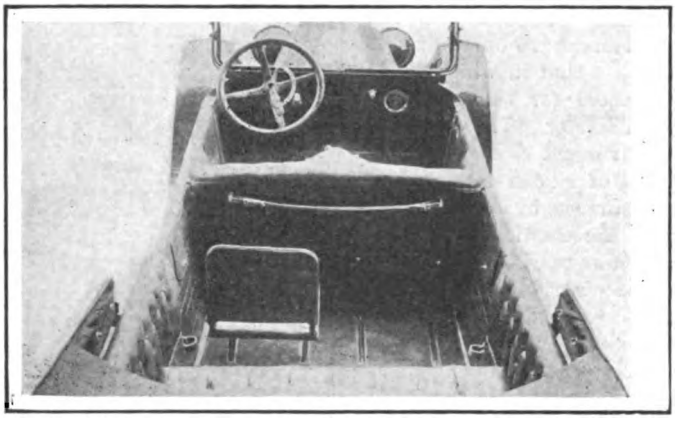
TWO sixes will make up the Moon line for 1916. One, known as the six-forty, is a continuation from last season with a number of refinements and a price reduction of $125. The other known as the six-thirty, is an entirely new model somewhat smaller than the six-forty.

The new features on the Moon model six-forty include a longer wheelbase, that dimension now being 125 inches instead of 123, a new body with the popular tumble-home design which is 2 in. wider across the rear seat and has 1 in. more leg room and 1 in. more tonneau room. These increases in space take up the 2-in. difference in wheelbase. The rear springs are longer and a new Delco starter with ammeter and combination switch on the dash has been fitted. The rear axle now has spiral-bevel drive instead of straight bevel and the equipment is improved by the addition of a motor-driven horn, non-skid tires on the rear and Spanish leather.

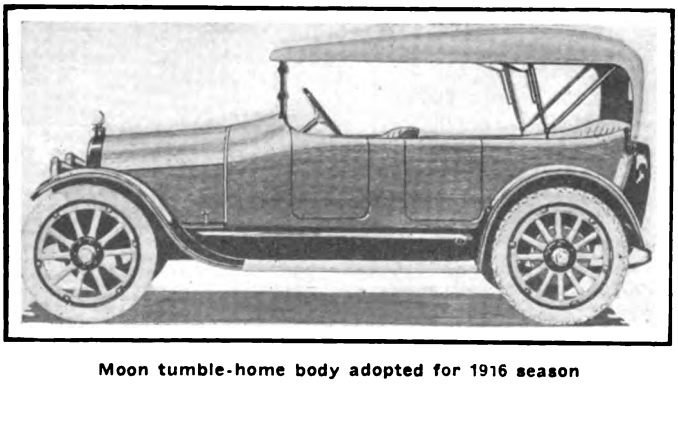
The new six-thirty sells for $1,195 and is fitted with a six-cylinder 3¼ by 4½ Continental motor with the cylinders cast in a single block. The important features of the chassis are similar to the six-forty in design although the price of this car is less than any previously produced by the Moon company. This new model is mounted on a 118-in. wheelbase, is equipped with Delco lighting and starting, has a five-passenger tumble-home body, 33 by 4 in. tires, Hotchkiss drive and full-floating axle. In exterior appearance the two models are quite similar, this being brought about by the fact that the fenders, hood, windshield and tank are identical in the two cars, one being a five-passenger and the other a seven-passenger with the relative power and dimensions proportioned.

The motor in the six-thirty differs slightly from previous Continental practice. The top half of the cylinders is removable, making a detachable cylinder head. The Delco starting outfit is built directly on the motor giving a rigid mounting for this unit and the bell housing for the clutch is a unit with the crankcase, giving a compact power plant with three-point suspension. The clutch is a dry-plate disk, the gearset a three-speed nickel-steel gear design carried on annular bearings and the rear axles floating on annular bearings carried in a pressed steel housing.

The six-forty which has been considerably modified in detail has also the Continental motor employed for 1915, its dimensions being 3½ by 5 and being fitted with Delco starting, Rayfield carbureter, Stewart vacuum feed and unit power plant crankcase with bell housing integral. Both the crankshaft and camshaft in these motors have three bearings, these bearings being contained in the upper part of the crankcase, while the lower part of the crankcase is sealed by a pressed steel oil pan. The 15-in. flywheel bolts solidly to a flange on the crankshaft. The Delco combination, ignition, starting and lighting unit is mounted on the right side of the motor and the makers claim that the starter cranks the motor at 125 r.p.m. The entire electrical system is operated at 6 volts and the battery is carried on a frame under the floor board.



Disappearing seats used in Moon seven-passenger



Moon tumble-home body adopted for 1916 season

Trends in Touring Body Designs

Three Typical Designs on Different Wheelbases Illustrated—Other Necessary Body Details

By George J. Mercer

THE touring body still retains its place as the most popular of body types for general purposes, it is used in larger quantities than other models because it comes nearer meeting all the requirements of an every-man's car and when made in quantities it can be produced at a moderate price and yet have the smart appearance of the to-order body.

The criticism of the open body is that it does not afford the protection from dust that the all-weather or closed body does, especially is this true of the occupants of the rear seat, who are subjected to the dust raised by the air currents or eddies set in motion by the irregular body side lines. The general adoption of the flush-side, streamline, torpedo body has minimized this trouble and the top serves as a shield both in its up and down positions.

Developing the Body

The name touring body is now applied in this country to the torpedo model, the older form of touring model has entirely disappeared, it survived for a time in a modified form by having the fore doors added, but is now seldom seen. The progressive steps in body development have been accompanied by very material changes in the car itself: The engine hoods are now part of the body line; the running boards and frame are lower; the dash lamps have nearly disappeared; the radiator lines have been modified; the running board shield has a blended surface from the board to the body line, the guards have easy lines and the removal of the gasoline tank from under the front seat, permits of the seat cushions being placed nearer the floor, and left drive with center control affords a better line from the body width to the hood.

The body has been amplified also by better windshields, many of which are slanted back to overcome wind pressure; the tops are mostly the one-man type, that do not require supporting irons on the front seat. The attachment for holding down the top have been improved as well as the place for attaching the side curtains. During the past year, there has been placed on the market, a method of inclosing the body for winter use with removable side windows that can be attached to any car, making it nearly as comfortable as a closed body.

The public interest in style is in the present and near-future modes and the three illustrations herewith, illustrate the most modern of the conventional types, the illustrations show three bodies of different size and design and on chassis of different length of wheelbase. Two of the controlling features in a body design are the capacity required in the body and the space provided on the chassis. Of the various dimensions required to show the chassis space, the most important is that from the back of the dash to the center of the rear wheel. The wheelbase of a car is misleading when applied with reference to body space, because two cars may have the same wheelbase, and if one is a six-cylinder and the other a four, the engine hood of one will be longer than the other and consequently the front wheel of one will be further forward of the dash not less than 6 in. than the other, and the body space of a six will be 6 in. or more inches shorter than a four and yet have the same wheelbase. This is indicated on the designs.

These illustrations serve both to show the design and to carry the dimensions in figures of the most essential sizes on all views, and all three designs have the up-to-date feature of having the top line of the seat inconspicuous. The seat cushions are closer to the floor than formerly, and to have the proper height for the seat back and still maintain the low-looking body, the cushions are tilted toward the rear so that the sitting position is partly a reclining one.

Three Typical Designs

The three designs are shown respectively on chassis with 122-, 132- and 142-in. wheelbases and the seating capacity is for four passengers on one, five on the second and six on the third.

One design has central doors, one has staggered doors and the large body has four doors.

Fig. 1 is the four-passenger body, 122-in. wheelbase chassis, having 32-in. wheels and the gasoline tank placed under the cowl. There are two doors that are placed centrally, one on each side, and the passage to the front seats is by the aisle between them. The front seat is built in from the body side top line and this line is unbroken from the cowl to the rear, terminating in the graduated upward back seat line.

The top edge of the body is rounded over from the outside with about 1-in. radius and the metal panel is fastened to the inner edge of the wood framing, the joining being covered by the trimming, which latter does not appear noticeably above the body line.

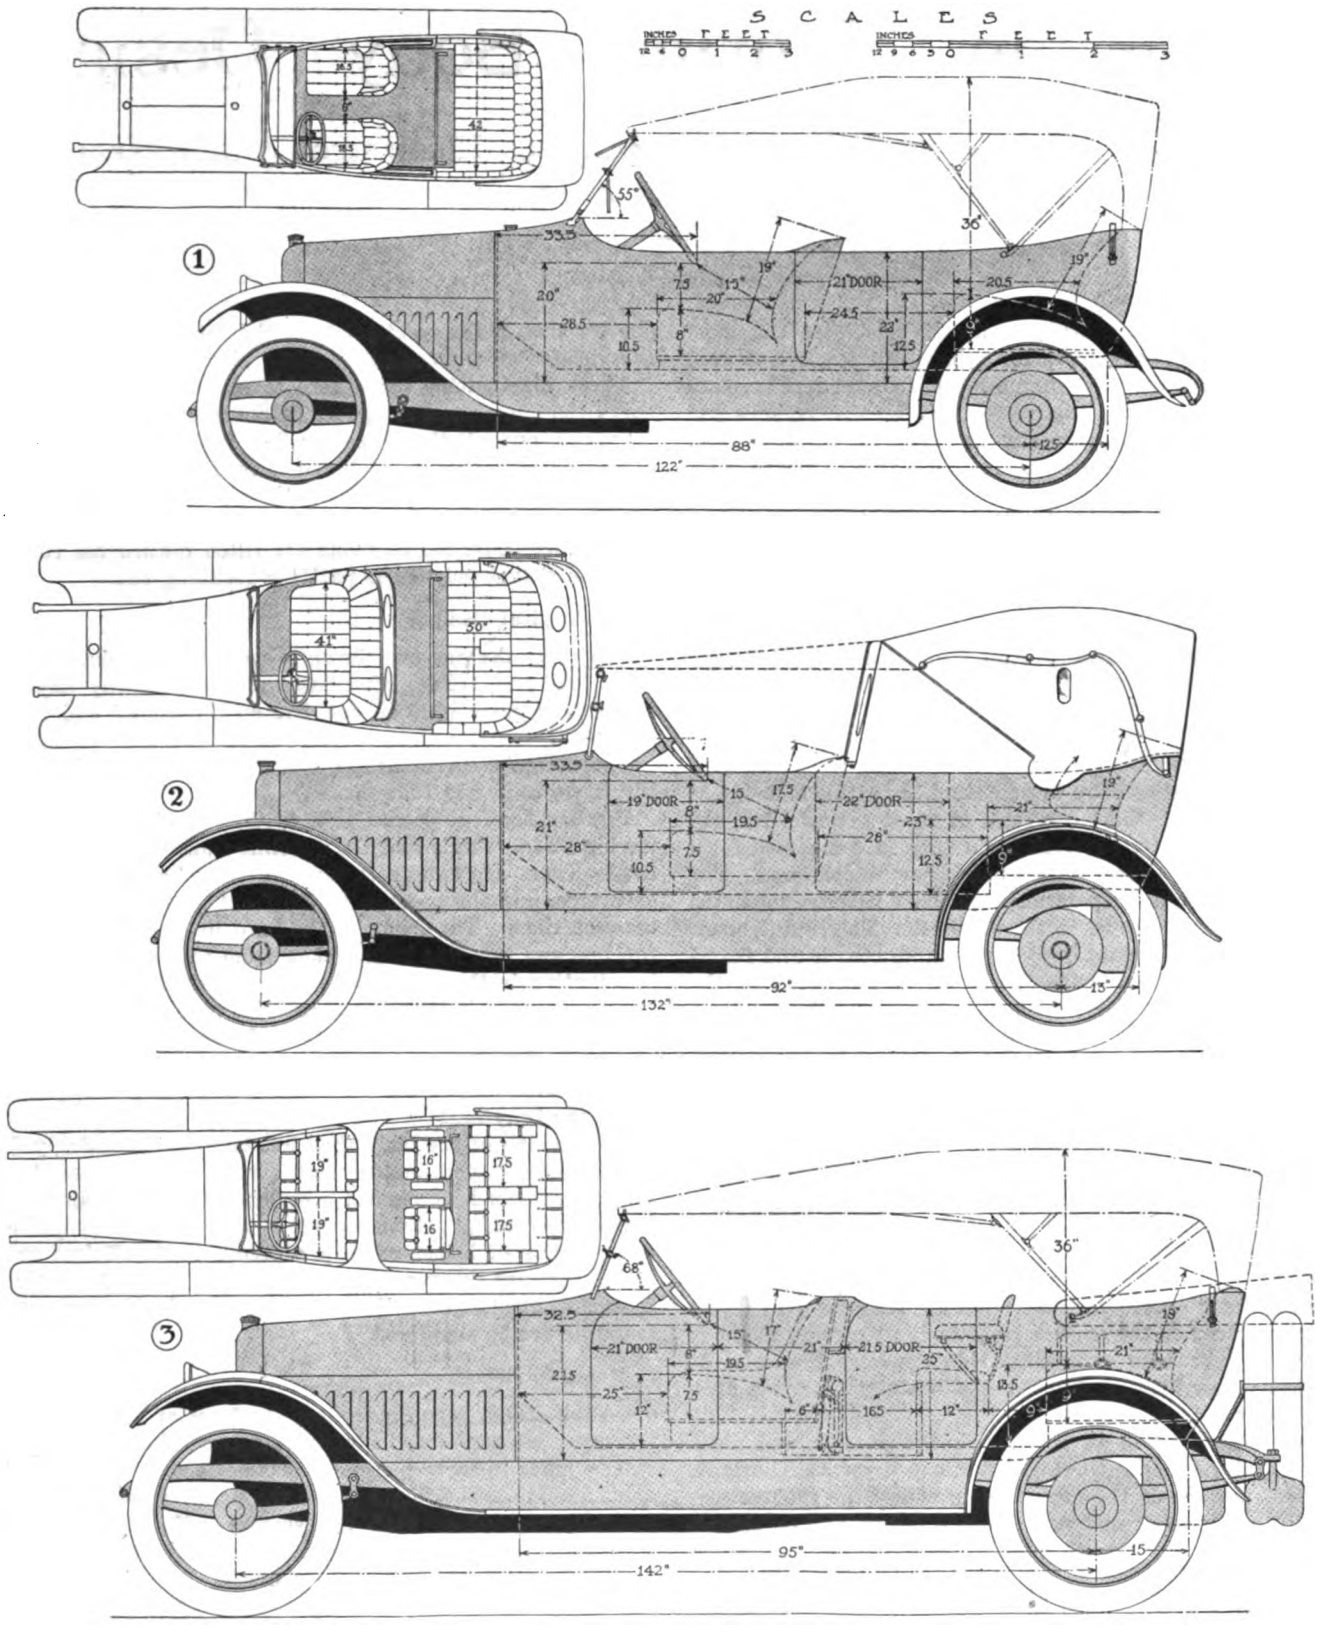
The making of the body shell has become increasingly difficult for the custom builder as the styles have advanced and the accomplished, successful acetylene welding of aluminum panels has come at a time when it is very much needed, where the quantity of bodies to be produced are of sufficient number to warrant the expense of forming the shape in molds or dies, so that steel can be used for the panels, the process of manufacture is simplified.

Features in Design

On the design here illustrated, the front of the body, from the door line forward, including the two sides and the cowl will be made in three pieces, for sake of economy in material and handling. The joints where the panels meet can be successfully welded so that the surface will be perfect for painting and have the strength of a single sheet of metal. The rear panel can be either in one or two pieces and the doors are made without moldings to cover the joints. The entire absence of moldings is one of the characteristics of modern body designing, the influence exerted by the desire to have the unbroken surface for stream line effect has been the principle reason, and, also builders for years have endeavored to have the same outward appearance to a metal body, that a wood panel body presents.

Aluminum or steel may be used for panels according to the facilities of the builder for shaping the metals.

The sides of this body are low, 22 in. only, and the cowl is



1.—Four-passenger body on a 122-in. wheelbase chassis with 32-in. wheels. Two centrally placed doors are used with the front seat built in from the body side top line

2—A five-passenger body on a 132-in. wheelbase chassis with 34-in. wheels. In this design the rear seat is wide enough for three persons and the hinged armrest folds into the trimmingwhen not in use

3—Six-passenger body mounted on a chassis of 142-in. wheelbase with 36-in. wheel. This is a four-door body and the front line is curved to avoid the bent line of the cowl as it meets the side line of the body

1½ in. higher than the rear of the body. The cushions are low and the room in front of the seats is long to compensate. The doors are 21 in. wide and open toward the rear. The steering wheel is well back from the dash and low and the distance from the dash to the center of the rear wheel is 88 in. The body space is 12½ in. more or 100½ in. There is a foot rest for the rear seat as shown on the plan and all the essential dimensions including the tilt of the windshield are indicated. The shield is in two pieces, the lower part shown inclined inwardly to ventilate.

Five-Passenger Design

Fig. 2, shows a five-passenger body mounted on a 132-in. chassis, with 34-in. wheels and the gasoline tank at the rear. The distance from the dash to center of rear wheels is 92 in. and the body space 13 in. more or 105 in. The required dimensions are registered on the two views and are self explanatory.

This design differs from the previous one in that the rear seat is wide enough for three persons and the hinged armrest, folds into the trimming at the back of the seat when not in use and when down, and forms a partition, dividing the seat into two places. Another difference is the style of top, which is a Victoria. The windshield at the rear of the front seat, is high enough to meet the top edge of the front bow of the top and so prevent the wind entering. It carries two celluloid lights and for stormy weather there is an extension, indicated by dotted lines, that is fastened with buttons to the front of the top and to the top of the front windshield. When not needed it is folded away.

The Victoria top adds a pleasing look and when used in conjunction with the shield, as illustrated, the drag effect due to wind pressure is minimized. To obtain satisfactory working results in raising and lowering the top, the covering should be some other material than leather. Leather looks by far the richest, but better knockabout results are obtained with a more flexible goods. Kaki looks well, it does not show the dust and will not crease. The shield can be covered with the same material, and the extension roof and the slip covers can be the same.

The shield is made to be stationary, and is oval shape steel rod. The frame and method of covering are identical with the practice used on carriage dashes. The two studs at the bottom engage the socket irons that project from the back of the seat, and nuts on the under side keep same in place. The celluloid lights are stitched in the same as on the top curtains.

The sides of the body are a trifle higher than Fig. 1, and the increased body width, makes the seating proportions very generous when used for four passengers, but there is ample room for the five when required. The description of the construction is generally applicable for both bodies. The doors are without moldings and the top edge of body side is rounded, the front door opens toward the front and the rear door toward the rear, all hinges and handles being concealed.

A Six-Passenger Body

Fig. 3, is a six-passenger body mounted on a 142-in. wheelbase chassis having 36-in. wheels, gasoline tank at the rear, and the distance from dash to center of rear wheel being 95 in. The body space is 15 in. more or a total of 110 in.

This design has in common with Figs. 1 and 2, doors without moldings and the top edge of body rounded as well as the graduated top line. This line blends into the cowl forming the top of the front seat back. The body sides are higher than Figs. 1 and 2, and under the cowl at the rear, the extra seats are folded when not in use. They are shown in dotted lines in this position, as well as in the position for use. Above the space required for stowing the seats, there is room for small lockers, opening outward in the tonneau.

The dimensions amply located on the two views, show without further description the capacity and size of the body. The doors are four in number and the front line is curved to avoid the bent line of the cowl as it meets the side line of the body. They are made without moldings and open in opposite directions, this is optional, as all doors can open toward the rear if desired.

Upholstery Features

The plan views show two trimming designs. Figs. 1 and 2 have a long pipe caught with buttons and Fig. 3 is a design with the turkish or arm chair upholstery. This latter is the newest style and makes a pleasing looking car and is made thick so that it is very comfortable. The leather for this trimming design must be very pliable and the straps serve the same purpose as the buttons on Figs. 1 and 2. Design 3 has also the advantage of being easily kept clean. Leather is still the most preferable material used for open body trimming, some motor cloth is used and on cheap cars the imitation leather is finding favor and is being used more than formerly.

The principle change made in trimming these styles of bodies, has been the doing away with the roll of trimming that appeared above the side line of the body and seat, in some cases it appears slightly above, but on the majority of new cars it has been lowered out of sight.

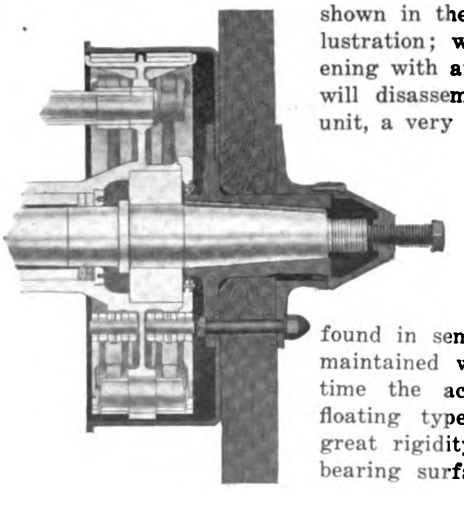
The appointments include the regulation cigar lighter and ash tray and clock, and there are pockets of the doors and robe rail and foot rests, the robe rails are mostly the flexible kind made of a strap and fastened to the rear of the front seat, and the Auster windshield at the rear of the front seat is used more than formerly.

Door handles on this type of body are all inside, and the hinges are both the concealed and the outside curved hinge, linoleum is the best material for floor covering for the toe and foot boards and running boards and leather bound carpet in the tonneau. The top material is either burbank or pantesote and the victoria top goods should be kaki or burbank, preferably kaki. The extra tires are carried at the rear on most cars and the preponderance of color designs are dark shades and blue predominating.

These illustrations are intended to serve the purpose of presenting the design of each model, amplified by dimensions in figures and the description above given is intended to supplement the above two thoughts up to this point only.

Sheldon Semi-Floating Axle

THE Sheldon Axle Co., Wilkes-Barre, Pa., has brought out a semi-floating axle in which the criticism of inaccessibility which has often been leveled at semi-floating axles cannot possibly apply. With this design all that is necessary in removing the wheel from the axle is to insert the bolt as shown in the accompanying illustration; whereupon a tightening with an ordinary wrench will disassemble the complete unit, a very simple operation.



This design is specially applicable to commercial vehicles and with it the excellent bearing surface generally found in semi-floating axles is maintained while at the same time the accessibility of the floating type is secured with great rigidity due to excellent bearing surface.

Communications

¶ The editor of the Rostrum is anxious to secure from car users and others, communications dealing with the overcoming of difficulties in making repairs and in the numberless other phases of every-day automobiling. This department is mutual and is a common ground upon which an interchange of ideas and opinions can be made as freely as in the clubroom.

The Rostrum

Inquiries

¶ The purpose of the Rostrum department is primarily to aid in the solving of motorists' problems. Readers of THE AUTOMOBILE *are requested to allow our editorial staff aid in the solution of difficulties as they arise and perhaps through this assistance reduce the cost of upkeep of their cars and gain a useful knowledge in the economical phases of the vehicles.*

Lengthening Wheelbase Spoils Steering Layout

EDITOR THE AUTOMOBILE:—Will you please advise me if the lengthening of the wheelbase of an automobile 10 in., moving the front axle forward and moving the rear axle back 10 in., will upset the steering layout and if so, how can I correct it? The original wheelbase was 90 in., and is now 110 in. after the change.

Cambridge, Mass. SUBSCRIBER.

—Lengthening the wheelbase throws the steering layout out of arrangement a considerable distance and theoretically prevents the car from turning about a fixed center as it should when the steering gear is correctly laid out. Referring to Fig. 1, the effect of altering the steering of the wheelbase becomes apparent. Assuming a car, wnich in the normal condition has its wheels at AB, the steering layout is so arranged that when the wheels are turned to any position, such as CD, the spindle axes produced should meet at a point E somewhere along the line EF or the axis of the rear axle produced. If the wheelbase is lengthened 10 in., so that the line EF is moved back to E'F' instead of intersecting at a point, the lines of the spindle produced will fall upon the line E'F' at some such point as ee'. Therefore, instead of tending to rotate about one point, the car tends to rotate about two points which is impossible and therefore sliding action results.

Soda for Cleaning Radiator

Editor THE AUTOMOBILE:—Can you tell me how to clean out my radiator? The water here is quite hard and hence scales form. What will remove it? Is it necessary to remove the rubber hose when cleaning? A. J. WHITE.

Schenectady, N. Y.

—Your radiator can be cleaned by the use of ordinary washing soda dissolved in boiling water. To a water pail full of boiling water add a couple of double handfuls of washing soda, forming about a saturated solution. This is poured into the radiator and the car operated for a short time, possibly three or four minutes, to let the soda thoroughly reach all parts of the system. It is followed up by clear water, which rinses out the soda and the matter which is loosened by its cleansing action. If this is done quite frequently, the radiator will be kept free of scale. It is not necessary to remove the rubber hose connections in doing this, as, in fact, the motor must be run in order to thoroughly reach every part of the circulating system with the soda solution.

Seems to Have Carbureter Trouble

Editor THE AUTOMOBILE:—I seem to have much trouble in starting my 1912 model E.M.F. It seems to be the ignition at times. I can start the car by cranking only at certain times, and then again I need only to press on the short circuit button. At other times, I need only to throw the switch over on the magneto and back on the battery to start the car. When it will not start by cranking, it will start by pressing the button, and sometimes, when it is not right to start by pressing the button, it will start by cranking. What would you suggest as a remedy? V. M. C.

Adrian, N. D.

—Going over the symptoms of your trouble, it would seem that it might be due to any one of four causes. These are, 1, gasoline line to carbureter clogged or float valve stuck; 2, water in gasoline, try cock on carbureter and tank; 3, carbureter adjustment too lean for starting purposes, and 4, improper carbureter dash adjustment. This should be set to choke air from the carbureter.

All of these are obvious and can be remedied readily except the last. In view of the fact that the carbureter dash adjustment is an improvement for aiding the starting of these motors, and was brought out since the production of these cars, it might be well to fit one of these in order to secure better results with the low-grade fuel at present on the market. The Studebaker parts list gives the following names and prices of the parts which you will need:

1	A-3455, carbureter air valve assembly	$0.25
1	A-3461, carbureter air valve adj. screw	.15
1	A-3463, carbureter air valve control assembly	.25
1	A-3464, carbureter air valve seat and lever sub-assembly	.35
1	A-3479, hot air throttle and tube connection wire	.05
1	A-3480, hot air throttle and tube connection assembly	1.00
1	A-6 x 2, carbureter control cotter	.01
	Total	$2.06

The handiest for you to obtain these parts would be from Mr. George Young of La Moure, N. D.

If after going through all the above possible causes, you do not locate your trouble, it is suggested that you examine for air leaks the joints of the carbureter, intake manifold, valve stem and guides and look for porous castings. All these joints should be absolutely air tight. Examine the spark timing and the strength of the spark. See that the valves are properly adjusted and seated or, in other words, that the compression is good and then see that all wiring connections are tight.

If you have gone over all the above carefully, there is no doubt but that you will locate your trouble. In inspecting for wiring difficulties you should begin at the switch, carefully examining the switch bars to make sure that a good, clean contact is being made between the segments. Also trace all wires leading from the coil to see that there are none broken beneath their insulation, or the insulation worn off, allowing them to come into contact with some metal part of the car, causing a short circuit. The wires should all be securely fastened to their respective terminals. The breakers should be examined and set at 0.025 and the distributer contact should be free from dirt and making a good positive contact. The sparkplugs should be examined for broken insulation, etc., and here also the gaps should be set at 0.025 in. If you find that the trouble is in the coil

or magneto, it would be better not to attempt to repair it yourself, but take this up with the Splitdorf Electrical Co. direct.

Suggests Source of Oiling Trouble

Editor THE AUTOMOBILE:—Noting the trouble of Mr. George F. Tuttle, with a Buick oiling system, as mentioned on page 988 of THE AUTOMOBILE for June 3, will suggest the following as a possible solution.

If oil was put in the reservoir as well as in the crankcase proper and connecting-rod bearings and burned out in ten miles, it was possibly due to pump failure.

When a system of this type is emptied out and refilled, it frequently happens that the pump becomes air-bound and can be started by lifting the discharge check and filling up with oil, noting that the vane is at its maximum height. Drop the check back in place, and the pump will start unless the suction valve is locked.

I failed to read in Mr. Tuttle's remarks any reference to the sight feed, as to whether or not the oil was being circulated.

If he is not sure as to the above, I am of the opinion that pump failure was the cause of his trouble. B.

Baltimore, Md.

Buick 43 Went 55 Miles per Hour

Editor THE AUTOMOBILE:—Would like the following information concerning the Buick 1912 model 43 touring car.

1. Revolutions of motor per minute.
2. Maximum speed of car.
3. Description of connection of clutch with transmission, and also transmission and front end of driveshaft. Can this joint be made so that it will not leak grease? If so, how? H. F. MURRAY.

Brooklyn, N. Y.

—The motor in the Buick model 43 is stated by the makers to develop 50 horsepower at about 1800 r.p.m. With 3.5 to 1 gear ratio and 36 x 4 tires, this would give a car speed of about 55 miles per hour.

2. This is answered under the above reply.

3. The connection between the clutch and the gearset was by means of a square shaft and Oldham coupling, and the connection between the gearset and driveshaft was through a Spicer universal joint, the driving flange of which was fitted to the squared end of the gearset mainshaft. This gearset was designed for the use of steam engine cylinder oil as a lubricant and oil retainers with double grooves and drain-backs into the case were fitted outside the bearings. According to the Buick company, difficulty was never experienced in keeping the cases oiltight, but no doubt heavy grease would eventually clog the oil drains and finally work its way out upon the shaft. The remedy would be, of course, to clean out the casing and to use the lubricant intended for it.

D. D. Buick the Original Designer

Editor THE AUTOMOBILE:—Who designed the first Buick engines, and when was this done?

2. When, and by whom was the Chevrolet engine designed?

3. How often should a storage battery be cleaned and refilled with liquid? H. L. B.

Hughesville, Pa.

—D. D. Buick was the original designer of the Buick type valve-in-head motor. He started to build this motor for stationary and marine purposes in 1902 in Detroit, and the year after he was joined by Walter L. Marr, who is now chief engineer of the Buick Co. Together they developed the Buick two-cylinder motor, which later became quite well known in the model F.

2. The overhead valve motor used in the Chevrolet cars of today was designed by Arthur Mason, of the Mason Motor Co., in 1912. It was perfected and put out on the market in 1913.

3. A storage battery should be tested and filled with pure water without fail once every week in summer and every two weeks in winter.

Using Too Much Fuel Under Load

Editor THE AUTOMOBILE:—I have a model 38 Overland with Remy magneto and Schebler carbureter. This car seems to choke and for some time it has been using considerable fuel on hard pulls or when speeding up to 20 miles an hour or over. When I throw out the clutch it takes several seconds before the engine will race and fire all around. Then it pulls like a tractor for a while. I sent the magneto back to the factory some time ago and I don't think it is at fault. I thought at first that the fuel line was clogged up, but found this was not the cause. Can you tell me what the probable cause of this trouble is? W. E. WADE.

Kenton, Tenn.

—Regarding the possibility of carbureter trouble, the model 38 Overland used at different times Schebler models D, E and L, which were regularly fitted to these cars. This renders it difficult to give exact information, and if you are convinced it is the carbureter it would be well to pick out the model on your motor from Fig. 2, which illustrates these three types. The exact information could then be given without trouble.

With the instrument generally employed in connection with the model 38, use was made of a spring control auxiliary valve. This valve is guided to its seat through the use of a stem on which the valve stood vertically, governing the auxiliary flow of air. When this stem or valve casting became worn to any extent, its action was likely to permit a chatter or side action. This, of course, would affect the density of gas saturation delivered to the motor and would make the motor sluggish at lower speeds. As soon as the motor, however, had maintained such speed as would keep the air valve constantly off its feet, a more uniform mixture was sent through the manifold and a more satisfactory running condition resulted.

The same condition which you have pointed out in your letter can be caused from ill seating or improperly fitting pistons and piston rings. Loss of compression is not noticeably so detrimental to the efficiency of the motor when it is running at higher speeds, and it is possible that the valves have become carbonized to the extent that they need regrinding. It would be a good idea, therefore, to have the

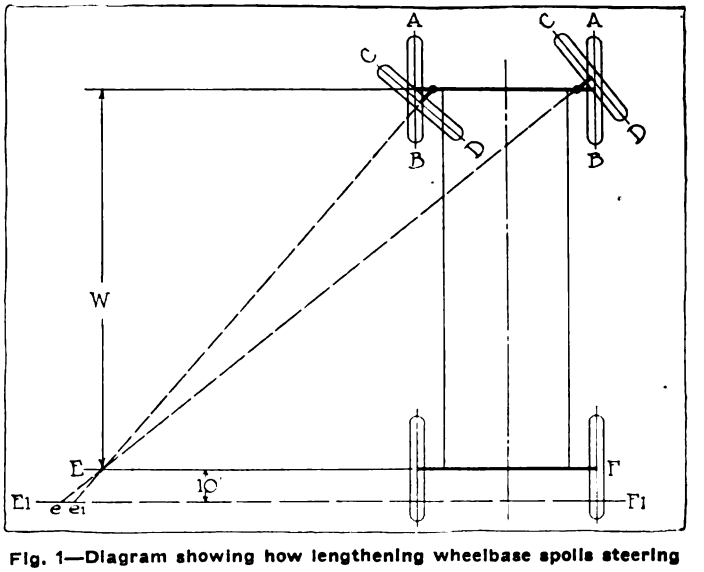


Fig. 1—Diagram showing how lengthening wheelbase spoils steering

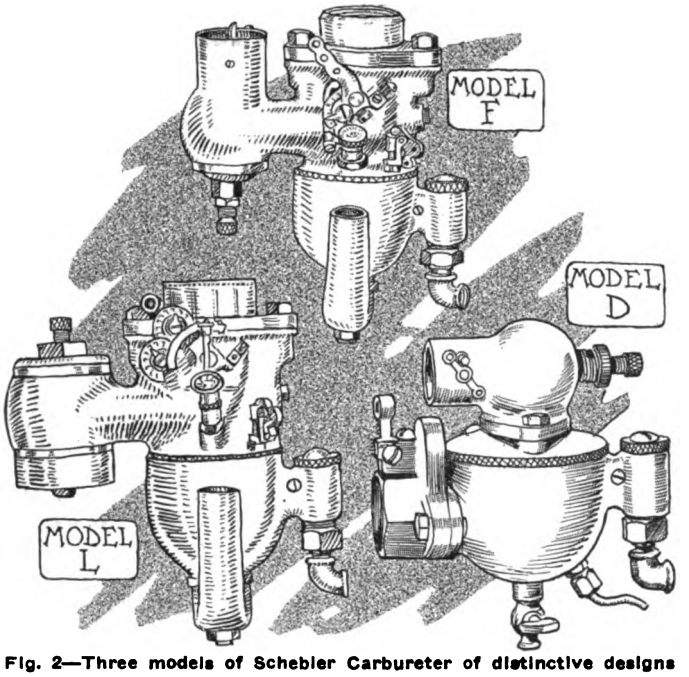

Fig. 2—Three models of Schebler Carbureter of distinctive designs

carbon removed and the valves ground to a firm seat before trying to make any further adjustment of the carbureter. One of the facts which must be realized is that this carbureter was made for a better grade of fuel than that which is at present on the market, and no doubt the heavier fuel which you are compelled to make use of is partially to blame for the trouble.

Ford Branches Equipped for Grinding

Editor THE AUTOMOBILE:—Can you tell me whether the branch plants of the Ford Co. regrind cylinders and fit pistons. What are the costs and can you recommend the nearest branch to me? C. R. ALDRICH, M.D.

Brattleboro, Vt.

—The branches of the Ford company which are equipped to rebore model T cylinders and install 1-32 oversized pistons are the followin:

Atlanta	Dallas	Milwaukee
Buffalo	Fargo	Omaha
Chicago	Houston	Oklahoma City
Cambridge	Indianapolis	Philadelphia
Cleveland	Kansas City	Pittsburgh
Cincinnati	Los Angeles	Portland
Columbus	Long Island City	San Francisco
Detroit	Minneapolis	Seattle
Denver	Memphis	St. Louis

When the cylinder is out of the car there is a labor charge of $3.00 net, covering rebabbitting, reboring and fitting of oversize pistons.

Brattleboro, Vt., is controlled by the Cambridge (Mass.) branch, and cylinders in that territory in need of reboring should be returned to Cambridge.

Gear Ratio of 1915 Oldsmobile

Editor THE AUTOMOBILE:—What is the gear ratio of the 1915 Oldsmobile model 42 on all speeds, low, second and direct?

2—At what engine speed does this car produce its highest power?

3—What is the gear ratio on all speeds of the Overland 81, Hupmobile 1915 model and Buick 27?

4—What make of engine is in the Oldsmobile model 42?

5—Is this motor made by the Northway company?

Eden, Idaho. J. LEVIN.

—The gear reductions of the Oldsmobile on all speeds are as follows:

First speed	13.4 to 1
Second Speed	7.05 to 1
Third speed	4 to 1
Reverse	17.3 to 1

2—The model 42 Oldsmobile gives its maximum horsepower at 1,900 r.p.m.

3—The gear ratios of the Overland 81 are:

First speed	3 to 1
Second speed	1.8 to 1
Third speed	3.9 to 1

Since the rear axle is geared 4 to 1, the final reductions are found by multiplying each of these reductions by 4. The reductions on the Hupmobile models are as follows:

MODEL K

First speed	14.4 to 1 and 15.5 to 1
Second speed	7.20 to 1 and 7.65 to 1
Third speed	4.0 to 1 and 4.25 to 1
Reverse speed	18.31 to 1 and 19.47 to 1

MODEL H AND HA

First speed	16 to 1 and 16.7 to 1
Second speed	8 to 1 and 8.42 to 1
Third speed	3.6 to 1 and 3.86 to 1
Reverse speed	20.34 to 1 and 21.1 to 1

The reductions on the Buick Model 27 are as follows:

First speed	11.76 to 1
Second speed	5.25 to 1
Third speed	3.50 to 1
Reverse	15.12 to 1

4 and 5—The engine is designed by the Oldsmobile company but is manufactured by the Northway Motor & Mfg. Co., which is a part of the General Motors organization.

First Welch Six Built in 1909

Editor THE AUTOMOBILE:—When did the Welch Motor Co., Pontiac, Mich., first produce their first six-cylinder motor?

Detroit, Mich. C. G.

—The first six-cylinder car turned out by the Welch Motor Co. was built in 1909. The car sold for $7,000. A 75-horsepower 4 5-8 by 5 motor was used. The radiator was a honeycomb. Other features of the car were multiple-disk clutch, and 36 by 5-inch tires. The wheelbase was 138 inches and the tread 56. The weight was 4,400 pounds.

How to Pronounce Car Names

Editor THE AUTOMOBILE:—What is the correct pronunciation of the names of the following automobiles: Delage, Mercedes, Chevrolet and Peugeot?

Taylor Ridge, Ill. A SUBSCRIBER.

—The pronunciations of the names given by you are as follows: Delage, Del-ahge; Mercedes, Mer-se-dees; Chevrolet, Shev-ro-lay, and Peugeot, Per-joh.

Liquid Carbon Removers Satisfactory

Editor THE AUTOMOBILE:—Having seen several articles in different magazines concerning the different solutions for removing carbon from motors, and wishing to know if any of these solutions have been tested and found reliable, I would like you to give me the name of any firm or dealer who handles a solution that you know to be reliable? I have never had much faith in these carbon removers because I have been unable to find any one who has tried any of them.

Thiells, N. Y. CHESTER L. ORNE.

—A number of liquid solutions for removing carbon are successful and although they cannot be listed here, any of the brands which have been on the market for some time will probably be found to do all that is claimed for them. They merely act as carbon solvents and therefore are not as quick and positive in their action as scraping or burning carbon from the cylinders. The best way to convince yourself of their efficacy is to scrape some lump carbon from the motor, place it upon a piece of cast iron and put a small portion of the carbon remover upon the carbon and watch the

action. Two points, however, must be watched with great care in using these removers, the first being that they do not attack the metal of the cylinder wall and the second that the lubricating material in the crankcase is not destroyed by the leaking of the carbon remover past the piston. After many of the removers are used, it is necessary to empty the crankcase and refill with new oil, therefore, the best time to remove the carbon is at the time when the oil itself is to be renewed.

Gear Ratios at Different Speeds

Editor THE AUTOMOBILE:—Kindly inform me the gear ratios of the following cars on their different speeds. What I desire is not the final gear reduction between the motor and rear wheels but the actual reduction in the gearbox. Stutz, Mercer, 1914; Mercer 1915; Marmon 41; Simplex and Packard 48.

N. Y. City. SUBSCRIBER.

—These gear ratios are as follows:

MERCER

Series H & O		Series J		Series M	
1st speed..	9.66 to 1	1st speed...	8.58 to 1	1st speed....	10.2 to 1
2d speed...	5.20 to 1	2d speed...	4.62 to 1	2d speed...	5.49 to 1
3d speed...	3.86 to 1	3d speed...	3.47 to 1	3d speed...	4.08 to 1
4th speed..	2.82 to 1	4th speed..	2.52 to 1	4th speed..	3.00 to 1

SIMPLEX 38 AND 50 HORSEPOWER

1st speed	4.03 to 1
2d speed	1.98 to 1
3d speed	1.32 to 1
4th speed	Direct

MARMON 1914 AND 1915 MODEL 41

	1914	1915
Countershaft drive gear	18 teeth	18 teeth
Second speed sliding gear	23 teeth	23 teeth
Low and reverse sliding gear	33 teeth	33 teeth
Countershaft constant mesh gear	33 teeth	33 teeth
Countershaft intermediate gear	28 teeth	27 teeth
Countershaft low speed gear	18 teeth	18 teeth
Countershaft reverse gear	14 teeth	14 teeth
Reverse idler gear	16 teeth	18 teeth

PACKARD MODEL 548

Motor speed at 900 revolutions per minute.
Diameter of rear wheel, 37 inches; circumference 9.686 ft.

With 28-Mile Bevel Gears

First speed, 17/39 x 23/33 x 15/53—.0859 ratio.
Second speed, 26/30 x 23/33 x 15/53—.1709 ratio.
Direct drive, 15/53—.283 ratio.
First speed, 8.5 miles per hour.
Second speed, 16.93 miles per hour.
Direct drive, 28 miles per hour.
Reverse, 8.5 miles per hour.

With 31-Mile Bevel Gears

First speed, 17/39 x 23/33 x 17/54—.0956 ratio.
Second speed, 26/30 x 23/33 x 17/54—.1901 ratio.
Direct, 17/54—.3148 ratio.
First speed, 9.47 miles per hour.
Second speed, 18.83 miles per hour.
Direct drive, 31 miles per hour.
Reverse, 9.47 miles per hour.

The Stutz ratios are not available at the present time.

The gear ratios as given here are in the same order or arrangement as given by the factories of the different companies. It will be noted that some of these are given in terms of total ratio between crankshaft and rear axle and others in reductions in the gearset. In the case of the Marmon, the number of teeth are given and in calculating any desired ratio with these, it must be remembered that the ratio of one gear wheel to another is in direct proportion to the number of teeth.

Wiring Spot Light for a Ford Car

Editor THE AUTOMOBILE:—Will you kindly let me know how to wire a spot light from the Ford magneto and battery? Also size of light to be used?

Buffalo, N. Y. R. KAYSER.

—The wiring of the spotlight from the Ford magneto and battery would require a single lamp of 16 volts or two lamps in series of 8 volts each. One wire would go to the magneto terminal, coming from the top of the gearbox cover and the other wire from any part of the metal on the car. This could not be used in conjunction with the battery as you would only get 6 or 8 volts from a battery which would not light the lamp required by the magneto.

Cid Rotary Valve Motor Still on the Market

PARIS, FRANCE—Editor THE AUTOMOBILE:—In THE AUTOMOBILE for April 1 an article entitled Rotary Valve Makes Slow Progress states that the Itala type of valve is only one now built in Europe, and that the Cid rotary valve motor never has been put on the market. This is not quite correct. The Cid motor was first shown at Paris salon in 1910, and has been on the market ever since. It is still produced at Dijon. This type of motor appears to have given satisfaction, but the output of the firm is not great. The Henriot type, as adopted by Darracq, proved a failure and has long been abandoned, although a determined attempt was made to overcome its inherent defects. The Argyll type of single sleeve motor, although not really a rotary, might be mentioned as produced by the Piccard-Pictet company, in Switzerland. Two of these cars ran in last year's French Grand Prix. The only non-poppet valve motors now built on the Continent of Europe are Knight, Itala, Argyll and Cid. Half the factories of Europe were interested in some type of non-poppet valve motor 2 years ago, but since then interest has dropped to zero. The "valveless" motor is dead as a talking point."—W. F. BRADLEY.

Sheffield Scientific School Maxwell Test

Editor THE AUTOMOBILE:—In THE AUTOMOBILE for May 13 there was a news item regarding an efficiency test on the Maxwell car which was made by the Sheffield Scientific School of Yale University. Would you kindly inform me what kind of tires were used on this test?

Indianapolis, Ind. H. H. K.

—The accompanying is a full report of the test which will give you the information you desire along with the other data secured.

Test at the Mason Laboratory of Mechanical Engineering, Sheffield Scientific School, Yale University

1. Type and model of car—Touring, model 25, 1915.
2. Owner—Biever Motor Car Co., New Haven.
3. Weight with driver—1850 + 150 = 2,000 pounds.
4. Wheelbase—103 inches.
5. Cylinders—Four, 3⅝ x 4½ inches.
6. Gear ratio, direct, measured—3.55 : 1.
7. Tires, size—30 x 3½ inches.
8. Tires, make United States—Chain, inflated to 65 pounds.
9. Carburetor—K. D.
10. Ignition—Sims magneto.
11. Starter—Sims-Huff, electric.
12. Wind resisting area, measured—4.5 x 4.5 = 20 sq. ft.
13. Rolling resistance by dynam.—36 pounds.
14. Gasoline from Mason Lab.—Specific gravity 0.724 at 69 deg.

POWER AND FUEL MEASUREMENTS

Speed, miles, per hour	Drawbar pull, pounds	Horse-power at rear tires	Grade, per cent.	Mileage, miles per gallon	Fuel, pounds per h.p. per hour	
10.2	42	1.2	0	33.8	1.57	level
19.8	60	3.2	0	33.2	1.13	level

				Av. 12.0	Av. 0.89	full load

Tests made April 30, 1915, under direction of E. H. Lockwood and F. Q. Boyer.

Gas Brake vs. Mechanical Friction Brake

Using a motor brake as a service brake is said to economize considerably on wear of solid rubber tires, on the principle of obviating the blocking of wheels. Any similar resistance effected by gases should have the same result and might also be available for regulating the speed of coasting and for otherwise moderating the driving speed more conveniently than by lowest throttling and slipping of the clutch.

ACCESSORIES

Atlas Gasoline Improver on Test

A FLUID for the purpose of increasing the effectiveness of fuel is on the market. It is put up in packages containing five small phials of the material, each phial being sufficient to treat 5 gallons of gasoline. It is claimed that the material will increase the mileage per gallon and also increase the speed for a given throttle opening.

The material is said to be composed of a compressed mixture of hydrogen gas, gasoline and a very small amount of water. The exact composition is a secret, but an analysis shows that it does not contain any of the common constituents used for doctoring fuel. A test by an analytical chemist showed that there was no ethyl ether, picric acid or camphor in the solution. These are the three components which are generally found in so-called fuel improvers.

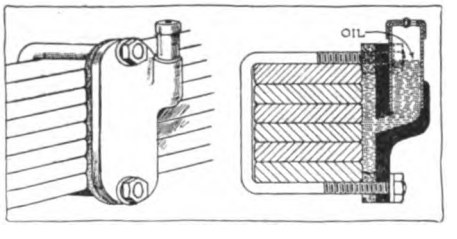
Used by Fire Department

The material is said to be used by the fire department of Chicago for use in patrol work. It has been tested out by others in Chicago during the past 4 or 5 years and at the request of the Eastern distributors the test was made upon the substance by a representative of THE AUTOMOBILE. The run was carried out on a level stretch of road near Coney Island, known as Ocean Parkway. A Ford car was used in the experiment and after the tanks had been drained and the motor allowed to run until it came to a stop a quart of measured untreated fuel was poured in. The throttle opening was fixed to a definite point and locked in this position and the spark also fixed. On the quart of plain gasoline, the car ran 6.5 miles at an average speed of 17.1 miles per hour.

At the completion of the first run after the motor had come to a stop, the car was brought back to the starting point and a quart of the treated gasoline placed in the tanks which were emptied in the same manner as previously. Under the same conditions of spark and throttle setting the distance traveled by the car was 7.3 miles and the average speed 20 miles per hour. This gives a comparative mileage per gallon of 26 with standard gasoline and over 29 with the treated material. Furthermore, the average speed was increased for a corresponding throttle setting approximately 3 miles per hour. The improver sells for 25 cents a package and enough is contained in each package to treat 25 gallons of gasoline. The distance measurements were made with a Jones speedometer which was not checked for accuracy, but since the measurements for both treated and untreated fuel were made with the same speedometer, any differences should offset themselves.—Atlas Gasoline Improver Co., Chicago, Ill.

Leaf Spring Oiler

A leaf spring oiler made in six sizes to fit all size springs has recently been brought out which is said to work the oil between the leaves while the car is operating. The device is so arranged that when oil is placed in the oil cup on the side of the device, as illustrated, it is led down along the sides of the spring and the motion of the spring permits the oil to work its way in between the leaves, keeping them lubricated. The device is also made in another and cheaper style without the oil cup, but with an oil hole. A special set of four of the cheaper style is put up for Ford cars at a price of $1.60. The regular price is 50 cents apiece for the style without the oil cup and 75 cents apiece for the style with the oil cup.—Grus Leaf Spring Oiler Co., Chicago, Ill.



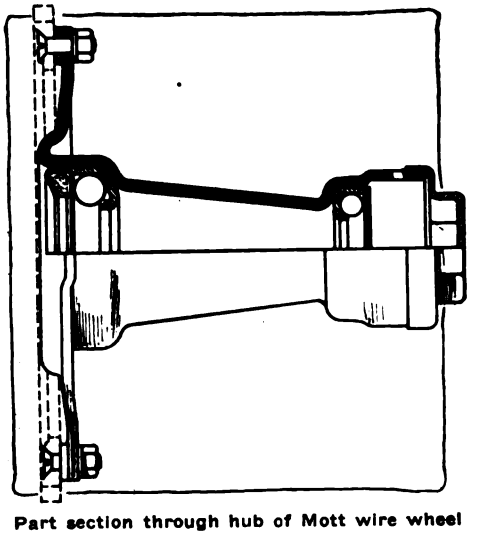
Grus leaf spring oiler clamped against side of spring

Graphonoil Lubricant

A new graphite and oil lubricant has been introduced in which a thin film of graphite is stated to be spread over all the working and bearing parts with which the lubricant comes in contact. The material which is called Graphonoil is stated by the manufacturers to have effected a change in the graphite which makes it mingle with the oil and not be suspended in it. It is stated that with its use there cannot be any precipitation of the graphite and the entire constituency will pass through a mechanical filter. It is claimed not to carbonize and to effect a saving as the feed can be reduced with it.—The Winslow Lubricating Co., Buffalo, N. Y.

Dry Battery Car Lamp

For automobiles without electric lighting sets when a moderate illumination is required now and then for short periods, there is a great deal in favor of dry batteries as a source of current, as they are less trouble to look after than oil lamps. The Wireless Autolight is a well-made case supplied with a lamp and reflector, glazed in white, green or red. It takes a standard No. 6 cell and three lamps complete cost $10.—Peck Engineering and Mfg. Co., Rochester, N. Y.



Part section through hub of Mott wire wheel for Ford cars

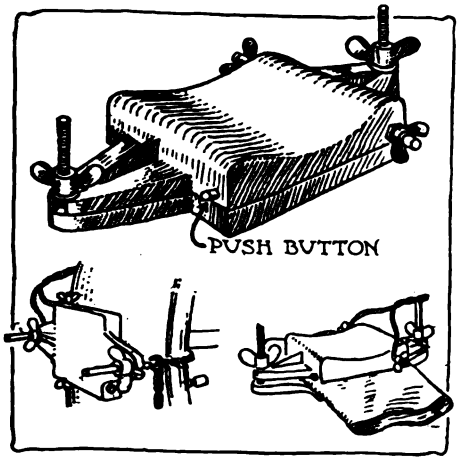
Air Shock Absorber

This device is not a supplementary spring, but a main spring damper. It is attached to the axle and to the frame of the car, the connecting pins being parts of small universal joints so that the action is not interfered with by side sway or irregular action of the main spring. A bronze piston is normally located about the middle of a bronze cylinder, both ends of which are closed. From one end to the other there is a minute passage so that air can pass from top to bottom and *vice versa*, but only quite slowly. Thus when the cars runs over a bump the piston moves down the cylinder and forces air through the by-pass to the upper end, to damp the recoil following the bump, this air has to return to the bottom of the cylinder again, so the absorber is double acting. There is an adjustment which sets the size of the passage and so enables the action to be made easy or stiff according to requirements. Prices vary from $75 up to $120 according to size, per set of four.—Air Shock Absorber Co., Boston, Mass.

Premier Electric Vulcanizer

An electric vulcanizer weighing but 2 pounds is shown in the accompanying illustration. This device operates from

the 6-volt storage battery usually carried in the car and is provided with a thermostat which automatically cuts off the current as soon as the vulcanizer attains the correct heat for vulcanizing the repair on shoe or inner tube. It will take any size tire up to 5 in. diameter. The vulcanizer may be used either in a garage or on the road, being simply clamped to the tube or casing, two wires being connected to the battery and contact applied through a button. The simplicity of operation of the device is said to render it of value in quickly healing up small cuts in casings as soon as discovered, thereby preventing moisture from working in and rotting the fabric. The device sells for $3.50 complete with repair gum and 10 ft. of wire cable.—Premier Electric Co., Chicago, Ill.



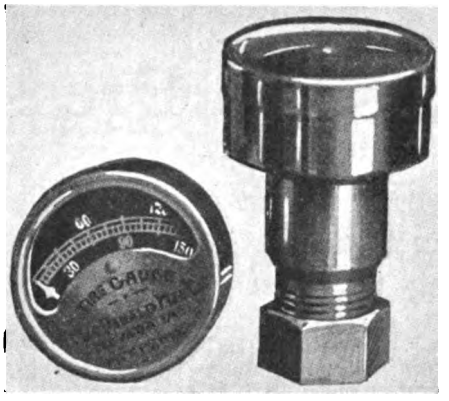
Premier electric vulcanizer at work

Valve Seating—A very complete outfit for repair shops with a wide range of cutter for truing valve seats is among the most interesting New Era products. Described in the same leaflet is a small tool for dealing with the valves themselves.—New Era Spring and Specialty Co., Detroit, Mich.

Automatic Vulcanizer

A vulcanizer which is automatic in that after gasoline enough to saturate a wick has been poured in, no further attention need be paid to it, has recently been put on the market under the name of the Worcester automatic vulcanizer. The principle upon which the device operates is the same as for other gasoline vulcanizers, except that it contains a wick and does not allow the gasoline to remain free in an open chamber.

With the wick arrangement it is possible to apply the vulcanizer to the wheel for work on the casing as the gasoline cannot pour out, while for work on tubes it is used in the same way as other gasoline vulcanizers. In operating the vulcanizer, on a casing the cut is cleaned as much as possible with sand or emery paper and washed with gasoline enough uncured rubber to make a smooth surface is added and cleaned with gasoline after



MacDonald's tire gage valve-cap

which it is applied to the casing and the vulcanizer applied with a piece of paper between the metal of the vulcanizer and the prepared rubber. The asbestos working is unsaturated with gasoline and ignited and allowed to burn until the flame goes out. After this the vulcanizer is allowed to remain in place for 5 min.

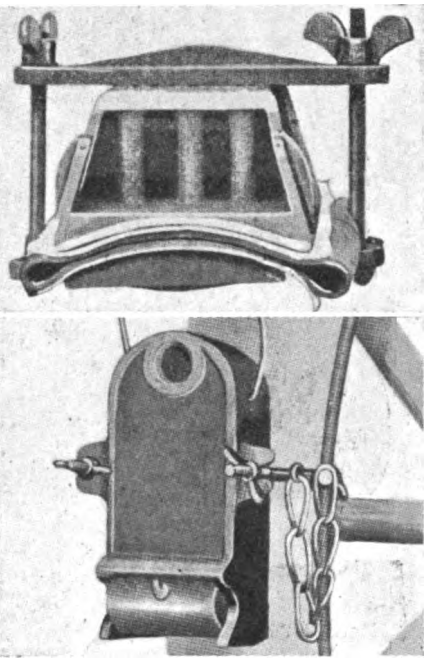
For inner tubes the same process applies, only enough rubber being used to cover the puncture. The heat radiated through the vulcanizer due to the burning of gasoline has been gauged to maintain the vulcanizer at the proper temperature. The vulcanizer weighs 4.5 lb. and its price is $3.50 f.o.b. Worcester.—Worcester Mfg. Co., Worcester, Mass.

Ford Wire Wheels

Those who wish to fit their Ford with a set of wire wheels can do so very easily with the set supplied by the Mott company, as these can be put on without any alterations to the axles. It is necessary merely to remove the old wheels, clean the axle ends and put the wire set in place. The Mott wheel has a demountable rim and one spare is included with the outfit. The drawing shows the fitting of a front wheel, the ball cups and balls coming with the wheel. Special lugs are provided on the right front wheel for the attachment of the speedometer drive. The change can be quickly made by an amateur without trouble.—Mott Wheel Works, Utica, N. Y.

MacDonald's Tire Gage

A valve cap which is a perpetual pressure indicator has been brought out recently and should merit the attention of owners who desire to keep a careful check on the inflation pressures of their tires. This gage displaces the ordinary cap and acts itself as an air seal. With this tire gage leaky valves are eliminated because the valve itself is held wide open by the gage cap and the gage itself is air tight. The device is shown in the accompanying illustration and as will be noted, has a dial which at all times indicates the pressure in the tire. The price for a set of four of these is $6.50.—J. F. MacDonald Mfg. Co., Nevada, Iowa.



Worcester automatic vulcanizer for tubes and casings

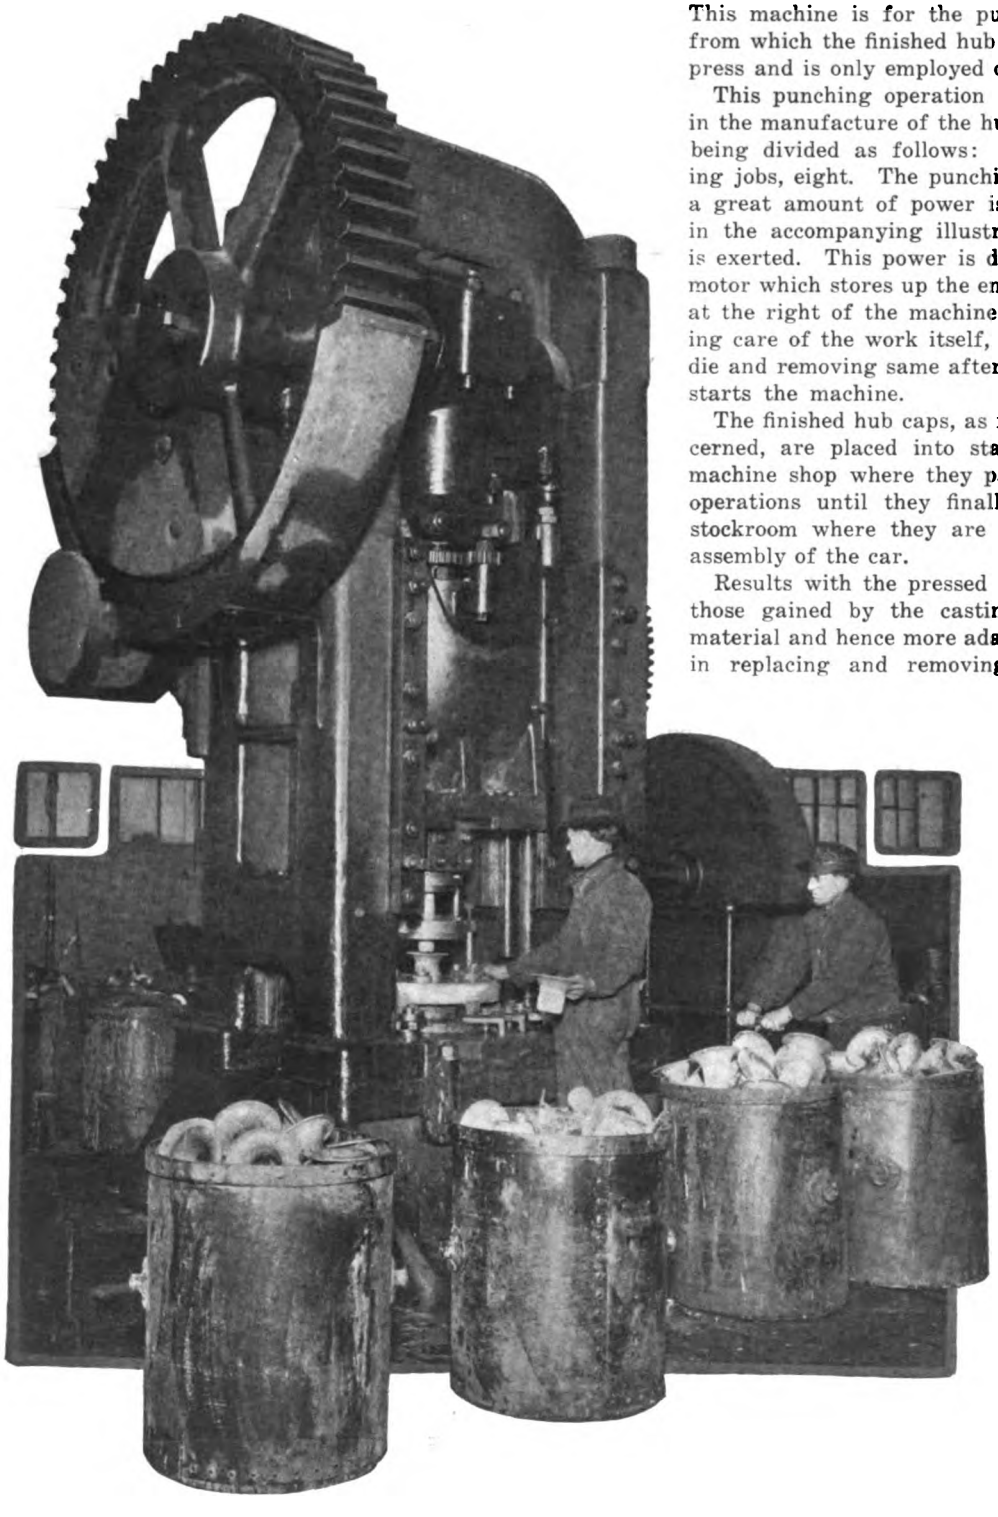
Peck dry battery lamp for automobiles

Dodge Uses 750-Ton Press for Hub Caps

Seventeen Operations to Complete a Hub Cap—Big Press Makes 2,500 Stampings a Day or More Than Four a Minute—Pressed Cap Said to Be Superior to Cast Owing to Finer Grain of the Resulting Metal

Illustrating the large press used by the Dodge Bros. In turning out the stampings from which the finished hub caps are made for the Dodge cars. Note the standard shop cans in which the finished stampings are placed after they are removed from the machine



SEVENTEEN operations are necessary to complete the work on a hub cap, and in order to cut the time to the limit on this work the Dodge Bros. have installed a machine in their Detroit plant which has a capacity of 2,500 hub caps a day. This machine is for the purpose of forming the rough shape from which the finished hub caps are made. It is a huge punch press and is only employed on the hub cap for the front wheels.

This punching operation is the only punching job necessary in the manufacture of the hub caps, the other sixteen operations being divided as follows: Drawing operations, eight; machining jobs, eight. The punching work is, of course, one in which a great amount of power is required and on the press shown in the accompanying illustration a pressure of over 750 tons is exerted. This power is derived from an independent electric motor which stores up the energy in an enormous flywheel shown at the right of the machine. The men work in pairs, one taking care of the work itself, that is, placing the stock under the die and removing same after pressing, while the other stops and starts the machine.

The finished hub caps, as far as the pressing operation is concerned, are placed into standard cans and forwarded to the machine shop where they pass through a series of progressive operations until they finally make their way into the parts stockroom where they are drawn upon for work in the final assembly of the car.

Results with the pressed hub cap are much better than with those gained by the casting method, being of finer grained material and hence more adaptable to the stresses put upon them in replacing and removing. With this large machine 250 stampings can be made every hour. This is, therefore, an operation in which the skill of the workman, in placing the raw material under the die and removing it quickly while inserting the next, is of great importance. The illustration shows the continuity of the work, the operator placing one stamping into the cans while the next one is undergoing the operation by the die. The speed at which this work is done can be realized when it is known that the machine turns out more than four a minute. The actual operation including the time of stopping and starting the machine taking less than 15 seconds for each stamping.

The cans into which the finished stampings are placed can be readily transported from the punch press to the machines upon which the other operations are performed. They can be placed upon small hand trucks with but little effort and wheeled into position.

The Service Convention

SCARCELY anything in connection with the automobile industry has been more abused than the term service, with the possible exception of salesmen trying to sell cars entirely on high-gear performances on hills. The high-gear evil is pretty strongly entrenched, so is the service one, but the meeting of service managers for two days last week points to an early elimination of a few of the more impossible evils of service as interpreted by salesmen and short-sighted dealers, as well as a few injudicious makers.

Makers, dealers and owners are slowly but surely coming to the conclusion that service does not mean giving something for nothing, or, getting something for nothing. The concern building on such a foundation has only troubles ahead. Service has been better defined as making it easier to own and maintain an automobile, not that you get presents from the maker or dealer in the form of free inspections, free adjustments, free replacements, and cuts in your repair bills; but rather service is prompt attention, courteous treatment and accurate workmanship with reasonable charges.

When we travel across the country on a limited train we expect service, but this does not mean getting our ticket at a reduced rate; getting free exchange of an upper for a lower berth; or having a discount on all dining-car meals; rather service, there, means attention when it is needed, prompt dining-room service; clean cars, clean berth linen, traveling on schedule and many other details that go to making your trip easy and pleasant.

In our modern hotels we expect service, service which we unquestionably pay for in the daily hotel rate or in dining-room charges. In this connection service might be defined as getting what we pay for and getting it without asking and having to go to considerable trouble to obtain.

Service managers first have to remove the beam from the eyes of their own selling forces before trying to extract the mote from the eyes of automobile purchasers. The evil has largely started with the seller, not the buyer.

Whither?

WHILE we are talking about finality in design and the complete standardization of automobiles, it is noticeable that there is a growing feeling of doubt among the engineers and the manufacturers who have been responsible for development up to the present time. This questioning attitude was very much apparent on the S. A. E. lake trip even in the tone of general discussion, while it was much more pronounced when a few men talked quietly together.

The truth of the matter is that few manufacturers are quite so satisfied with their cars as they would like to be; they are much less satisfied than they expected to be when looking forward to 1915 from a couple of years ago. Yet just what this lack of content is would be difficult to say in a few words.

Uppermost in the minds of many is the idea so well brought out in the discussion in A. L. Brush's paper dealing with motor design, namely that in obtaining wonderful high-gear performance, by using a large engine and a low gear ratio, the correlative disadvantages of rapid wear of motor parts and poor economy of fuel have been introduced. That the American public demands so much greater high-gear power than the user of cars in any other country is largely the fault of the manufacturers, who have for many years done almost all they could to discourage gear shifting. It seems that some of them are realizing that their action has digged a pit and the industry is now at the bottom of it.

The whole situation is indefinite, but it is unquestionable that there has been a great change in the mental attitude of the industry during the last 12 months. It may presage nothing or it may forecast illimitable things.

At the moment it would be altogether too speculative to attempt to sum up the general trend of thought, but one thing stands out clearly and this is that we are to see many attempts to give the same performance by virtue of lighter weights and smaller motors. Weight is the great cry just now, and many an engineer is deep in consideration of what his chassis can do without. But it is thought that this is only a stage, and there are reasons for the belief that instead of being at the end of automobile development we are merely about to enter upon a new phase that may be more interesting and more important than any which have gone before.

U. S. Tire Passes Dividend

Quarterly Dividend of 1 1-2 Per Cent on Common Stock Passed—Stock Drops

NEW YORK CITY, July 3—Much speculation has been caused by the fact that the United States Rubber Co. passed its usual quarterly dividend of 1½ per cent on common stock this week. Since 1911 dividends have been paid on the common stock, of which there is outstanding $36,000,000. In 1911, 1 per cent dividend was paid; in 1912, 4 per cent, and since 1913, a quarterly dividend of 1½ per cent. Some difficulties were anticipated by stockholders when the stock dropped 13 points recently and at this time it was rumored that the usual dividend might not be forthcoming. Stock quotations dropped somewhat as a result.

The only reasons given by the company for passing the dividend are those contained in a statement from President Samuel P. Colt. He says that the net earnings so far this year are substantially the same as last year, but that the unexpected continuation of the war has made it necessary to maintain an unusually strong financial position, and that the war also makes it necessary to carry a larger supply of crude rubber than would be carried at normal periods.

In connection with the crude rubber situation, it is known that the United States Rubber Co. owns some rubber plantations in Sumatra, and it is rumored in rubber circles that crude has been costing the United States company more than some other companies, no allusion to which, however, is made by President Colt. It is understood that earnings were taken from the quick capital to care for these plantations.

Winton Will Stick to Sixes

CLEVELAND, O., July 3—The Winton Co. states that a new model of the 48 six will be brought out shortly before the New York show; there will be no reduction in the price, which is $3,250. The 33 hp. "New-size" six at $2,285 will be manufactured without change until next year. The Winton company expresses its intention of continuing to build sixes exclusively.

New Cole Six at $2,385

INDIANAPOLIS, IND., July 3—The Cole Motor Car Co., has brought out an improved new large six-cylinder car known as model 666. It is a seven-passenger design on a 136-in. wheelbase and includes many refinements which make for comfort and easy riding. It is fitted with deep upholstery and is handsomely finished.

It is in the body work that this car is most distinctive. It has a straight line effect with flat cowl and rounded radiator and long straight hood. The two extra seats are more than usually comfortable due to the additional foot room made by providing space under the front seats. There is a center cowl between the front and rear compartments, and in this there are two lockers for gloves, goggles, etc. A tonneau light is provided, a dash and service lamp and a Waltham clock. While the eight is still the leader of the Cole line, this six is provided for those who prefer this type of motor. The car is mounted on practically the same chassis as this year, the motor being a 4¼ by 5¼, L-head design with the cylinders in pairs. The price is $2,385 f.o.b. factory.

Chalmers Continues Three Models —Prices Lower

DETROIT, MICH., July 6—For 1916 the Chalmers Motor Co. will continue its present models, excepting that they will be greatly improved in many directions and will all sell at lower prices.

There will be three models, the 6-40, at $1,275, being the improved model 32 of this year, which sold at $1,400; the 6-48 at $1,550 which is the continuation of the light six which this season sold at $1,725 and the Master Six, reduced to $2,175, or $225 less than this year.

All of these models are continued because the Chalmers company found that they had met with an ever-increasing demand, and believes that by continuing them with even better and more refined bodies and many other minor improvements and by greatly increasing the production, thus making a reduction in price well possible, that it will best serve both the public and itself.

All Chalmers dealers were consulted as to the 1916 models to be, and 90 per cent expressed the wish that this year's models be continued with improvements wherever possible.

Stutz Adds a New Model

INDIANAPOLIS, IND., July 6—Under the name of the Bulldog Special the Stutz company has added a new model to its line. This is a four-passenger design like the Bulldog which has been described in THE AUTOMOBILE, but whereas the former model has a wheelbase of 120 in. the new model has 130. It differs from the shorter car also in that the front seats are not divided. There is a center cowl and in the back of this there is room for storage in compartments provided. Thermos bottles are furnished as regular equipment. The car is manufactured for the four-cylinder chassis, the motor being 4¾ by 5½.

Franklin Makes $200 Price Cut

Aluminum Substituted for Iron Reduces Weight 75 Pounds Below Last Year

SYRACUSE, N. Y., July 6—The new Franklin series which has just been brought out while showing a number of detail changes, does not make any departures from what has come to be accepted as standard Franklin practice. Such fundamental details as air cooling, laminated wood frames and full elliptic springs both front and rear are features which have come to be looked for year after year in Franklin practice.

The new model does show one radical change, however, which is in the substantial drop in prices. Instead of being $2,150, the new car sells for $1,950 or $200 lower. In both the body and chassis a number of small refinements will be noted. The Franklin claim of lightness has been accentuated to the extent of 75 lb. by the use of aluminum instead of steel in several of the important parts of the power plant and running gear. The fenders are now aluminum as are the air jackets around the cylinders and the valve housing. The gear shifter lever has been moved forward 4 in. in order to allow passengers entering from the left to step behind it. The tire pump mounting has been changed and instead of driving directly from the generator shaft as for the last model it is now connected by reduction gearing. This was done because the generator is geared up to such an extent that the motor had to be run very slowly in order to afford proper pump action. It can now be run at its normal speed without any danger to the pump.

The body is now made without striping or molding and its simplicity is accentuated by placing the horn under the hood. One of the comfort features is the setting of the seats more deeply and, for beauty of design, greater cleanness has been secured by removing the handle from the hood and attaining a form which corresponds more closely to the streamline. The standard color is green with russet wheels.

The Franklin motor is a 3⅝ by 4 valve-in-head design with the cylinders cast singly. It is featured by its seven-bearing crankshaft, helically-driven camshaft, single ignition with Eisemann magneto and Dyneto starting and lighting. The clutch is a disk, the gearset a three-speed selective mounted amidships and the final reduction 3.7 to 1 in the rear axle. The wheelbase is 120 inches, the tires 34 by 4½ and the wheels, wood. Throughout the entire car, lightness of design has been made a feature.

Simplex Takes Over Crane Co.

Will Build Crane-Simplex Model and Continue Others—Crane Second V. P.

NEW YORK CITY, July 7—The Simplex Automobile Co., of New Brunswick, N. J., has bought out the entire plant, assets and good will of the Crane Motor Car Co., Bayonne, N. J., according to reports given out to-day. Henry M. Crane, former president of the Crane Motor Car Co., is now second vice-president of the Simplex company, and is taking direct charge of the engineering work at the New Brunswick plant with R. B. Wasson as factory manager.

The Simplex company will continue the models made for 1915 but will build in addition a new model which is practically identical with the Crane model 4. This will be known as the Crane model Simplex and is intended for those who desire extremely careful workmanship, regardless of the price of the car. The exact price has not as yet been fixed. The car will be built with a wheelbase of 143½ in. and a body space of 112½ in. The tire equipment will be 36 by 4½ forward and 37 by 5 rear. The motor is a six with 4⅜ bore and 6¼ stroke with the cylinders cast in two blocks of three. A rigid crankshaft 2¾ in. in diameter is one of the features of the motor. The carbureter is a Newcomb-Crane and the camshaft, magneto, starting motor, lighting generator, water and tire pump are all operated through silent chains. Steering is left with center control.

The Crane Motor Car Co. has been known to motorists in the East as a concern devoted to the building of high-priced cars, largely to order, although the car was made in standard models. The model 4, chassis alone, listed at $8,000, and it was built with a view of providing the last word in automobile luxury and finish. The bodies for this chassis were generally made by the large body makers to suit the special requirements of the purchaser with the result that the finished cars were among the highest-priced products in America.

—

Hendee May Buy Pope Plant

HARTFORD, CONN., July 2—It is stated here on good authority that the Hendee Mfg. Co. of Springfield, Mass., is considering the purchase of the Westfield, Mass. plant of the Pope Mfg. Co. now operated under a receivership. If the property is not disposed of before July 20 it will be sold at public auction by the Pope receivers at the Westfield offices of the company. Every bidder will be required to deposit a certified check for $25,000 on some national bank in New York before the opening of the sale. The Pope company has been ordered by the United States district court at Boston to dispose of the property for a price not less than $725,000. This amount has been offered by H. Preston Cousens who represents a New York syndicate. Acquisition by the Hendee interests is taken to imply resumption of operations at Westfield on a larger scale than ever.

—

Jackson Will Have Two Eights and a Four for 1916

JACKSON, MICH., July 7—While full specifications have not as yet been decided upon, the Jackson Automobile Co. of this city, is bringing out two eight-cylinder models which will soon be passing through the plant in active production. The four-cylinder car will be continued.

—

Elgin to Make Van Speedometer

ELGIN, ILL., July 7—The Elgin National Watch Co., of this city, one of the large watch makers, has just closed negotiations with the Van Sicklen Co., Aurora, Ill., to manufacture the Van speedometer which has been on the market for more than a year, and which is now used on seven cars as standard equipment. The Van Sicklen Co. has been under the direction of N. H. Van Sicklen, Sr., who for years was publisher of *Motor Age*, Chicago.

—

Auburn Markets Four and Six

AUBURN, IND., July 2—Two models, a T-head four and an L-head six, are being marketed by the Auburn Automobile Co., this city, for 1916. Both motors have the cylinders cast in a single block with unit power plant arrangement of the clutch and gearset. Three-point suspension is also employed.

The six is a 3½ by 5 with a cone clutch, three-speed gearset, floating axle and a 126-in. wheelbase. The tires are the 34 by 4 Goodrich straight side and the body a full seven-passenger design with four full U doors with invisible hinges. The auxiliary seats in the tonneau fold into the backs of the front seats. A roomy three-passenger roadster is also provided. The price with either body is $1,550.

The four-cylinder 3⅞ by 5 design follows closely along the lines of the six, except that the motor is a T-head as stated. The clutch is a cone, the gearset provides three speeds and the rear axle is floating. The bodies on this car are a five-passenger touring and a roomy three-passenger roadster. The price with either of the two bodies is $985.

—

Bower Increases Stock

DETROIT, MICH., July 3—The capital stock of the Bower Roller Co. has been increased from $225,000 to $300,000.

Two-Speed Axle Decision

Court of Appeals Says Cadillac Infringed Austin Patent—Austin's Renewal Granted

CINCINNATI, OHIO, July 1—The decision granted Walter S. Austin of the Austin Automobile Co., Grand Rapids, Mich., last January, against the Cadillac Motor Car Co., Detroit, for infringement of Austin's two-speed rear axle patents by the Cadillac company in the United States district court, has been confirmed by the United States Circuit Court of Appeals, Sixth Circuit in this State, the court holding that Austin's patent No. 1,091,618 covering a two-speed rear axle construction has been infringed by the Cadillac company in the axle design used on its regular cars during the season of 1914.

It is shown in the review of the case by the court that Cadillac in its negotiations with the Austin company received a two-speed Austin axle which it later returned to the Austin factory and after which time the Cadillac company brought out its own design of two-speed axle, which was used in its cars and which design has been declared an infringement. The court after minutely describing the Austin axle and the infringing Cadillac axle declares that while some of the details of design differ yet the basic features are the same and that Cadillac infringes claim No. 10 of the Austin patent.

The Cadillac defense insisted that according to this claim the Austin device referred to an arrangement of bevels, gears and clutching devices in the axle, and that it was limited to this particular method of clutching, but the court held otherwise and decided, "We shall not read into one claim elements which expressly characterize another, by which alone the two substantially differ and which are not necessary to make it operative; and that if Austin's only real invention resided in his peculiar clutch mechanisms claim 10 would be void, because broader than the invention."

This part of the court decision refers to the fact that in the Cadillac design the two pinions on the continuation of the propeller shaft are both mounted on sleeves loose on the shaft but capable of being clutched thereto, whereas in the Austin axle while the arrangement of the pinions is the same the smaller pinion on the rear end of the shaft is solid to the shaft and the forward one capable of being clutched to the shaft. In this connection the court has held that Austin's patent is broader than one covering any particular type or scheme of clutching and that the inventive feature of his

device is in the arrangement of a double pair of bevel pinions and gears, the higher gear ratios being outside in the group and the lower gear ratios inside. In the Cadillac the two large bevels are bolted together, whereas in the Austin axle they are separate gears capable of being separately clutched to the shaft, but yet this difference of detail working out of the scheme does not conflict with the basic features of Austin's claims.

In this connection the court held that Cadillac had a legitimate right to develop any design of two-speed axle, using whatever clutching schemes may be deemed best providing it does not infringe the Austin claim of relative arrangement of the two sets of pinions and bevels coupled with clutching devices.

The court held that previous examples of multi-speed axles did not conflict with the Austin patent because the cases cited were not in the precise field filled by the Austin patent. The Minerva patent is cited, but it is shown that its scope was that of combining a gearbox with a rear axle and that the several speeds were for this purpose, whereas in the Austin patent the two-speed axle was intended to be used with a conventional gearbox as used on motor cars to-day.

Austin's Combination

The court holds that in spite of earlier efforts along perhaps closely allied lines, that Austin's efforts involve inventive genius as compared with Minerva, which is looked upon as probably an impractical construction. In this connection the court says: "It is true that each of these missing elements can be found in some one of the prior patents; but this is not enough to negative invention. If the selection of elements from existing machines into a complete combination has, for the first time, produced, from a practical and commercial aspect, a new result, invention may well be predicated thereon; and if producing more of a woven fabric within a stated time was a 'new result' within the meaning of this familiar rule (Higgins vs. Loom Co.), so must be the additional mileage per gallon of gasoline, the saving of wear and the additional ease of riding, all of which the Cadillac company so strongly attributed to the two-speed axle."

Austin's Renewal

In referring to that part of the argument between Austin and Cadillac in which Austin was expecting to get broader claims on his axle after it had been shown to the Cadillac company, and the possibility of obtaining such claims was discounted by the Cadillac company the court holds:

"There is no doubt that Austin at first regarded his relative arrangement of gears and clutches as characteristic of his invention, both according to the specifications and claims allowed on his original invention. The idea of one fixed member and one clutch member upon the shaft and one of each on the axle was inherent in all these. . . . The defendant's device does not infringe these claims. . . . Austin took further counsel, abandoned his application and filed another in renewal and on this new application he secured claim 10. . . . Very likely the necessity for these new claims was brought to Austin's mind by his dealings with Cadillac; and by observing the Cadillac design. . . . Austin's original failure to claim a certain gear arrangement in connection with his clutching scheme, ought not on any principle prevent him from claiming it as soon as the propriety of doing so occurred to him. . . . The fact that this feature (high-gear ratio set of pinion and bevel out of the low-gear ratio set of pinion and bevel) was regarded by Austin as his chief advance and that he so presented it to Cadillac, and that Austin notified Cadillac that he expected to get better claims in this respect."

The amount of damages which Austin will collect, in the event a rehearing is not granted cannot be determined until the usual routine of accounting has been carried out.

Empire Six Price $1095

Motor Develops 46 Hp. at 2200 R.P.M.—Unit Power Plant and Floating Rear Axle

INDIANAPOLIS, IND., July 3.—Closely following the announcement that the Empire Automobile Co. would move its factory from Connersville to Indianapolis, comes the announcement of the latest addition to the Empire line. This is a six to sell at $1095 and marks the entrance into this field of a concern which has heretofore confined its efforts to fours.

The chassis includes a unit powerplant with cone clutch, three-speed gearbox and floating axle. The wheelbase is 120 in.

The 3 by 5-in. block model motor is said to develop 46 hp. at 2200 r.p.m.. The crankshaft is carried on three bearings lined with babbitt in bronze shells. The camshaft runs in oil. The main lubricating system consists of a constant-level splash outfit in which the oil is circulated by a plunger pump. The water pump is a centrifugal design and cooling is assisted by a pressed steel fan mounted on ball bearings.

The Stewart vacuum system is used for feeding gasoline to a Schebler carbureter. Ignition is by a battery system, employing the Connecticut automatic distributor. The electric starting and lighting is provided by an Auto-Lite outfit, working through a Bendix drive and employing a Willard 12-volt battery.

The cone clutch is housed in a bell extension of the crankcase to which the three-speed gearbox is attached. The gearset shafts are carried on New Departure ball bearings and the drive is taken from the gearset to Hartford universal joint and propeller shaft to the floating axle. Alloy steel gears and shafts are employed in this axle and the housing is pressed steel with a removable inspection cap at the rear.

The brake drums are carried on the rear wheels, which are artillery type and fitted for 34 by 4-in. tires. The brakes are equalized and are provided with simple adjustments. The wheels are fitted with either Firestone or Goodyear tires of standard equipment, nonskid being provided on the rear and an extra demountable rim being part of the standard equipment. The holder for the extra rim with its inflated tire is built integrally with the chassis upon an extension at the rear of the frame, and but one felloe band is required to carry two tires. No straps are employed.

The body incorporates a long cowl and convex sides. The front seats are divided and the doors are large. The engine hood merges into the body line without a break, tapering back from the high racing-type radiator. The upholstery is genuine leather and equipment including a Fabricoid top is complete.

Production on this car will be carried on in the Indianapolis plant of the Empire company. In this building there are 150,000 sq. ft. of floor space available for manufacturing. It is estimated that 250 skilled workmen will be employed at the time the plant is opened on July 6.

Morse Announces 1916 Car

PITTSBURGH, PA., July 3—Under the name of the Morse light car the Morse Cyclecar Co., of this city has announced its 1916 product. This is a two-cylinder V-type design with a two-speed gearbox and a tandem seating arrangement adapted for two people. The wheelbase is 105 in. and the tread 36 in. The tires are studded 28 by 3 in. and the wheels wire. The car is driven through the front axle by means of a chain from the change-speed mechanism just back of the motor which is mounted in the customary position under a hood. The price with standard equipment is $350.

Kalamazoo Co. Changes Name

KALAMAZOO, MICH., July 2—The name of the Kalamazoo Motor Vehicle Co. has been changed to that of Columbia Motor Truck & Trailer Co.

Ford Co. to Make Its Own Tires

1917 Cars Will Be Equipped with First of Annual Product of 2,000,000 Casings

DETROIT, MICH., July 6—The Ford Motor Co., according to an announcement by Henry Ford, will begin manufacturing its own tires which should be ready for the 1917 cars. The new tire plant will be a part of the new manufacturing center to be built for the Ford tractor. The output of tires is placed at 2,000,000 for the first year, and the $5 per day schedule will apply to all workers at the new plant, it being estimated that by 1917, 50,000 to 60,000 men will be employed by the Ford company.

Jones Six Continued for 1916

WICHITA, KAN., July 5—The Jones Motor Car Co., this city, has brought out its 1916 product which is in the form of a six-cylinder assembled car containing such well-known units as the Rutenber motor, Stromberg carbureter, Warner steering gear, Detroit gearset, Warner vacuum feed, etc. Starting and lighting equipment is furnished by Gray & Davis, Inc.

The price of the car has not as yet been stated but some of the specifications of importance include an L-head block 3 by 5 motor of six cylinders and three bearing crankshaft. The wheelbase is 118 in.

Fostoria Light Car Co. Formed

FOSTORIA, OHIO, July 2—The Fostoria Light Car Co., has been incorporated with $100,000 capital stock. The company will bring out a light car at a popular price. The incorporators of the company are: R. J. Ridgway, J. H. Jones, Ira Cadwallader, Charles Ash, of Fostoria, and A. C. George of Lima.

Packard, Advance-Toledo Pump Equipped

NEW YORK CITY, July 3—The Packard Motor Car Co. will equip its cars with the Advance-Toledo motor driven tire pump. The Monarch Motor Car Co. recently added this pump to its equipment on its eight.

Every Sixth Family in Kansas an Automobile Owner

TOPEKA, KAN., July 3—There is an automobile for every sixth family in Kansas, according to J. T. Botkin, Secretary of State. When the license books were closed there were 59,477 automobile licenses in the State. This is one for every 28.3 persons. The ordinary average is five persons to a family so that every sixth family in the entire State has an automobile under population figures. The estimated cost of the cars is around $60,000,000.

Kansas spent over $20,000,000 for cars last year. There were 39,889 cars licensed in June, 1914. The increase has been almost 20,000 cars in the twelve months.

100-M.P.H. Record for 5 Miles

OMAHA, NEB., July 7—*Special Telegram*—Orr, in his Maxwell, made 5 miles in 3 min., or 100 m.p.h., in the 300-mile race held on the new 1¼-mile board speedway here Monday, thus establishing a new mark for that distance, the best previous record having been made by Bragg in a Fiat on the Los Angeles board track, in 3:11.75, May 5, 1912.

Buick's Record Payroll

FLINT, MICH., July 3—For the last two weeks the pay-roll of the Buick Motor Co. was in excess of $223,000, which established a new record for this time of the season.

Studebaker Insures Employees

DETROIT, MICH., July 6—An arrangement was completed a few days ago between the Studebaker Corp. and the Equitable Life Insurance Society of the United States, New York, whereby 6500 of the 13,000 workmen now employed by the corporation are insured for life while the remainder will also be insured in the same way within a short time. No matter how long the Studebaker workman has been with the concern, through the deal with the insurance company he will have the benefit of a life insurance.

Packard Gets Prize at Fair

SAN FRANCISCO, CAL., July 2—The Grand Prize of the Panama-Pacific Exposition for excellence in the field of automobile manufacture has been awarded the Packard Motor Car Co., of Detroit. Fifteen gold medals were distributed in the transportation division and among those who received prizes were Pierce, Cadillac, Ford and Rolls-Royce.

McClurg Rubber Elects Officers

COSHOCTON, OHIO, July 3—The McClurg Rubber Co., recently organized to manufacture tires, has elected the following directors: J. S. McClurg, C. M. Christenson, H. T. Forrest, J. L. McClurg and W. Z. Davis. The directors then elected the following officers: President and general manager, J. S. McClurg; vice-president, C. M. Christenson; and secretary and treasurer, H. T. Forrest. The company expects to be operating by July 1.

Overland Builds in St. Paul

Contract for $250,000 Building Closed for Combined Service Station and Warehouse

ST. PAUL, MINN., July 6—A contract for several acres of land has been closed in this city for the erection of a $250,000 warehouse by the Willys-Overland Co. The plant will combine the facilities of a warehouse and an assembling station, according to present indications. St. Paul is considered as an excellent distributing point for the northwestern territory as the shipping facilities by rail and water are unsurpassed.

Overland Plant in Minneapolis?

MINNEAPOLIS, MINN., July 3—The Willys-Overland Co. has been negotiating for the purchase of a 18-acre site in this city for the purpose, it is said, of establishing a plant in the future.

Allen Dealers Convene

FOSTORIA, OHIO, July 1—Tuesday and Wednesday of last week the distributors of the Allen Motor Co., makers of the Allen cars, held a convention and general get-together party. The 1916 Allen car was exhibited to the dealers who attended a general meeting Tuesday afternoon, when the new car was lectured upon by the factory officers and engineers. Tuesday night the guests of the factory were banqueted and Wednesday the party was taken to Bucyrus, where the factory making the motors and gearsets for the cars was visited.

Hans Co. Now National Gauge & Equipment Co.

LA CROSSE, WIS., July 3—The Hans Motor Equipment Co., Las Crosse, has been reincorporated with a capital of $200,000 under the name of the National Gauge & Equipment Co., by D. G. MacMillan, P. M. Gelatt and J. M. La Vaque. The new company is issuing a new advance bulletin which gives a brief description of the complete line of pressure gauges which it manufactures.

2-Mile Board Track for Kansas City

CHICAGO, ILL., July 3—Twenty residents of Kansas City, Mo., who are engaged in the promotion of a company to build a speedway in their city, were in Chicago recently to witness the 500-mile race and study the construction of the local board track. The expedition was under the auspices of the mid-continent expedition association which plans to build a 2-mile automobile track of

wood at the official stopping place of the transcontinental balloon races and at a strategic point on the national old trails highway.

—

Erskine Slated for Studebaker Head

NEW YORK CITY, July 7—A. R. Erskine is slated for the Studebaker Corp. presidency, the election to take place tomorrow at a meeting of the directors in this city. The stockholders met to-day in Jersey City and elected the directors to act on a provision for the classification of the directors into five classes of equal number and for the election of one of said classes in each year hereafter.

—

Hayes Wheel Enlarges

ALBION, MICH., July 3—The Hayes Wheel Co. of this city, which makes the hubs for the wheels made by the parent plant, the Hayes Wheel Co., in Jackson, will erect a new plant to be ready for occupancy September 1. When completed the company will employ 200 men here, or double its present working force, and the production will be more than doubled. Machinery valued at $15,000 has already been purchased and by the time the new building is ready it is expected that from $50,000 to $60,000 will have been spent.

—

English Motor Works Burned

LONDON, ENGLAND, June 29—Fire recently did $500,000 damage to the motor works of Brian Hughes & Strachan at Park Royal. The buildings covered 3 acres and contained 100 Red Cross motor ambulances and 200 army motor vans. The vehicles, which were ready for delivery to the government, were destroyed.

—

McNaull Tire Opens Branch

ST. LOUIS, MO., July 3—The McNaull Auto Tire Co., Toledo, O., has opened a branch here at 5032 Delmar boulevard. The local office has been organized as the McNaull Tire Co. of St. Louis.

—

Automobiles for Topeka R. F. D.

TOPEKA, KAN., July 3—Motor service has been installed on two rural routes out of Topeka. Two men who owned automobiles were appointed to be the first mail carriers using motor cars in Topeka.

—

Apco Accessory Prices Reduced

PROVIDENCE, R. I., July 3—The Auto Parts Co., Providence, R. I., manufacturer of the Apco line of specialties for the Ford car, announces a reduction in the list price of its muffler cut-out and valve stem adjusters. The last named now retail for 20 cents the set and the muffler cut-out at 45 cents each.

New Kissel 1,000 lb. Truck

—

Is Shaft Driven—Capacities of Line Readjusted—1 1-2 Tonner Reduced $100

HARTFORD, WIS., July 1—Shaft drive has been extended in the product of the Kissel Motor Car Co., Hartford, Wis., to embrace one more capacity in its line of ½, 1½, 2, 3, 4, and 6-ton vehicles, just announced. The capacities of the Kissel model have been somewhat readjusted, the 1000-lb. vehicle being a new model which has been promised for some months. The 1-ton model rated at ¾ for 1 ton is the 1500-pounder announced for 1915. The 1½-ton model is the 1 tonner of 1915 rated for 1916 at 1 to 1½ tons. The 2-tonner, rated at 1½ to 2 tons, takes the place of the discontinued chain-driven 1½-ton. The 1915 2½-tonner is continued with chain drive with a rating of 2½ to 3 tons. The 3½-tonner has 3½ to 4 tons and the 6-tonner without change.

Structurally the new 1000-pounder does not differ from the other shaft-driven models except that the final drive is through bevel gears instead of worm gears. It is designed for pneumatic tires as are the 1 and 1½-ton models and lists at $950 for the chassis. The ¾ to 1-tonner lists at $1,500; the 1 to 1½-tonner has been reduced from $1,850 to $1,750; the new worm-driven 1½ to 2-tonner is priced at $2,100, the same as the 1½-ton chain-driven model. No other changes in price have been made. The 2½ to 3-tonner listing at $2,750, the 3½ to 4 at $3,350 and the 6-ton model at $4,350. All Kissel trucks have pressed steel frames and motors located under conventional hoods. All shaft-driven models have unit power plants, those with chain drive having the gearset incorporated with the jackshaft. Left steer and center control are employed on all models. The characteristic cellular radiator is used throughout the line. Only the chain-driven models are fitted with a differential lock. Timken and Timken-David Brown axle equipment is a consistent feature of the line.

—

McKinney with Champion Plug

NEW YORK CITY, July 3—E. C. McKinney, formerly with Splitdorf, has joined the sales force of the Champion Spark Plug Co., Toledo, and will represent it in Texas, Louisiana, Arkansas and New Mexico.

—

Mich. Buggy Refuses $50,000 Offer

KALAMAZOO, MICH., July 3—An offer for $50,000 for the plant of the former Michigan Buggy Co.'s plant and property has been turned down by the Michigan Mfg. Realty Co. which wants $60,000. The offer was made by Attorney C. A. Burras, of Chicago, acting for those interested in a new automobile manufacturing concern now being organized. It was stated that the men behind the new enterprise have plenty of capital and that the company will be finally organized and incorporated in the state in which the plant will be located. The matter of a plant has now been taken up with the Cleveland Chamber of Commerce.

—

Sheldon Men to Convene

WILKES-BARRE, PA., July 6—Beginning July 14 and continuing for several days, the salesmen of the Sheldon Axle & Spring Co. will be in convention at the plant in this city. Men from both the spring and axle departments will attend. In addition to important redistricting of certain territories, addresses on selling and merchandising and the effect of advertising on the marketing of an output will be made by men who are in close touch with the rapid advance of the Sheldon company in the parts field.

—

Motorette Debts Not All Paid

HARTFORD, CONN., July 2—L. A Howard as receiver for the C. W. Kelsey Mfg. Co. of Hartford, which made three wheeled vehicles called Motorettes want money with which to pay the bills of th concern and accordingly appeared befor Judge Thomas in the United States cou with a motion for authority to assess th stockholders for funds to pay the co cern's obligations which amount to mo than $20,000 above the assets. A hearin will be given on the motion in t autumn.

—

Walpole Petition Denied

BOSTON, MASS., July 3—Judge Dod in the United States District Court y terday denied the petition of Maurice Sollers, a stockholder in the Walp Tire & Rubber Co. asking leave to int vene in the case in order that he mig appeal from the court's decree orderi the sale of the company's assets and c firming the sale. The petitioner sta that he desired to appeal in behalf himself and a group of stockholders.

Dixie Light Car Makes Début

VINCENNES, IND., July 1—The ini product of the Dixie Fiscal Co., V cennes, Ind., has put in an appeara It is a light car styled the Dixie and be made in three models, roadster, t ing and speedster. The two former have standard tread though the sp ster will have 36-in. tread. A fea of the car is the use of coil springs.

Service Heads Want Standard Policy

2-Day Detroit Convention of Service Managers Votes to Draft Standard Service Policy—Different Systems for Trucks and Passenger Cars—Salesmen Injure Service—Better Control of Spare Parts to Dealers

DETROIT, MICH., June 30—Further impetus to the movement for a standard service policy was given by the Service Managers' Convention which was in session at the Hotel Statler here today and yesterday. Service men and other officials of motor car and truck plants from all parts of the country were in attendance. Alfred Reeves, general manager of the National Automobile Chamber of Commerce, who presided, said that a wonderful amount of good must undoubtedly come from the gathering, and that it was one of the best of its kind he has ever attended.

To Get Service Policy

A committee was voted to formulate into a standard policy the ideas of the convention as to what should constitute the service the dealer should render the purchaser of a car. It was also voted to recommend to the N. A. C. C. that it start an advertising campaign to aid in telling the owner what he should expect in the way of free service, and also to get to the various local trade organizations along this line.

It was the majority attitude that general repair shops should not be given discounts on parts, this being against the ethics for dealer protection.

Different service policies for passenger cars and trucks were deemed necessary due to the diverging conditions entering into the work of the two classes of vehicles. The need for censoring dealers' parts orders was brought out, this applying especially to the small dealer, whose experience would not make him so good a judge of what parts he should carry as the manufacturer is.

Much discussion of the C.O.D. method of payment for parts ordered was discussed, and most agreed that though it has its drawbacks, it is the best policy to pursue, taken from all angles.

Standard Policy Backbone

That there is need for some form of standard policy on the matter of service which the car owner gets free from the dealer, there was little doubt. As Mr. Reeves put it, a standard policy would be a printed backbone in the hands of the dealer. It would cut out the cut-throat competition on service which is now doing much to ruin dealers' business. In fact, the matter of a service policy was the real cause of the convention, for it was desired to get some expression on the subject from the service men.

Service Pointers

A standard service policy would be a printed backbone in the hands of the dealer. Alfred Reeves, General Manager N. A. C. C.

Four essentials in dealers' service are: Parts, repairs, supervised instruction regarding the car, and cooperation with the owner. Charles Gould, Maxwell.

The hint of buying a new car is often the bait which makes the dealer do more than he should for a car owner. E. W. Cotton, McFarlan.

Installing a vehicle properly after the sale is a legitimate part of the service. J. V. Coy, Peerless.

Road repairmen disrupt organizations, cost money, and make it too easy for customers to get service to which they are not entitled. E. T. Klee, Stutz.

Service does not mean giving something for nothing. A. B. Hanson, Chalmers.

Service is providing all the necessary means for keeping a car running. A. B. Cumner, Autocar.

Dealers' service is often a cut-throat business done to sell cars. H. H. Carpenter, Saxon.

Macauley Favors It

Alvan Macauley, vice-president and general manager of the Packard company, thinks that service and a standard policy are the vital things of the business now. Whether or not the manufacturers get this service matter down to a reasonable basis and hold it there, will largely govern their staying in the business, he said. Dealers have to contend with all sorts of customers, such as women, men trading on their name, etc., and most of these are good bargainers who will get all they can for nothing. As this gratis treatment often eats up the dealer profit, all must get together and have an understanding of what constitutes the service to which the customer is entitled.

A. B. Cumner, service manager Autocar company, believes the time is ripe for such educational campaigns as will acquaint the public as to what service should and would consist of. Mr. Reeves explained that the prime reason for a standard policy is that nearly every dealer handles several makes of cars, and if there is not some standardization in the service he is to render all buyers, he is apt to hold the manufacturer with the best policy up as an example to the others.

E. W. Cotton, secretary McFarlin company, used the words "coerced service" to describe the kind of service which the dealer often is obliged to give under the present conditions. The hint of buying a new car often is the bait which makes a dealer do more than he should for a car owner.

Four Essentials

In establishing what he thinks constitutes service to the owner, Charles Gould, manager of service for the Maxwell company, laid down four main points to which the dealer should pay special attention:

1. Parts; 2. Repairs; 3. Supervised instruction regarding the car; 4. Cooperation with the owner.

In connection with the first of these, a sufficient supply of parts located so as to get them to the customer quickly is very important. Accidents, the lack of oil and grease in the machine, driving and temperamental differences between owner and dealer are not points which should come under the definition of free service. The owner ought to know exactly what gratis service he will get, and before any repairing is done, he ought to be told how much it will cost, if it is possible to tell him. The manufacturer should really be the umpire between the dealer and the owner in the matter of disputes, Mr. Gould believes.

J. B. Coy, technical and service department, Peerless company, said that there should be little variation in the opinions of the delegates on this service matter. Installing a vehicle properly after sale was emphasized by him as a part of service, and further than that the manufacturer should stand on whatever he feels morally obligated to deliver.

The Spoiled Customer

W. H. Doddridge, service manager, the Winton company, pointed out that the

customer has been spoiled in most cases until he expects everything he can get now. Any standardization will have to be flexible, he thinks, so long as owners have different ideas. Much of the imposing on dealers is due to the overworking of such words as booster and big man. These are used by persons trying to get something for nothing from the dealer. Salesmen are also responsible for a lot of service evil, for when selling cars, they imply a great many things that the dealer is unable to do free. They use another overworked phrase, "Leave it to me."

E. T. Klee, service manager, Stutz company, is against the practice of having road repair men, as they disrupt organizations, cost money and make it too easy for the customer to get a lot of service free which he is not entitled to. The dealer should not have a territory so large that he cannot send a repair man at small expense from his own shop.

Salesmen Bad Offenders

Much of the service trouble begins in the sales department in the opinion of A. J. Banta, Chicago branch, Locomobile company, who says that more is given away by the service department in making good the extravagant promises of the sales department than in any other way. Service means everything for nothing with the salesmen.

That the salesman should keep service as far in the background as possible is the view of G. E. Drawe, assistant secretary and treasurer, Pathfinder company, who emphasized the fact that the car buyer is usually a better salesman than the car salesman, else he would not have the money to buy a car. Thus, he sells the car salesman for whatever he wants in the way of free service.

A. B. Hanson, Chalmers service manager, quoted the printed text of his company's idea of service. It is that service does not mean giving something for nothing. It means giving prompt attention at the least possible cost.

Service Defined

Mr. Cumner offered two good definitions. Service, he said, is the providing of all necessary means of keeping a car running, while free service is the taking care of mistakes and conducting an educational campaign.

Educational Service

H. W. Drew, service department Marmon company, pointed out that service is doing as much as possible for the owner at the least possible expense. He thinks a lesson might be drawn from the service rendered by certain of the parts makers, such as storage battery people, electrical equipment makers, etc. Service should be more educational and less individual, Mr. Drew aptly put it. If better information were put into instruction books, and if letters were sent to owners from time to time on the care of various parts of the car, much could be accomplished.

Dealers' Service

The question of whether or not the dealer's service policy should go farther than the manufacturer's warranty was generally answered in the affirmative, it being considered that this warranty refers specially to defective material and workmanship. Then, the dealer's policy refers to a special field and it varies.

It is a ticklish question and one that is hard for the manufacturer to dictate, Mr. Drew said. The successful dealer has devised special methods which apply to his community, and he is naturally more familiar with his clientele than is the manufacturer, and he naturally should radiate on the manufacturer's guarantee. The small and weak dealers are the ones who need an educational campaign the most.

H. H. Carpenter, service manager, Saxon company, thinks the service given by dealers is a cut-throat proposition which is done to sell cars, promising anything to make the deal. He agrees with an educational campaign to make a common ground for all to work upon.

Wants Definite Service

On the other hand, Percy Owen, Chalmers general sales manager, believes in definitely stating what the dealer should do in the way of service. He outlined the policy which his concern is operating upon, explaining the distinction which is made between what is termed t chnical service and shop service or full repair work. The technical service, which takes in thorough inspection and adjustment of the car, is what the dealer is instructed to render free for a stated period. The dealer also absorbs the labor cost on replacement parts which the manufacturer sends free, this within reasonable limits, of course.

Truck salesmen are superior to passenger car salesmen in the opinion of L. L. Virgil, service manager, the Jeffery company, who says that he has no special trouble through salesmen promising more than the factory can do. Before anything can be done on the matter of starting an educational campaign on service, the committee will have to decide on what policy is to be followed, and then this will have to be approved by the head officials of the various companies through the N. A. C. C., Mr. Reeves explained.

Trucks and Cars

Up to a certain point, service policies for passenger cars and trucks can be the same, but the work they have to do and the attitude of the owners are so different that it seems advisable to lay down separate policies for the service treatment of the two classes of cars. This was the gist of the paper which Mr. Macauley read on the subject.

For either class the warranty work is the same. This means the repair work which the manufacturer does gratis for moral reasons. Good-will advertising, conditions of service and requirements dictate separate policies beyond this point. Truck drivers do not have time during business hours to stop and make repairs, while passenger car drivers and chauffeurs have time. Trucks are relatively slow-moving vehicles, and it therefore takes a comparatively longer time to bring them to a service station than it would a passenger car. Further, they are less under the owner's supervision than a passenger car, and they also operate on solid tires. All of these things make the service problem different. The particular policy for service which is laid down is not important. It is the placing of something definite in the salesman's hands that is important, Mr. Macauley said. Let the owner know exactly what to expect.

Representatives of White, Reo, and others who make both cars and trucks said that their policies for the two classes of vehicles differ, generally more leniency being exercised with the trucks.

Censoring Parts Orders

The problems of how the manufacturers can assist in preventing dealers from overstocking and being obliged to return obsolete parts was well handled by C. W. Matheson, director of service for Dodge Brothers, who said that parts orders should be carefully looked into to prevent unnecessary investment and loss to manufacturers through having to redeem obsolete parts later. When a maker contemplates a change, dealers should be advised so as not to put in orders for parts soon to be superseded. He advocates a card ledger system, crediting and debiting it as parts are added or taken out. This is for the dealer By taking into account the average selling rate of cars in any territory, it is easy to arrive at the average consumption rate of parts, and this procedure should be carried out in connection with orders. Mr. Matheson believes in giving a dealer a time limit of 1 year, after which is becomes optional with the manufacturer to redeem obsolete parts.

R. E. Winans, service manager Paige company, suggested taking the experience of other dealers in suggesting to new dealers how many parts to carry in proportion to the number of cars.

Obsolete Parts

Summing up the discussion on the topic, is was agreed that the main obje

is to supply the consumer, so that nothing should be done that would curtail the quick service on repair parts. There was some sentiment for penalizing the dealer for the lateness of return of superseded parts. That is, discounting them after a certain time. It was also recognized that geographical conditions might make one part more important in one locality than another. It was considered a good thing to use a maximum and minimum scheme, whereby the dealer is required to order more of each part when the number on hand falls to a set minimum. In this case, he requisitions for sufficient to bring the stock of that part up to the pre-determined maximum. He has no choice in the matter. It did not seem necessary for a dealer to carry parts for cars older than two years, such parts coming from the stock at the factory.

Standardized Account

It was brought out by A. H. Ransen, manager parts order department, Studebaker, that inasmuch as the parts order department is a business within itself, there should be a standardized plan for handling the parts accounts with dealers. Among the features should be a deposit to guarantee parts accounts, and a cash discount for prompt settlement. It is primarily a matter of dealer education, also.

Mr. Owen is strongly in favor of a deposit per car order on parts, and believes that a standard form of accounting would assist dealers. He thinks the C.O.D. system a fixture. The keynote was struck by W. D. Smith, Cole service manager, who said that it is particularly essential, since dealers handle different lines of cars.

General Repair Shops

J. A. Harris, Jr., advertising manager, the White company, took the stand in dealing with the subject, Should Manufacturers Encourage General Repair Shops by Selling Them Parts, that the matter of repairing and overhauling will soon become so great in certain localities that the dealer will not be able to handle it all, and therefore outside shops will have to be established. Then care should be taken in shop selection to make sure that they can do the work properly and as quickly as the parent shop.

C. J. Boilon, service manager, Kelly-Springfield truck company, thinks it inadvisable to have repair shops where there is a dealer, as this creates friction. J. F. Plummer, Locomobile company, also believes that dealers should be protected, and therefore is not in favor of discounts to local repair shops in territories covered by dealers. Where there are no dealers, then establishments on a parts selling basis are advisable for the convenience of owners. Several others were practically of this same opinion.

Owner Protection on Replacement

There was little discussion of the paper, How Can the Manufacturer Satisfy Himself That the Dealer Who Receives a Credit Installs the Part in the Customer's Car Without Charge, which was read by Mr. Klee. He outlined a method of having the owner sign a tag which is attached to the part sent back to the factory for replacement. On credit being issued to the dealer, the owner who signed the tag is notified. Several modifications of this method were explained, but they were all along the same line of advising the car owner.

Service Coupons

The matter of issuing service coupon books to customers was brought up, and there was some discussion. Several individual dealers' schemes independent of factories were explained, in addition to a description of the Federal, Chalmers and other factory coupon book plans. It is evident that the scheme admits of many ramifications.

—

Muncie Plants Running to Capacity

MUNCIE, IND., July 1—The automobile concerns here are crowded to capacity and some of the companies are turning down orders because of rush business.

The Warner Gear Co. has 1000 men at work in its plant proper and has smaller forces at work in two other factory buildings. The Muncie Gear Co., has all the business it can handle and is employing a large force. All other gear and parts concerns as well as the Inter-State automobile factory are running practically at capacity. All are hunting for additional workmen.

—

Federal Tire Repairs Free

MILWAUKEE, WIS., July 3—The Federal Rubber Mfg. Co. of Milwaukee, with works at Cudahy, Milwaukee county, has established a factory branch and service station in the city of Milwaukee, occupying a store and warehouse at 509 Broadway. The announcement signed by H. A. Githens, vice-president, is somewhat unusual with regard to the extent of the service the station will give. It says: "The object of this service station is to provide free service to users of Federal tires. By free service we mean free; that is, removing and applying Federal tires without charge; repairing punctures in Federal tires and tubes without charge, and repairing cuts on Federal tires without charge. This station will be open from 7 a. m. to 11 p. m. daily and Sunday, and free air will be furnished during these hours." The new Federal service does not change the list of jobbers and retailers of Federal goods in Milwaukee.

Briggs Assets Are $751,999.33

—

Scheduled List Places Liabilities at $556,424.83—Creditors to Meet July 15

DETROIT, MICH., July 1—The Briggs-Detroiter Co. which was declared bankrupt June 28, to-day filed its schedule of liabilities and assets. The former totaled $556,424.83 and the latter $751,999.33.

The liabilities include $4,452.33 due to shop and office workers; $158,048.56 due to three creditors holding securities and consisting of the Dime Savings Bank, Detroit, $109,857.80, the People's National Bank, Jackson, Mich., $31,140.76 and the Gray estate, Detroit, $17,050.

Listed Liabilities

The unsecured claims total $391,925.37. Among the several hundred creditors coming under this section, the following are the biggest: Capitol Body Co., Indianapolis, Ind. $29,429.34; Griswold Motor & Body Co., Detroit, $20,714.52; Brown-Lipe-Chapin Co., Syracuse, N. Y., $14,838.52; Bearing Co. of America, New York, $4,367.74; A. B. C. Castings Co. Cleveland, Ohio, $4,929.92; B. F. Goodrich Rubber Co., Detroit, $15,996.74; Kelsey Wheel Co., Detroit, $23,316.23; Long Mfg. Co., Detroit, $6,853.44; New Departure Mfg. Co., Bristol, Conn., $11,487.64; Muncie Foundry & Machine Co., Muncie, Ind., $4,468.05; Penn Spring Works, Baldwinsville, Pa., $6,417.25; Ackerman & McNamara, Detroit, car painting and trimming, $30,010.42; Remy Electric Co., Anderson, Ind., $12,843.37; Massnick-Phipps Mfg. Co., Detroit, $28,585.31; Sheldon Axle Co., Wilkes-Barre, Pa., $9,252.67; J. C. Wilson Co., Detroit, $11,929.17; Willard Storage Battery Co., Cleveland, Ohio, $5,258.27; Royal Equipment Co., Detroit, $7,525.37; Victor Lamp Co., Cincinnati, Ohio, $4,418.27.

There also appears an item of $109,857.80 under the heading of Liabilities on notes or bills discounted which ought to be paid by the drawers, makers, acceptors or endorsers.

Assets Scheduled

Among the items mentioned in the assets schedule are the following: Real estate, $89,111.36; cash, $111.86; bills, notes, securities, etc., $114,991.10; stock in trade, $227,696.36; machinery, tools, etc., $86,062.65; debts due to petitioner, $84,826.60; patents, copyrights, etc., $150,000.

The first meeting of the creditors has been called for July 15.

The Detroit Trust Co., receiver, will not have its report on the assets and liabilities of the Briggs-Detroiter Co. ready for several days.

$1,328,000 More in Rubber

Nine Rubber Concerns Increase Capitals This Much—Goodrich Is Leader

AKRON, OHIO, July 3.—The nine big rubber factories of Summit county, Ohio, will swell the personal property valuation to the extent of $27,338,000 this year. Returns from the various rubber companies just received by the district tax assessors, show increases in personal property holdings of $1,528,000 over last year, and one decrease of $200,000, or a net increase of $1,328,000.

Real estate valuations for the rubber concerns will be the same as the 1914 original valuation, on which the rubber men agreed early last year, but which failed to go on the tax duplicate owing to the reversion to the 1913 duplicate. The realty for the Goodrich alone totals $5,000,000.

Effect of Rubber Embargo

All the rubber factories increased their personal business during the year except Goodyear, which showed a falling off of $200,000 in stock and raw material. The appraisal is based on monthly averages for the past year, and the decrease at the Goodyear is blamed on the rubber embargo placed by England, seriously interfering with the factory's accumulation of raw rubber.

The greatest increases over last year are shown by the reports of Goodrich, with $1,000,000 more than 1914; Kelly-Springfield, with a growth of $166,000, and Firestone, with $100,000.

Remarkable growth in the business of the two rubber concerns at Cuyahoga Falls is shown, the Marathon increasing its stock by $69,000 and the Falls Rubber having an increase of $66,000.

The personal returns of the various rubber companies and their increases over 1914 are given herewith:

Goodrich—$16,000,000, increase $1,000,000; total return with realty, $21,000,000, with $18,000,000 in Akron and $3,000,000 in Kenmore.

Goodyear — $4,944,000; decrease of $200,000.

Firestone — $4,130,000; increase, $100,000.

Kelly-Springfield—$848,000; increase $166,000.

Miller—$685,000; increase $40,000.

Swinehart—$310,000; increase $71,000.

Portage, Barberton — $177,000; increase $16,000.

Marathon—$184,000; increase $69,000.

Falls Rubber — $134,000; increase $66,000.

—

Market Prices Steady

NEW YORK CITY, July 5—Market prices this week were steadier, there being few changes. Tin featured the metal markets with a $2.72 drop on a 100-pound basis. This was due to the heavy importations and the increase in tin afloat to this country.

Aside from this change there was no other of any importance. There was little activity in the other metal prices. The demand for copper during the past week was of small proportions. The demand for aluminum is limited, with prices being quoted at 30 cents a pound. Fine Up-River Para rubber remained strong at 63 cents. The oils and lubricants markets were unchanged and steady.

—

Trucks Gain 4346 in New York State Over 1914

NEW YORK CITY, July 7—Between Feb. 1 and June 15, 18,981 commercial motor vehicles were registered in New York State, 4346 more than for the same period in the year 1914. Of the total of 18,981 motor trucks registered this year, 11,784, or 61 per cent, were registered at the branch automobile registration bureau in this city. This latter figure is 2246 machines in advance of the registration of motor trucks during the corresponding period in 1914, so far as this city and its neighborhood are concerned.

The statistics are contained in a report recently issued by the automobile bureau of the Secretary of State's office. Similar statistics for the same period in the year 1914 were 14,635 motor trucks registered for the entire State and 9538 for this city and vicinity, showing substantial progress is being made in the use of motor-driven commercial vehicles.

—

Chandler Dividend of 77½ Per Cent on Common

CLEVELAND, OHIO, July 1—The directors of the Chandler Motor Co. have declared a cash dividend of 77½ per cent on the $225,000 common stock, in addition to the regular quarterly dividend of 1¾ per cent on the $200,000 preferred.

The 77½ per cent on the common makes a total of 100 per cent on that issue since dividends were commenced just one year ago.

—

Prest-O-Lite Buying Up Bonds

NEW YORK CITY, July 2—The Prest-O-Lite Co. is calling for payment at 110 August 1 on the remainder of its ten-year 7 per cent debenture bonds outstanding.

There were originally issued of the debentures $2,000,000. Up to the close of last January the company had redeemed and canceled or held in the treasury for sinking fund purposes, $1,382,500 of the bonds, so that there were outstanding at that time $617,500. The indenture securing the bonds is dated June 23, 1913, and the company within two years is ready to retire the entire $2,000,000 issue which is not due until 1923.

The annual report for the year ended Jan. 31, 1915, showed net earnings of $1,338,696 after interest charges, and during the year it bought $1,039,000 of bonds for the sinking fund. In the last fiscal year the company's gross sales were $4,699,377, or $209,516 more than the preceding year, and its net earnings were equivalent to about $17 a share on the stock. For the 3 previous years net earnings averaged $1,000,000 yearly.

—

Locomobile Gets War Order

NEW YORK CITY, July 1—The Locomobile Co. of America, Bridgeport, Conn., which is building a large addition to its plant, recently took an order for 500 trucks and several hundred officers' pleasure cars, for Russia and Great Britain. The company also has a large order for France.

At the plant there are three British, three French and the same number of Russian officers inspecting every car that is turned out for their countries.

The company is working on an order

Republic Tire Receives $500,000 Foreign Order

YOUNGSTOWN, OHIO, July 1—The Republic Rubber Co., this city, has been advised by cable of an order for $500,000 worth of solid rubber tires from abroad. The name of the purchaser is withheld, but it is supposed to be the British Government. This company is now completing a contract for $250,000 worth of similar tires, and will ship the last of this lot this week. The order calls for the delivery of 10,000 tires per month. They are built on special steel rims and are intended for use on trucks at the front.

—

Bright Outlook for Electrics in Norway

CHRISTIANIA, NORWAY, June 14—That the sale of electric automobiles in Norway has a bright outlook is claimed in consular reports recently made out in Christiania. Although the country is composed of many hills, it is claimed that that type of car could be used to advantage there.

Electric power plants are not far apart in Norway, thus rendering it possible for a car to travel practically all over the country and be recharged whenever needful.

Security Changes Small

Tire Issues Lower—Changes Range from One to Five Points

NEW YORK CITY, July 5—The securities markets were in a sensitive condition throughout last week as a result of the passing of the U. S. Rubber dividend on Thursday. The markets were weak and dull. Gains were few and small, ranging up to 4 points. Losses were also small, ranging up to 5½ points.

Tire issues last week were somewhat lower, Goodrich, Goodyear and Miller Rubber issues being the only ones to show increases. Firestone after reaching a record quotation of 503 a week ago, dropped to 500 last week. Studebaker preferred managed to show a 1½ point gain. General Motors common was the only other automobile stock to show a gain, that being 4 points.

The Detroit issues were normal, the gains ranging from a fraction to 2¼ points. In the inactive stock, the Canadian Ford stock gained 275 points.

—

War Orders Increase International Motor Earnings

NEW YORK CITY, July 1—The net earnings of the International Motor Co. in the month of May are understood to have amounted to over $90,000 after deducting all interest charges. Earnings for the 5 months ending May were over $160,000, and on the present basis of business, earnings for the full year may aggregate $700,000.

This is equivalent to 19 per cent on the $3,600,000 7 per cent cumulative preferred stock, on which no dividends have been paid since September, 1912. The company has outstanding $5,628,125 common stock.

The war has been the cause of part of the improvement in business of the company, as its factories are working to capacity to turn out Saurer trucks for shipment to England, France, and indirectly to Belgium.

—

Syndicate Sells Its Stewart-Warner Stock

NEW YORK CITY, July 3—The syndicate headed by White, Weld & Co. and Hornblower & Weeks, which purchased 40,000 shares of Stewart-Warner Speedometer common stock from J. K. Stewart, president of the company, has sold all the stock, the offering price being 67.

—

U. S. L. Property Brings $1,000,000

BUFFALO, N. Y., July 1—At the receivers' sale of the U. S. Light & Heating Co. held at Niagara Falls, the stockholders' protective committee bought the property for $1,000,000.

—

Federal Truck Pays $50,000 Dividend

DETROIT, MICH., July 2—The Federal Motor Truck Co. has declared a 10 per cent dividend, aggregating $50,000.

—

Goodyear Record 15,447 Tires

AKRON, OHIO, July 3—The Goodyear Tire & Rubber Co. has broken its daily production record of 11,032 tires, having recently produced 15,447.

Georgia $5 Tax Enjoined

State and Cities Will Regulate Cars—Case Will Be Appealed

SAVANNAH, GA., July—Granting an injunction restraining the State from collecting $5 registration fee from owners of automobiles and motorcycles in Chatham County, Judge Charlton in the Supreme Court held that the city and State had a right to regulate them, but that the provision that the proceeds be distributed among counties for roads in accordance with the number of miles of rural route is invalid.

It is considered certain that the case will be appealed by the State and city. If the findings of the lower court are sustained they will next be heard by a jury, when it will be determined whether permanent injunctions shall be issued.

Judge Charlton held that in effect the law virtually double taxes owners of automobiles.

—

Licensing of Chauffeurs in Ohio Unconstitutional

COLUMBUS, OHIO, July 3—Judge Dillon in Common Pleas Court, has declared the Ohio law providing for the licensing of chauffeurs by the Secretary of State unconstitutional in the case of Joseph Dayton, charged with operating a car without a license. The case came up originally in the police court, where the law was held unconstitutional by Judge Osborn.

The court held that since the law does not fix a standard of qualification for chauffeurs it is not valid as it depends on the arbitrary wish or caprice of the Secretary of State. The case will likely be appealed to the Ohio Supreme Court for final adjudication.

—

Wisconsin Law Protects Dealers

MILWAUKEE, WIS., July 2—Wisconsin automobile dealers who sell cars on credit—and most of them do—have obtained the protection so long desired by the passage of a law by the Wisconsin Legislature, and now in effect, which makes the use of false statements to obtain property on credit a penal offense.

—

Ill. Wheel Tax a Law

SPRINGFIELD, ILL., July 3—Illinois cities now have the privilege of affixing a wheel tax to all automobiles and other vehicles if they see fit. The supreme court set aside the previous law, declaring it unconstitutional on a case appealed from Lincoln. Owing to the importance of this tax to Chicago and the larger cities, the legislature changed the law to meet the objections of the courts. The revised bill became a law when Governor Dunne signed it this week. The tax in Chicago on automobiles is $10 to $20, in accordance with the horsepower.

—

Wisconsin Licenses 77,160 Cars in 1914

MADISON, WIS., July 2—During the fiscal year of the State of Wisconsin ending June 30, 1915, a total of 77,160 licenses were issued for automobiles owned by private owners, compared with 49,625 issued during the preceding fiscal year. It is interesting to note, however, that the total 1915 registration on June 28 was 69,116, compared with 53,161 issued during the whole of 1914. On this basis the 1915 registration will exceed 75,000, the figure set at the beginning of the year, and probably run well above that. In 1914 more than 8000 cars were registered between July 1 and Dec. 31, and figuring along these lines, the 1915 total will be approximately 78,000.

—

137,383 Cars in California

SAN FRANCISCO, CAL., July 3—There are 137,383 automobiles in California. Los Angeles leads the fifty-eight counties with 46,447. San Francisco is second with 14,714 and Alameda, third, with 9417.

—

Nearly 30,000 Automobiles in Conn.

HARTFORD, CONN., July 2—There are nearly 30,000 registered automobiles in the State of Connecticut according to the new motor vehicle register which has just been issued by a private concern in Hartford. The new publication covers registrations up to June 19. Within the past 3 months 3000 cars have been registered as jitneys. This type of conveyance is said by railroad officials to be the cause of curtailment of train service throughout the State. The business of the Secretary of State's office in car registrations will be at least one-half million dollars this season.

—

Kentucky Fees $98,586

LOUISVILLE, KY., July 3—Kentucky automobile licenses collected since Jan. 1 amount to $98,586.29. January, $9,883.39; February, $12,826.60; March, $16,107.37; April, $14,556.27; May, $9,305.65, and June, $36,406.99. The law making all licenses to expire Jan. 1 went into effect last June, and so this year all licenses as they are renewed are prorated for the time until Jan. 1, 1916. Consequently the amounts of renewals are not as large by several thousands of dollars as they would be had they been for the full period of twelve months.

77,339 Cars in Canada

Commercial Cars Number 68,320—Pleasure Cars 1,155 and Dealers 1,120

TORONTO, ONT., July 3—The following figures herewith indicate the number of automobiles in Canada to date which runs over 70,000.

Province	Commercial Cars	Pleasure Cars	Dealers	Motor Cycles
Ontario	31,724	Inc.	260	3,633
Quebec	6,824	384	137	205
Nova Scotia	1,194	7	20	96
New Brunswick	1,940	25	20	70
Prince Edward I.	44	...	2	3
Manitoba	6,600	275	360	940
Saskatchewan	8,963	Inc.	124	461
Alberta	4,630	98	86	387
British Columbia	6,370	363	109	944
Yukon	31	3	2	7
Total	68,320	1,155	1,120	6,746

—

Missouri Registrations Increase 20 Per Cent Over 1914

JEFFERSON CITY, MO., July 1—An increase of about 20 per cent in the number of automobiles registered in the State of Missouri during the first five months of the current year over the same months last year is indicated in a statement issued by the Secretary of State here to-day.

The report shows that 66,061 automobiles were registered between February 6, the beginning of the registration year, and June 30. This is an increase of 11,563 over the figures for a similar period in 1914. In view of these figures, State officials predict that a total of more than 75,000 cars will be registered during the present year.

St. Louis and Kansas City respectively lead in the number of high-priced cars registered.

—

Indiana Has 81,608 Cars

INDIANAPOLIS, IND., July 3—There are 81,608 automobiles registered in Indiana, a gain of 26,608, compared with the number of registrations issued the first six months of last year, and 15,108 higher than the entire year of 1914. The receipts of the State department for the six months was $535,049. There are 650 retail automobile dealers in the State.

—

$600,000 Invested in Oregon Cars

PORTLAND, ORE., July 3—During the month ending June 15 the Oregon registrations show that, at an average of $750 per car the people of that State have invested $600,000 in machines. Nearly $20,000 a day, which is much larger than the amount expended during former years. There were 1,377 new registrations for the month. The Ford outstripped all other makes with 464.

Indianapolis Speed Amazes French

Thought Record Would Stand for Another Year—So Kept Out of Race

PARIS, June 18—Owing to the war, result of Indianapolis 500-mile race reached Paris after a delay of one week. Rene Thomas, last year's winner, is delighted at the speed attained, his only regret being that he was unable to be present.

"I am glad to hear Ralph De Palma has broken my record, and I want to congratulate him on what must have been a wonderful race. Manufacturers over here seemed to think the record would stand for another year, and on that account were not disposed to send cars. This is a lesson to them that in the racing game, progress must be constant. France had the cars and she had a few good drivers free from military service; she ought to have sent those men across, instead of being satisfied to live in the false hope that the old record would remain untouched."

As a race driver Rene Thomas was interested in the weather conditions and the make of tires used by the winner. Translated into American, Thomas's expression was, "De Palma certainly had no bum tires on his car to average nearly 90 miles an hour for such a distance."

Louis Delage, while expressing admiration at the result, appeared to be surprised and disappointed that the record of 1914 had been cut by such a big margin. The Delage chief engineer, M. Michelat, stated that if the new Delage cars had gone out they would have been sent with the intention of taking a big slice out of Thomas's old record, but he did not know enough of the track conditions at Indianapolis to predict the highest speed they could hope to make.

—

Chevrolet Cars on Indiana Tracks

INDIANAPOLIS, IND., July 3—The William Small Co., distributor for the Chevrolet car in the State of Indiana, has received two specially constructed race cars from the Chevrolet factory that will be used in State fair dirt track races throughout the State this summer. William Brown of Fort Wayne, Ind., will pilot one of the cars and the other will be driven by William Doughty of Bluffton, Ind.

—

Spokane Speedway Assn. Formed

SPOKANE, WASH., July 2—The Spokane Speedway Assn. has been organized and incorporated by a group of Spokane sportsmen. The officers of the association are A. E. Terrelle, E. F. Guerske, W. E. Camp, H. A. Holland and E. W. Stutes.

It is planned to build a two-mile speedway close enough to the center of Spokane so that it may be reached by street railways. The association has been incorporated for $100,000, with which amount it is intended to purchase the ground and construct the track. Negotiations are now pending for the property.

—

Indianapolis Show Sept. 6

INDIANAPOLIS, IND., July 5—The Indianapolis Automobile Trade Assn. will be the first organization to stage an exposition of 1916 automobiles. At a meeting held at the Hoosier Motor Club it was practically decided to hold another show at the Indiana State Fair the week of September 6.

The show will be held in a large tent covering approximately 30,000 square feet, for which a charge of 10 cents per square foot will be made members of the trade association and 20 cents will be charged those not members.

—

Wichita Show Oct. 4-14

WICHITA, KAN., July 2—The local automobile dealers will hold an automobile show in connection with the International wheat show, Oct. 4 to 14. Practically every inch of the 8800 sq. ft. of floor space was sold at a dinner given to the automobile men by the exposition committee. The exhibit will be held in a special building.

—

More Time Given Exposition Motorists

SAN DIEGO, CAL., July 1—The Panama-California Exposition officials are becoming more lenient to motorists. Automobiles are now allowed inside the fair grounds after 6 p. m.

—

Boston Races July 10

BOSTON, MASS., July 5—The automobile races scheduled to be held at the Readville track here to-day under the auspices of the Matty Matthews Racing Assn. had to be postponed because of heavy rains during the forenoon. They will be run off next Saturday afternoon.

—

Automobiles for St. Louis Mail Service

ST. LOUIS, MO., July 1—Automobiles replaced collection wagons in the complete reorganization of the mail service here to-day. On instructions from Washington the local postmaster put into the discard all but four of the wagon outfits and substituted therefor twenty-four light and fast automobiles. The few horse-drawn vehicles will be put in outlying districts when roads are bad.

Yellowstone Plans Completed

Regulations Governing Use of Cars in Park Not Yet Public

WASHINGTON, D. C., July 2—The plans for opening the Yellowstone National Park to automobiles Aug. 1 is now complete, but the regulations governing the use of machines in the park will not be made public for some time until they have been criticised by some of the officials in charge of the park. An elaborate set of rules governing the operation of cars has been compiled and while these regulations are strenuous they are considered necessary at the start. It may be several seasons before the mountain horses used in the park will be accustomed to motor traffic, and so modifications will be necessary from year to year in these regulations. The object of the stringent regulations is to guard against accidents due to the use of motor vehicles which would mar the opening of the park to automobiles.

—

Twin City Eliminations August 28-31

MINNEAPOLIS, MINN., July 3—Entry blanks are being issued by the Twin City Motor Speedway Co. for its 500-mile race in Sept. 4. The race will be under A. A. A. sanction the eliminations Aug. 28-31, with 80 m.p.h. speed for one lap of the two-mile track as the minimum. First prize is $20,000 and the remainder of the $50,000 is divided into eleven prizes from $10,000 down to $650. The three-mile fence around the grounds is erected, footings are placed for the seven grand stands and the bleachers. The grading will be completed July 15. Concrete laying began July 6 and will be completed in thirty days. Six inches of cement will be placed over 18 in. of concrete. Three hundred and fifty men are employed in the work, which is progressing rapidly.

—

Damaged Road—Fined $25

BALTIMORE, MD., July 3—The first case in Maryland of a man being charged with operating a motor vehicle without due regard for wear upon the highway was tried in Baltimore yesterday. Clarence Thornburg, a chauffeur for the Pierce-Arrow Co., was fined $25 and costs. He ran a motor truck over the asphalt of one of the main thoroughfares. Two of the wheels were without tires and the flanges cut into the paving, causing damage amounting to about $100.

Indiana S. A. E. To Study 12's

Section Will Meet September 17 —Paper by J. G. Vincent —Growth Planned

INDIANAPOLIS, IND., July 3—Thorough discussion of the twelve cylinder motor, with a paper on the subject by J. G. Vincent, vice-president and chief engineer of the Packard Motor Car Co., will feature the opening meeting of the Indiana section of the Society of Automobile Engineers, which will be held here Friday evening, Sept. 17.

Mr. Vincent is the designer of the twin-six, the first twelve-cylinder car marketed in this country, and it is of special interest to have him present a paper on that subject.

W. G. Wall, of the National Motor Vehicle Co., chairman of the committee on papers, who is also the designer of a twelve-cylinder motor, announces that he expects a large number of engineers from the various Indiana plants to be present and take active part in the discussion. Since two Indianapolis firms have already announced twelve-cylinder models, it is expected that the September meeting will be one of the most interesting that the Indiana section has ever held.

There are no meetings of the section during the summer months and the gathering in September will be the start of the regular fall and winter meetings.

The Indiana section of the society expects to expand greatly during the next few months and only recently adopted a new constitution which provided for the election of associates to the Section. This associate membership entitles the holder to all privileges of the Section, but does not make him a regular member of the national Society of Automobile Engineers.

—

Detachable Disk Wheel

PARIS, FRANCE, June 29—Michelin, the French tire manufacturer, has placed on the market a detachable disk wheel for touring car use. Owing to the war, delivery is not being made on a big scale, but a certain number of sets has been supplied for military cars and the Michelin company's touring cars and light delivery vehicles have been using these wheels for several months.

Advantages claimed for the wheel are ease of attachment and detachment, lower weight than the artillery type wheel, additional strength compared with a wood wheel, and a decided gain in the ease of cleaning compared with either wood or wire wheels. Details regarding the structure of the wheel have not been given out. It is a pressed steel type, deeply dished, and welded to the rim. It is attached by six bolts secured to the fixed hub and passing through the wheel felloe. Six nuts hold each wheel in position. Threads are cut left and right on the opposite sides of the car, so that the tendency is for the nuts to tighten up as the wheel revolves, and avoiding the use of lock washers. The Michelin bolt valve is used with the wheel, no safety lugs being employed. The valve projects on one side of the disk, thus avoiding cutting a hole in this latter. Easy washing is a feature.

—

Tires Shipped by Parcel Post

WASHINGTON, D. C., July 2—Postmaster Otto Praeger has put in a plan whereby Washington motorists when on tour can ship their tires back to Washington for repairs by parcel post. The plan was launched a week ago as an experiment and proved such a success that it has been made a permanent feature of the parcel post plan. Tires weighing 11 pounds are carried for 10 cents in the local zone, in an 8-mile radius and 15 cents for the first and second zones; the 14-pound tire takes a 12 and 18-cent rate; 17-pound, 13 and 21 cents; 21-pound, 15 and 25 cents; 22-pound, 16 and 26 cents; 30-pound, 20 and 34 cents, and 35-pound, 23 and 39 cents.

—

American Cars in Demand in British Market

LONDON, ENGLAND, June 24—The war has opened the field for American automobiles in England, where they were never able to break into the market in peace times. Now that the English government has taken over all English automobile factories, a great demand has been created for the high-priced American touring car.

An agent in this city has sold 1500 of the high-priced cars within the last 30 days and could have sold 3500 more if he could have filled the orders. He attributed it to the fact that many persons who never before have been able to afford cars are now making large sums of money from the government contracts and are spending their new wealth on automobiles and other luxuries.

—

Snyder Promoted

DETROIT, MICH., July 3—C. Snyder, who was with Chalmers for 14 years, and who was efficiency man for the National Cash Register Co., Dayton, Ohio, has been promoted to the position of superintendent of manufacturing.

—

Lazelle Marion State Sales Mgr.

JACKSON, MICH., July 3—U. E. Lazelle has been appointed State sales manager by the Marion Motor Co.

Gasoline Prices in S.W. Unsettled

Gallon Costs from 11 to 20 Cents in Western Texas— Claim Overcharge

AUSTIN, TEXAS, July 3—Inquiry among automobile tourists who have traveled through Oklahoma, Texas and New Mexico during the last few weeks reveals a remarkable lack of uniformity in gasoline prices, which cannot be accounted for by the difference in freight charges on the product, as applied to the various points. It is found that in some of the towns of western Texas as much as five cents difference in the price per gallon exists between local dealers. It is claimed by overland travelers that it is not infrequently the case that dealers take advantage of the tourist by charging an exorbitant price for gasoline and that this condition is also true of some of the garage and repair men. The price of gasoline in Texas ranges all the way from 11 cents to 20 cents per gallon. In western Texas 13 cents to 15 cents are the prevailing prices, although it is not unusual for as much as 20 cents to be charged. In New Mexico the situation is about the same as in western Texas. As an evidence of the unstability of the local markets it may be noted that one town may announce a raise of the price a cent or two per gallon to-day and perhaps another town not far away may declare a reduction. In Oklahoma the prices also show a fluctuation and a lack of uniformity which is not based on the wholesale prices or the freight rates.

The cost of gasoline is an important item to the long distance tourists and many of them object to being made the victims of exorbitant charges. What is true as to gasoline prices is also the case as to lubricating oil. A difference of as much as 25 cents per gallon in the same brand of oil in the original package is found in towns which have the same freight rate.

—

1916 Abbott 8-80 on the Market

DETROIT, MICH., July 3—The 1916 Abbott-Detroit, 8-80, an eight-cylinder, seven-passenger design manufactured by the Consolidated Car Co. of this city, has been announced and shipments are now being made. The motor is the Herschell-Spillman unit power plant, its dimensions being 3¼ by 5 with the cylinders in blocks and using the single camshaft scheme with sixteen integral cams. The cylinder blocks on this motor are staggered and instead of the forked connecting-rod, a side-by-side arrangement is employed. The crankshaft is carried on three main bearings. While

the S. A. E. rating is 33.8 hp., it is claimed by the makers that 80 can be developed on the block and a speed of 70 m.p.h. on high can be reached.

Other specifications include a Stewart vacuum feed, Duplex carbureter, Auto-Lite electric system with Remy battery ignition, disk clutch, worm and wheel steering, left drive and center control. The springs are underslung, semi-elliptic front and three-quarter elliptic rear with the perches swiveled at the axle. The final drive is through spiral type bevel gears and floating rear axle mounted on Timken axles at the differential and annular bearings at the wheels. Special attention has been given to the body which is of somewhat foreign appearance, a suggestion that is enhanced by the sloping windshield. A new one-man top is included in the equipment as is a full set of instruments on the walnut dash, German silver clock and 35 by 4½ tires, non-skid in rear. The wheelbase is 121 in. and the standard color Brewster green. The price is given as $1,950.

—

To Sell Wilcox-McKim

SAGINAW, MICH., July 3—Efforts to refinance and re-organize the Wilcox-McKim Co., which made automobile steering gears, piston rings and other parts and light machinery, having failed, the plant and its equipment will be sold, by order of the United States district court. Full particulars may be obtained from E. D. Church, trustee in bankruptcy in Saginaw.

—

New Sparton Hand Horn

JACKSON, MICH., July 3—The Sparks-Withington Co. is delivering a new hand-operated horn, Model G, which is a third larger than any other hand-operated horn. The diaphragm-vibrating mechanism is similar to that used in other hand-operated Spartons and the operating lever is pushed forward to sound the horn. The diaphragm is hand-hammered. A rigid bracket is supplied which can be screwed to any part of the car, only a screwdriver being required to put the horn in place. It lists at $7.

—

Hassler Shock Absorber Expands

INDIANAPOLIS, IND., July 3—Robert H. Hassler, Inc., the manufacturer of the Hassler shock absorber for Ford cars has fitted up a plant with complete machinery, in the Prest-O-Lite Building, 227 East South Street, this city, with a capacity of 500 per day.

—

Oakland Changes in Detroit

DETROIT, MICH., July 3—Beginning this month, the Standard Auto Co. becomes the Oakland distributor in Detroit, also Wayne, Monroe, and part of Macomb counties.

A Field for Cars Under $500

—

War Cripples Will Want Many —Hand Control a Desirable Feature

—

By H. D. Van Sant
American Consul

DUNFERMLINE, SCOTLAND, June 17—In view of the constant arrival of disabled officers and soldiers from the front, including the many with frost bitten feet and the thousands of invalids and crippled civilians in the United Kingdom, the need for a small motor or motor tricar—a good hill-climber for Scotland—at a comparatively low cost, is more apparent in this district and Scotland than ever. Something that will be safe to handle and inexpensive to run and at a cost not to exceed $500 would meet with ready sale in the near future, especially as no such machine has thus far been perfected, at least as far as the writer has been able to observe in this district. An objection to the tricar type is the added danger of skidding and overturning at sudden corners or down steep streets or hills, so frequently met with in this territory.

Hand Control a Factor

If a machine propelled without the need of foot action or guided and controlled entirely by hand could be constructed at a price within the range of the middle class or the coming pensioner, it would find an unprecedented sale in the British market in the near future.

Already several inquiries have been made at this Consulate as to whether such a motor car is being made in America and also if catalog or other information regarding one is obtainable. Recently one or two British makers have been approached on the subject and have plans under consideration for the introduction of such a machine.

If an American-made machine of the desired pattern is introduced the demand for it is likely to prove beyond the ordinary. As the war progresses, the probability of a market for such cars has been estimated at from 10,000 to 20,000 the first year.

Cars and Trucks Show Wear

Already the many motor cars and trucks in this district requisitioned by the military is beginning to show signs of wear, and the sight of machines being repaired along the roads and at the garage is more frequently noticed, a number apparently being much worse for constant use, resulting in a number of inquiries at this office for new American cars. The low priced American machines appear to be holding their own with some of the higher-priced British made cars, notwithstanding their constant use day and night since the outbreak of the war, though it is apparent that the lighter woodwork and painting and varnish of the American car suffers in comparison with the higher priced British and French makes. But in the machine itself, the average American car is holding its own, and a further market for these cheaper cars will likely increase before another year, if the stock is renewed among dealers and agents throughout this district and Scotland.

Competition Keen

The competition between the sale of British, French and American cars has been so keen that agents here have declined to accept the agency for American cars other than those already represented, until at least after the beginning of the new year, and several American makers endeavoring to enter the field with the regular dealers have been told they would have to wait another year before their claims for representation would be considered. While the demand for cars is not likely to diminish the competition is keen and spirited, with a natural loyalty and inclination for the home product when all else is equal.

Scarcity of Motor Transport Drivers in England

PORTSMOUTH, ENGLAND, June 24—The Hampshire Automobile Club has received a letter from a motor transport examining officer of the Army Service corps, drawing attention to the urgent need for an immediate increase in the number of drivers enlisting.

The supply of heavy car drivers is quite, and of commercial vehicles nearly exhausted, and the services of every private car driver are being asked for. The pay is $1.50 a day.

—

Thomas Making $4,000 Six

BUFFALO, N. Y., July 5—Under the model name of series MF, the E. R. Thomas Motor Car Co. is putting out a six-cylinder car selling for $4,000. The motor has its cylinders cast in pairs and with a bore of 4¼ and a stroke of 5½ in. is rated at 43.3 hp. by the S. A. E. rating. Other specifications include a three-speed gearset, floating rear axle with spiral type bevel gears, 37 by 5 tires, 12-volt starting, five wire wheels and full accessory equipment.

—

Walton Master Carbureter Sales Mgr.

DETROIT, MICH., July 1—A. B. Walton, who has been with the Master Carbureter Corp. since last October, has been appointed sales manager.

Make Gasoline from Natural Gas

—

Bureau of Mines Bulletin Treats of Preventing Waste of Gas in Oil Mining

NEW YORK CITY, July 2—Condensation of gasoline from natural gas is the title of a bulletin recently issued by the Bureau of Mines treating of a method of preventing the waste of natural gas incidental to oil mining. The bulletin points out that condensation methods may be made use of which offer the oil operator and others a profitable means of using some of the oil well gas now being wasted. The most desired constituent of crude oil is obtained, the production of oil is not hindered, and the gas, after the extraction of gasoline, can be returned to the leased area to drive pumps or to be put into pipe lines for uses to which natural gas is generally put. It is stated that the fuel value of the gas so returned is very little affected by the extraction of the gasoline product by means of the condensation process.

The authors of the bulletin, which is No. 88, are George A. Burrell, Frank M. Seibert and G. G. Oberfell. In this document they state that gas may be found in a sand separate from the oil; it may be found in more than one sand separate from the oil or the gas sand may be just above and in contact with the oil sand. A given sand may produce oil and gas in one place and in another part of the territory produce gas only.

Gas from Oil Sand

Gas may come from the same sand as the oil itself. It is this manner of occurrence of gas and oil that the authors desire to emphasize, for under these conditions the gas is frequently mixed with enough of the gasoline constituents of the oil to warrant the erection of a plant for the purpose of condensing the gasoline. The gas usually finds its way to the atmosphere through the space between the casing of the well and the tubing inserted for the removal of the oil. This gas is the so-called casing for the removal of the oil. This gas is the so-called "casing-head gas." At the beginning of an oil flow when the flow is natural, a large quantity of gas escapes to the air through the same tubing as the oil. Where the gas finds its exit to the atmosphere apart from the oil at the casing head it is a simple matter to make pipe connections between the casing head and any desired point where the gas is to be utilized. This is frequently done when the supply of casing-head gas is sufficient to warrant its utilization, but frequently, when the supply exceeds the small demands of the lease, the excess is wasted.

When a well is first drilled, the quantity of gas escaping with the oil from the tubing is frequently enormous, being 10,000,000 to 15,000,000 feet or more at times. As this gas is wasted, the flow in time diminishes.

When gas comes with the oil in the flow pipe, the two are often separated by means of a gas trap. The oil, entering the top of a drum, settles to the bottom and is withdrawn, and the gas flows off at the top. Many of the plants in California utilize gas that flows with the oil for condensing gasoline. One gasoline plant in the Cushing field, Oklahoma, also uses trap gas. A new type of trap for saving gas from gushers and separating the gasoline is described in this report.

Oil wells that have passed the flowing stage and are being pumped may still continue to give off much gas at the casing head. The quantity may vary from little or nothing at some wells to 500,000 cubic feet or more at others. When enough of the gas is available, it is used for pumping on the lease, the excess being wasted. A steam pumping engine of 50 horsepower requires about 25,000 cubic feet of gas for 10 hours' operation. From 12 to 15 cubic feet of natural gas is needed per horsepower-hour for gas engines that are used on leases for pumping oil wells. If there is not enough of the gas available for working pumps, it is all allowed to go to waste, or perhaps some is used for heating and lighting a few scattered houses on the lease.

The efficient utilization of the wasting casing-head gas ordinarily is a difficult problem. The many miles of pipe that would have to be laid to transport it from a field would usually be an unwarranted expense. However, some towns, among which may be mentioned Warren, Pa., and Sistersville, W. Va., are lighted and heated largely with casing-head gas.

In general, however, the oil man considers casing-head gas as waste gas and its escape necessary in oil-well operations, to permit the maximum flow of oil into the well from the surrounding strata.

The bulletin also treats of the effect of drilling neighboring wells; the effect of formation of waxy sediment; the history of the making of gasoline from natural gas; the chemistry of natural gas, and many other matters of interest along these lines.

—

Wis. Sleigh-Tread Law Repealed

MILWAUKEE, WIS., July 3—The Wisconsin Legislature has repealed the 1913 statute known as the "wide sleigh" law, providing that no sleigh could be manufactured or sold in Wisconsin after Jan. 1, 1914, unless the gage of the tread was 56 in., the gage of practically all wheeled vehicles in Wisconsin. The repeal was not opposed by motoring organizations, the belief being that no law is necessary for the use of wide sleighs. The argument in favor of the repeal was that it caused much confusion in the sleigh manufacturing trade, which has been obliged to make a special tread for Wisconsin buyers. The general opinion is that inasmuch as the advantages of the wide tread have been convincingly pointed out by two winters' use among farmers, they will not go back to the narrow tread. The repeal of the law makes the tread optional.

—

Thirty-two Louisville Jitneys Under One $5,000 Bond

LOUISVILLE, KY., July 5—Following a period of several weeks of idleness, thirty-two jitney buses have arranged for one $5000 bond, under which all will operate. This interpretation of the ordinance makes it appear that one bond serves for all thirty-two vehicles, any action against any one of the thirty-two being protected by the bond. In case of accidents or other damages, the jitneys will have to secure another bond before they can begin operations. The individual chauffeurs' licenses have all been paid in the thirty-two cases.

—

3½-Cent Jitney Rides

CPOKAN, WASH., July 3—Three-and-one-half-cent-fare automobiles began operating on the Spokane streets yesterday. The cars seat ten passengers. Books containing tickets for 100 rides are being sold for $3.50.

—

Bowser Receives Exposition Award

SOUTH BEND, IND., July 3—The International jury of awards of the Panama-Pacific International Exposition awarded to S. F. Bowser & Co., Fort Wayne, the grand prize, and also a gold medal on the company's self-measuring pumps and storage tanks.

—

Stoops Manages Vanguard

DETROIT, MICH., July 3—H. J. Stoops has been appointed general manager of the Vanguard Manufacturing Co., manufacturer of windshields. Mr. Stoops was formerly with the Trumbull Cyclecar Co., and the Detroit agency of Emil Grossman.

—

Thomas Resigns from Dauch

SANDUSKY, OHIO, July 3—F. W. Thomas has resigned as chief engineer with the Dauch Mfg. Co., to take the position of chief engineer and factory manager with Clark Engine & Boiler Co., Kalamazoo, Mich.

Factory Miscellany

Perry Top Moves—The Perry Auto Top Co., Columbus, Ohio, has removed to a large factory at 220 North Third Street.

Mogul Truck Builds—The Mogul Truck Co., 6100 Maple avenue, St. Louis, Mo., has bought a site 125 by 187 feet and will erect a plant for the manufacture of trucks.

Leather Co. to Build—The Lackawanna Leather Co., Hackettstown, N. J., manufacturer of automobile and carriage leathers, will build a two-story addition to its plant.

Detroit Steel Adds—The Detroit Pressed Steel Co., Detroit, Mich., will spend about $25,000 for the erection of a two-story office addition, 56 by 130 feet, and a one-story steel frame factory addition, 57 by 185 feet.

Ford Lets Contract for L. I. Plant—Ford Motor Co., Detroit, has let a contract for an eight-story, 200 by 325-foot assembling plant in Long Island City, N. Y., plant having been under contemplation for some time.

Fisk Rubber Adds—The Fisk Rubber Co., Chicopee Falls, Mass., has awarded the contract for the construction of a 50 by 160 ft. office building, a 110 by 310 ft. storehouse and a 60 by 100 ft. garage. The estimated cost is $400,000.

Standard Four Tire to Move Plant—The Standard Four Tire Co., Marion, Ind., will remove its plant to Keokuk, Iowa, where $20,000 has been subscribed to secure the business. A factory will be constructed with an annual capacity of 60,000 tires.

Hamilton-Beach to Add—The Hamilton-Beach Mfg. Co., Racine, Wis., a large manufacturer of small electrical appliances, specialties and novelties, is having plans made for an important factory addition, to be 3 stories high, 50 by 250 feet in size, and cost about $30,000.

Louisville Ford Plant to Move—The Ford Motor Co. will move into its new assembly plant, Third and Railroad Crossing, Louisville, Ky., about Oct. 1. The present salesroom, now located at 931 Third Street will be vacated and the office force and show room transferred to the new building.

To Make Trailers—The Mountain Trailer Co., Spokane, Wash., has been organized by J. O. Mountain of the Diamond Carriage Co., A. H. Herta of the Signal Truck Co. and M. D. Hawkins of the Hawkins Motor Car Co. to construct a plant in Spokane to manufacture a patented trailer to hook onto an automobile.

To Manufacture Tires—The plant of the former Swift Automobile Co., Wayne, Mich., has been purchased for $13,000, it is stated, by the Automobile League of America, Detroit. The factory building is to be equipped for the purpose of manufacturing tires which are to be sold exclusively to the members of the league.

Hayes Wheel Enlarges.—The Hayes Wheel Co., Albion, Mich., which makes the hubs for the wheels made by the parent plant, the Hayes Wheel Co., in Jackson, will erect a new plant to be ready for occupancy Sept. 1. When completed the company will employ 200 men here, or double its present working force, and the production will be more than doubled. Machinery valued at $15,000 has already been purchased and by the time the new building is ready it is expected that from $50,000 to $60,000 will have been spent.

Four Wheel Drive Adds to Shop—Work is well under way on a large shop addition to the works of the Four Wheel Drive Automobile Co., Clintonville, Wis., which is working on large war orders for its quadruple drive trucks. The company is so busy turning out army cars that its domestic demand can hardly be met, and no orders are being taken for quantities until the trucks purchased by the Imperial Russian government and other European nations are delivered.

Trained Help Hard to Get—The Kissel Motor Car Co., Hartford, Wis., in common with other industries in the automobile and allied metal working trades, is experiencing difficulty in getting sufficient trained help to meet its needs. The company is advertising in the metropolitan papers for experienced machinists for milling machines, universal grinders and drill presses. All around machine hands are preferred. There is a scarcity of skilled workmen in many lines.

Will Enlarge Plant—The Empire Rubber & Tire Co., Trenton, N. J., is to inaugurate alterations and extensions in its plant with the idea of increasing production and of improving the facilities for handling it. One new building is in the course of erection at the present time. A siding is also being run from the tracks of the Pennsylvania Railroad direct to the shipping room. Changes and improvements to be made in the shipping room will mean a big facilitation in delivery. The need of extra room is demonstrated by the fact that in the tire building department the men are being worked in three 8-hour shifts.

The Automobile Calendar

July 9	Burlington, Ia., 100-Mile Track Race; Tri-State Fair.
Aug.	Milwaukee, Wis., Independent Petroleum Marketers' Assn. of the U. S.; 1915 Convention in Milwaukee.
Aug. 2-3	San Francisco, Cal., Tri-State Good Roads Assn., Third Annual Convention.
Aug. 20-21	Elgin, Ill., Road Races.
Aug. 30	Columbus, O., Show, Ohio State Fair, Columbus Auto. Show Co.
Sept.	Indianapolis, Ind., Fall Show, Indiana State Fair.
Sept.	Peoria, Ill., Second Northwestern Road Congress.
Sept. 6	Providence, R. I., Speedway Race; F. E. Perkins.
Sept. 6	Detroit, Mich., Speedway Race; Detroit Speedway Club.
Sept. 6	Indianapolis, Ind., Show, Indiana State Fair.
Sept. 8-11	Hamline, Minn., 2-Day Meet at State Fair Grounds between Minneapolis and St. Paul, State Fair.
Sept. 13	Oakland, Cal., Pan-American Road Congress.
Sept. 17-18	Peoria, Ill., Illinois Garage Owners' Assn. Convention.
Sept. 20-25	San Francisco, Cal., International Engineering Congress.
Sept. 18-25	Los Angeles, Cal., Show, Shrine Auditorium.
Oct.	St. Louis, Mo., Show, Forest Park Highlands, St. Louis Automobile Manufacturers and Dealers' Assn.
Oct. 1	Minneapolis, Minn., Track Race, Twin City Motor Speedway Co.
Oct. 1-2	Trenton, N. J., Track Races; Inter-State Fair.
Oct. 2	New York City, Sheepshead Bay Motor Speedway Track Meet.
Oct. 6-16	New York City, Ninth Electrical Exposition and Motor Show at Grand Central Palace.
Oct. 9	Chicago, Ill., 300-Mile Race.
Oct. 11-12	Dayton, O., National Paving Brick Manufacturers' Assn., Annual Meeting.
Nov. 18	Arizona 150-mile Grand Prix.
Dec. 31	New York City, Show; Grand Central Palace.
Jan. 22, 1916	Chicago, Ill., Show; Coliseum.
March 4-11	Boston, Mass., Truck Show, Mechanics Bldg.

The Week in the Industry

Nelke Takes on Oakland—A. W. Nelke, who handled the Overland in Western Maine for some years, has given it up and he now has the agency for all Maine for the Oakland. He is making his headquarters at Lewiston.

Peck Resigns—W. V. Peck, formerly Chicago representative of the Pittsburgh Model Engine Co., Pittsburgh, Pa., is no longer connected with the company. Hereafter the sales in Chicago and vicinity will be handled direct from the plant.

Caten Makes a Change—E. L. Caten, who was identified with the Buick in Worcester, Mass., for some years has taken over the agency for the Paige Detroit in that city, and a company has been formed with J. H. and W. A. Stratton as partners.

Sommerville General Mgr.—A. G. Sommerville has bought the controlling interest in the Argonaut Motors Co., San Francisco, Cal., and will hereafter act as the general manager. This concern distributes the Stearns and Pathfinder in Northern California.

Parker Heads Hartford Olds.—Representation of the Oldsmobile is now vested in the Parker Oldsmobile Co., Hartford. F. R. Parker of New Haven, is the head of the concern. W. G. Murray, formerly with the sales department of the Palace Auto Service Co., has joined the Parker company.

Morrison Heads Louisville Co.—The Louisville Speedometer Co. has opened a service station for Stewart speedometers and Warner autometers at 935 Third Street, Louisville, Ky. J. H. Morrison, head of the concern, formerly was manager of the service department of the Stewart-Warner Indianapolis branch.

Banks Ford Louisville Manager—Clarence Banks, assistant manager of the Louisville branch of the Ford Motor Co. for several years, has been appointed manager, succeeding F. H. Peabody. Mr. Banks formerly had the Ford agency in Louisville, but became associated with the Ford company's Kentucky branch when it was established in 1911.

Stockwell Heads Power Gas Co.—The Power Gas Products Co., capitalized at $125,000, has been reorganized. A branch is in Detroit, Mich. The company makes automobile chemicals. Officers are: President, S. A. Stockwell; vice-president, E. H. Sherwin; secretary, C. F. Heberle; treasurer, J. S. Calder; directors, T. O. Ofstun of Glenwood, Minn.; A. J. Edwards, and George Wollman, sales manager at Detroit.

Motor Men in New Roles

DeVoe Chevrolet Pacific Representative—N. DeVoe, formerly well-known and associated with the trade in Portland, Ore., is now Pacific Coast representative for the Chevrolet.

Snow in Charge—R. H. Snow is now in charge of the truck department for the Western Motors Co., Spokane, representatives of Stewart trucks.

Bury Makes Change—F. J. Bury, formerly connected with the Packard Motor Car Co.'s service department at Detroit, is the new assistant manager of the Southern Motors Co., Louisville, Ky.

Cotton Joins Saxon—Clifford C. Cotton has been appointed special city sales representative of the Saxon car in Toledo, Ohio. He was formerly connected with the Stalker Advertising Agency.

Cronkhite with Philadelphia Oakland.—W. D. Cronkhite has been appointed district representative with headquarters in Philadelphia by the Oakland Motor Co. He was at one time connected with the Buick company.

Huntley Succeeds Histed—R. D. Huntley has succeeded J. R. Histed as manager of the J. I. Case branch in New York City. Huntley was formerly in charge of the Peoria, Ill. branch. A. G. Kellam has succeeded Huntley at Peoria.

Gargett Cleveland Mgr.—R. B. Gargett, formerly connected with the Motor Tire & Supply Co., Cleveland, has been made manager of the Electric Equipment Co., Cleveland distributor for Ohio for Westinghouse starting and lighting apparatus.

Gogarn Takes on Mitchell—J. W. Gogarn, who was identified with the Reo in New York for some years and has been agent for Ajax tires in New Haven, Conn., for more than a year, has branched out and taken on the agency there for the Mitchell line.

Selleck Joins Strauss Service—G. K. Selleck has been added to the forces of the Strauss Service Systems in Indianapolis, Ind. Mr. Selleck will have charge of the rim department of the Strauss company, and will be manager of the rim department.

Newsum Tire Service in Louisville—Thornton Newsum, of Memphis, Tenn., who operates a string of ten tire establishments in a number of large cities, has entered the Louisville field and opened a store, known as Quick Tire Service, at the Northwest corner of Third Street and Broadway. Mr. Newsum is president, C. T. Ballard, Jr., secretary, and R. E. McCaugh manager.

Irwin Goes to Portland—J. H. Irwin, formerly of Seattle, will take charge of the sale of Kelly-Springfield tires in Portland, Ore., which are handled by the Oregon Motor Car Co. M. L. Gallagher has been promoted to the position of sales manager for the Oregon Motor Car Co., succeeding D. C. Warren.

Kessler Joins Brooklyn Packard.—S. W. Kessler, who has been for several years sales manager for the I. S. Remson Automobile Co., Abbott-Detroit, and Westcott distributor in Brooklyn, N. Y., has joined the sales force of the Brooklyn branch of the Packard Motor Car Co. of New York. He will be a special sales representative.

De Vaux Takes Chevrolet Agency—Norman de Vaux, for many years past head of the Reo Pacific Co., California distributor of the Reo line, is no longer distributor of the Lansing car in San Francisco. He has taken over the coast agency of the Chevrolet car. He will change the style of his firm to the Chevrolet Car of California. De Vaux has taken with him most of his agents that handled the Reo line.

Teague Makes Milwaukee Connection—R. N. Teague, for eight years associated with agencies in Milwaukee, has purchased an important interest in the Milwaukee Motor Sales Co, Milwaukee, Wis., and upon its reorganization was elected secretary, treasurer, and general manager. The company is State agent for the Lewis VI and was recently named general agent for Milwaukee County for the Oakland. The garage and offices are at 239-241 Wisconsin Street.

Bush Resigns from Velie.—R. R Bush, who joined the Velie Motor Vehicle Co., Moline, last August, as sales manager, and was later made general manager of the company, has resigned his position and will leave shortly for Kansas City where he will engage in the automobile business for himself Mr. Bush has associated with him in his new venture W. H. Morgan, who came to the Velie company with Mr Bush and was appointed local territory sales manager. The new Kansas City firm will be known as the Bush-Morgan Motor Co., Inc., and quarters at 152 Grand Avenue, have been secured. Mr Morgan has been succeeded by H. J Daniels. The successor to Mr. Bush has not been decided on as yet.

VOL. XXXIII NEW YORK—THURSDAY, JULY 15, 1915—CHICAGO No. 3

The AUTOMOBILE

Willys Starts New Knight Régime

Elyria Plant Builds All Knight Motors—Chassis Assembled in Toledo—Four-Cylinder Car at $1,095—One Chassis and Four Body Types

FOR the first time in the history of the automobile industry, a car with a non-poppet-valve engine is to be produced in quantity. It has remained for John N. Willys, the mainspring of the Willys-Overland Co., Toledo, Ohio, to see the possibilities of the Knight sleeve-valve motor as a production proposition, and his plan to popularize it is revealed in the new Willys-Knight car at $1,095.

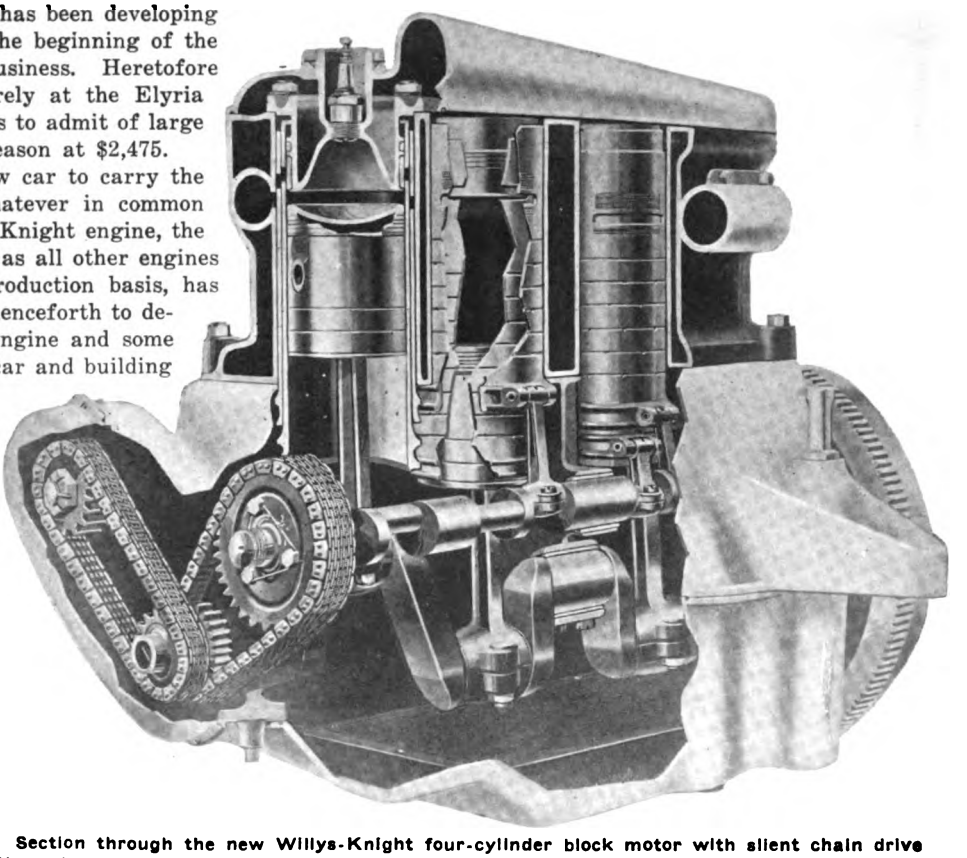
Although this is not the first sleeve-valve car to be built by the Willys organization, which really has been developing the Knight motor since 1913, it marks the beginning of the type as a big factor in the Overland business. Heretofore the Willys-Knight cars were built entirely at the Elyria factory, and their design was not such as to admit of large quantity output. They were sold last season at $2,475.

But all this is changed now. The new car to carry the name of Willys-Knight has nothing whatever in common with former cars of that name. A new Knight engine, the same in basic construction and principle as all other engines of the type, but brought down to a production basis, has been developed, and the Elyria plant is henceforth to devote its entire energies to making the engine and some of the parts with the assembling of the car and building of the chassis to be done in Toledo.

Nor do the present rather extensive production plans represent a finality as to the sleeve-valve car output as a part of the factory's production. In fact, the coming season's activities with the Knight-motored car are regarded as merely the beginning of this model with the Willys organization. A separate branch of the factory, known as the Willys-Knight division, has been formed, and it will handle the affairs of the sleeve-valve car separately.

The connection of the Willys-Overland Co. with the Knight engine goes back to 1912 and 1913 when Mr. Willys met Charles Y. Knight. Mr. Willys was skeptical of its merits, and it was not until after he had taken a trip through Europe in a Knight-motored car that he became convinced of its value.

The new Willys-Knight engine, one of the lightest sleeve-valve types yet produced, is 4⅛ by 4½. The rating given is 40 hp. and the power curve shows this obtained at 1400 r.p.m. With no falling off in power, the power curve is



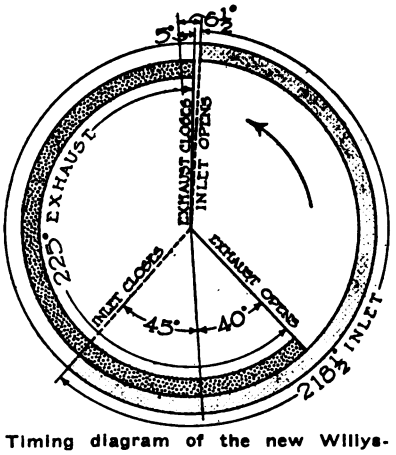
Section through the new Willys-Knight four-cylinder block motor with silent chain drive through the eccentric shaft. This motor gives 50 hp. at 2000 r.p.m. The bore is 4⅛ and the stroke 4½ in.

practically straight reaching 50 hp. at 2000 r.p.m., and at 1000, delivering 29. The precision method of valve actuation has much to do with the steady increase. The cold compression of the engine is 75 lb. per sq. in.

Cylinders Block Cast

In outward appearance it is not unlike many of the clean-cut poppet types now being built. The cylinders are cast in a block and are carried on a two-part aluminum crankcase. In Knight engine building, this is the third design to be made with the cylinders in block, and the production advantages are at once apparent. Thermo-syphon cooling is used and here again there is only one other example. There is a separate aluminum plate covering the top of the cylinder block, forming the top of the waterjacket of the heads and the outlet to the radiator. It is held in place by four nuts which screw down on the tops of the cups in which the spark plugs are placed.

By the method of using the plate as the top of the waterjacket, it is possible to have the waterjackets around the cylinders communicate with the heads of the cylinders, which are individually detachable, as in all Knight engines. In many of the designs, the heads are jacketed separately, and external piping is used to communicate between the two portions holding water. By the Willys construction, water circulates all around the spark plug seat and entirely around the domed cylinder head.



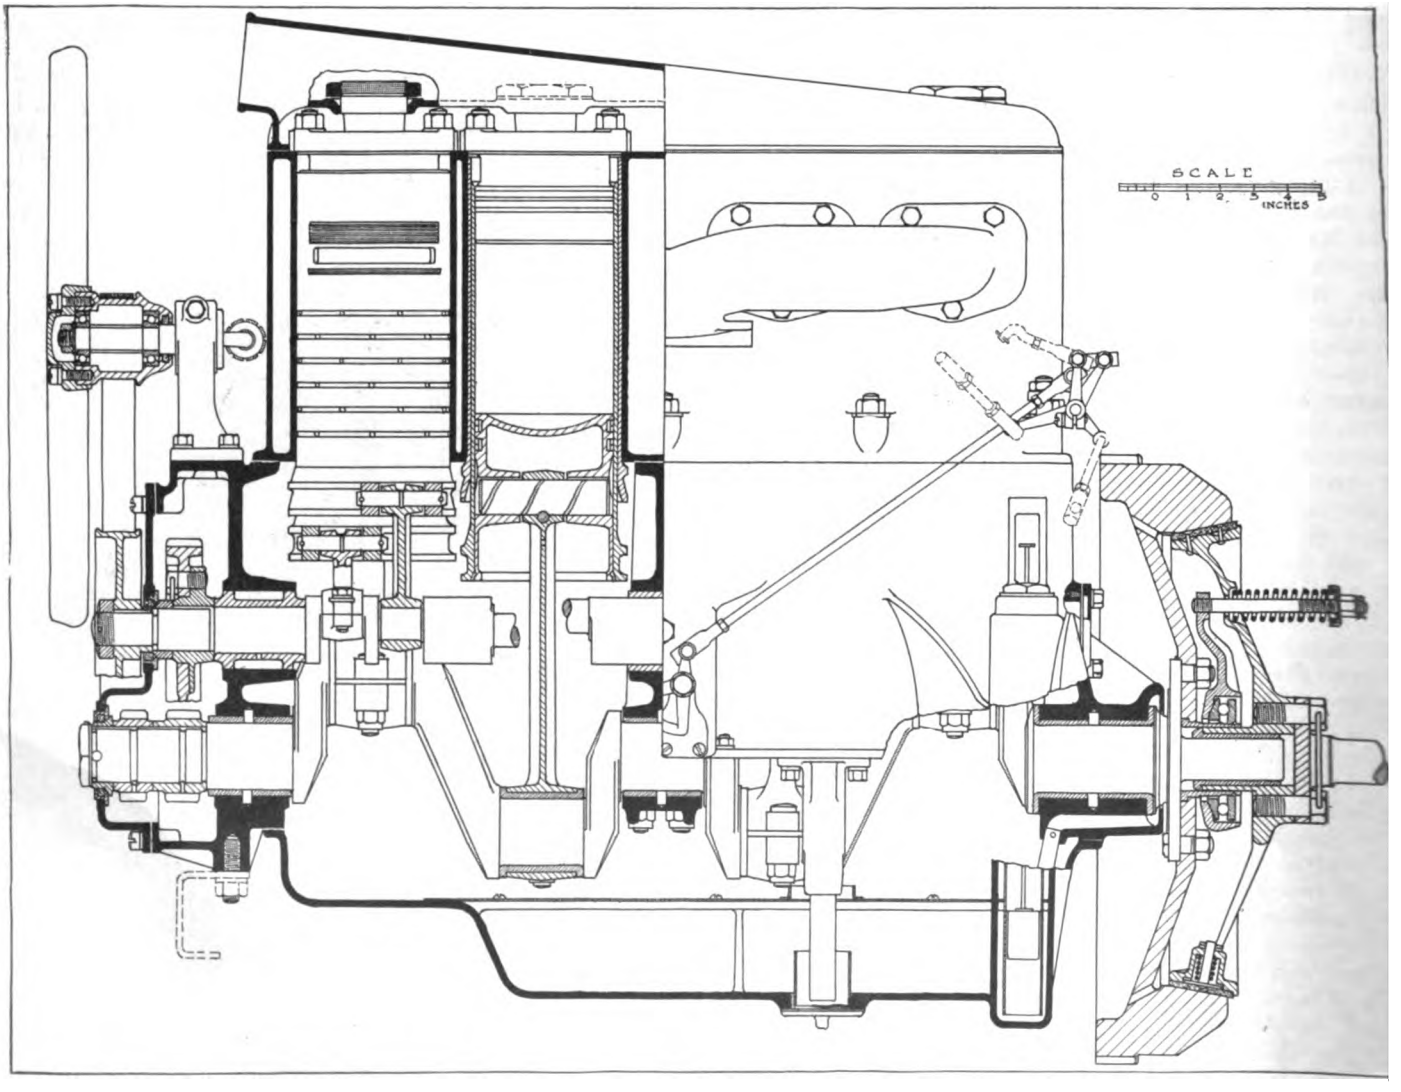
Timing diagram of the new Willys-Knight block motor

In designing the cooling system, one other point stands out of special importance, and that is the provision for draining the cylinder heads. The head is so shaped that the water syphons from it when the system is emptied. This operation is automatic, and obviates the necessity of removing the heads to get rid of the water when necessary.

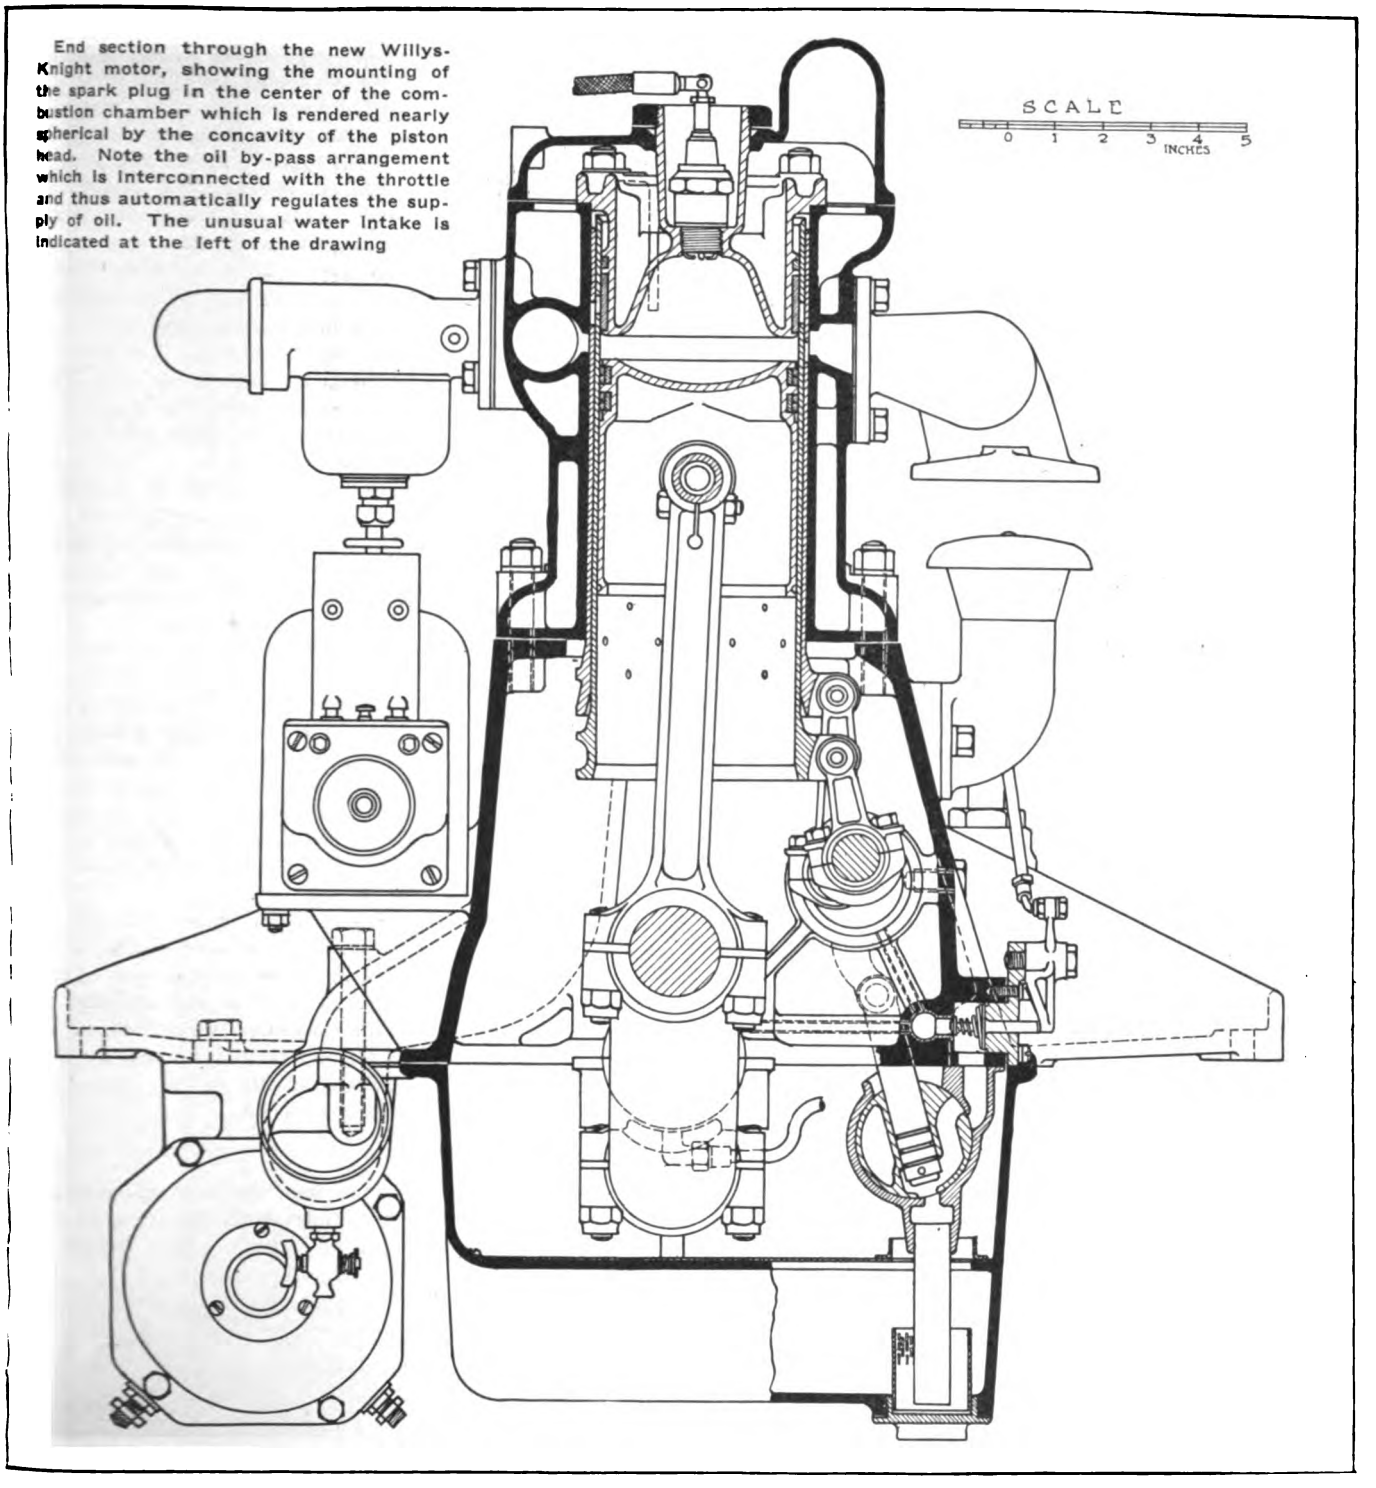
The water inlet connection is also unusual in that the inlet pipe from the bottom of the radiator attaches to the lower part of the right side of the upper half of the crankcase. An integral passage in the case leads the water vertically upward to an opening in the bottom of the cylinder casting. The water is thus introduced to the cylinders at the mid-point of the block length, making for equal distribution in either direction, and allowing for the complete surrounding of the cylinders with water throughout their entire length.

Arrangement of Ports

There is nothing unusual in the working out of the details of the two sliding sleeves and their actuation from an eccentric shaft through the intermediary of short connecting-rods.



Part transverse section through the new Willys-Knight motor, showing layout of crankshaft and also a sectional view through the cl



End section through the new Willys-Knight motor, showing the mounting of the spark plug in the center of the combustion chamber which is rendered nearly spherical by the concavity of the piston head. Note the oil by-pass arrangement which is interconnected with the throttle and thus automatically regulates the supply of oil. The unusual water intake is indicated at the left of the drawing

between the piston and the cylinder wall there are two sleeves, one within the other.

Near the top of each sleeve there are rectangular ports extending part way around the circumference and on opposite sides. In the side of the cylinder there are corresponding slots, that on the left communicating with the exhaust manifold, and on the right with the intake. When, in the slow up and down movement of the sleeves, the slots on the right side of the sleeves register with the opening in the cylinder wall, the intake port is open and there is a clear passage from the manifold to the inside of the cylinder, through the two sleeves. Thus, the three slots in the right side of the cylinder block and sleeves form the intake port, and when they come together the action is the same as when the valve of a poppet motor is raised by the cam.

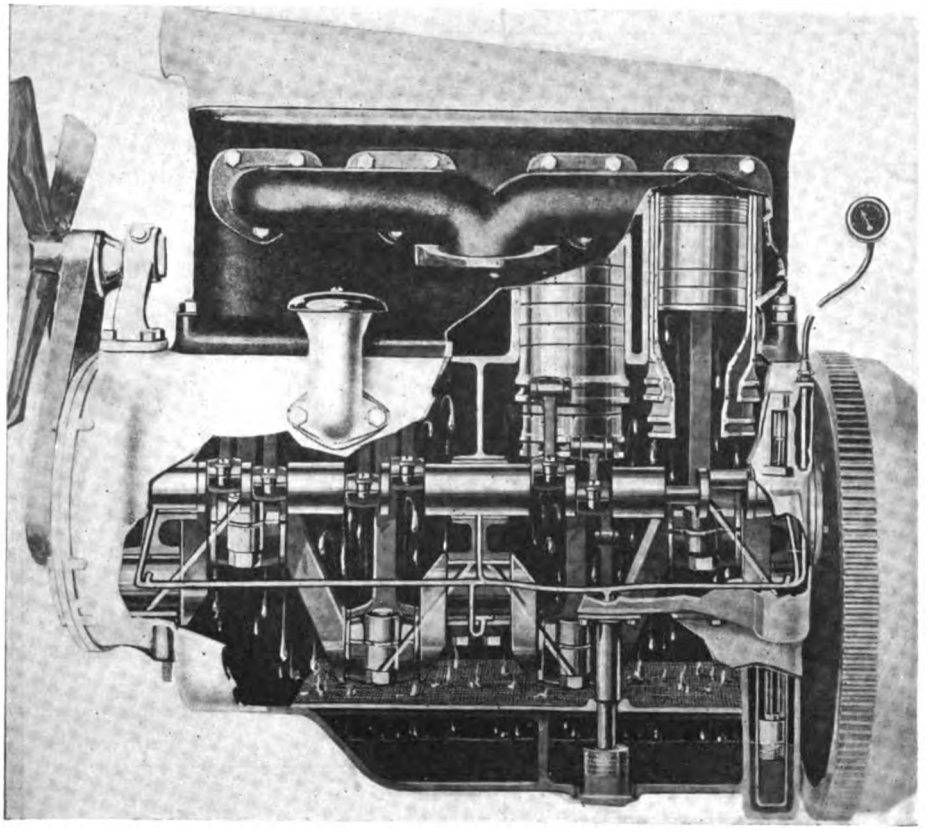
The area of the intake port measures 1.372 sq. in. Its circumferential length is 4 in. and its width is 0.393 in.

The exhaust port is 3¾ in. long circumferentially and 0.410 in. wide, giving an area of 1.5875 sq. in., the exhaust port being larger to give free outlet for the burned gases.

Sleeve Travel

The sleeves travel 1 in. at one-half the motor speed. Since the piston stroke is 4½ in., this means that the sleeves travel at only one-ninth of the piston speed, in other words, if the motor is running at 900 r.p.m., the sleeves are only traveling at a rate at which the pistons would travel when the engine is turning over at 100 r.p.m.

The eccentric shaft is driven at one-half the speed of the crankshaft by a silent chain at the front from the crankshaft and from the foregoing it is shown that the opening and closing of the valves cannot vary, but they are operated



Details of lubricating system. Note that the usual splash troughs under the cylinders are absent. The sleeves are grooved and also drilled with 1-8-in. holes at intervals to insure lubrication. Intake vacuum suction tends to lift the oil up between the sleeves

entirely mechanically, differing from the poppet valve which is closed by a spring. Therefore, no matter what the speed of the engine, there is no chance for the sleeves to get out of time, once they have been properly set. This is one of the strong claims of the Knight design, namely, that at speeds running well up over 2000 r.p.m. a proper mixture is obtained, due to the positive opening and closing of the ports in fixed relation to the movement of the pistons.

The exhaust opens 40 deg. before lower dead center, and closes 5 deg. after upper dead center.

The intake opens 6½ deg. after upper dead center, and it is closed 45 deg. after lower dead center. The diagram shows this timing, and indicates the long duration of the valve opening. The exhaust valve is open for 225 deg. of the revolution, and the intake is open for 218½ deg.

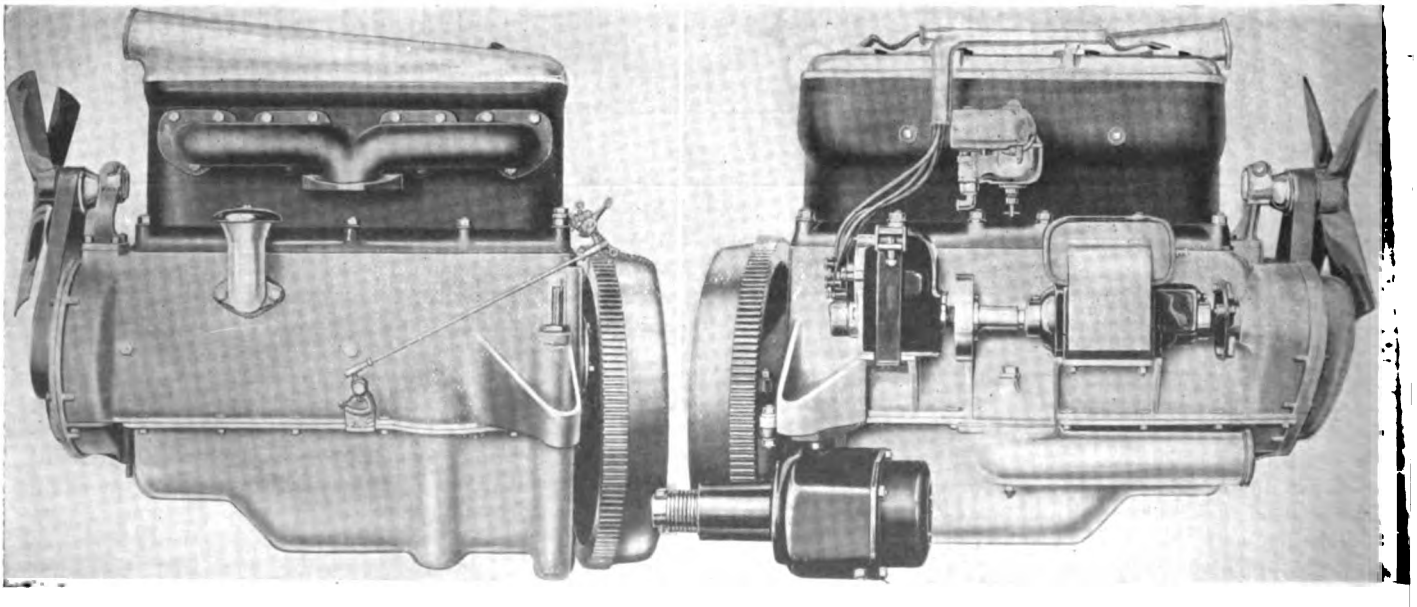
In the design of the sleeves and the rest of the moving parts there is little to distinguish this engine from other Knight types. There are junk rings, so called, between the removable cylinder heads and the inner sleeves so as to prevent the loss of compression through leakage between these two contact surfaces. The sleeve slots are unobstructed, making a free passage for the gases. The compression is held by the junk ring pressing against the inner sleeve and is in no way dependent upon the fit of the sleeves.

From the standpoint of assembling and dismantling, the method of holding the pins used for attaching the connecting-rods to the sleeves is of interest. A small spring ring is fitted to the pin, and when it is slipped through the sleeve bosses and the head of the rod, this ring springs into a groove in the inner surface of the top of the rod end. This groove is open at the top, so that in order to take the pin out, all that is necessary is to use a screwdriver or similar tool to press down on the spring ring until it clears the rod slot, when the pin can be slipped out.

The crankshaft is carried on three main bearings and is of conventional type. Pistons have concave heads, so that a nearly spherical combustion chamber results, due to the piston head shape and the domed form of the cylinder heads. The spherical chamber is the theoretically perfect shape, and the Knight motor affords an opportunity of coming close to it. The spark plug is placed directly in the center of the head, and in a cup already mentioned.

Individual Exhaust Outlets

The exhaust manifold is a separate casting with an individual outlet from each cylinder with the idea of getting rid of the gases as quickly as possible. The intake mani-



Exterior views of both sides of Willys-Knight motor, showing extreme neatness and simplicity of design

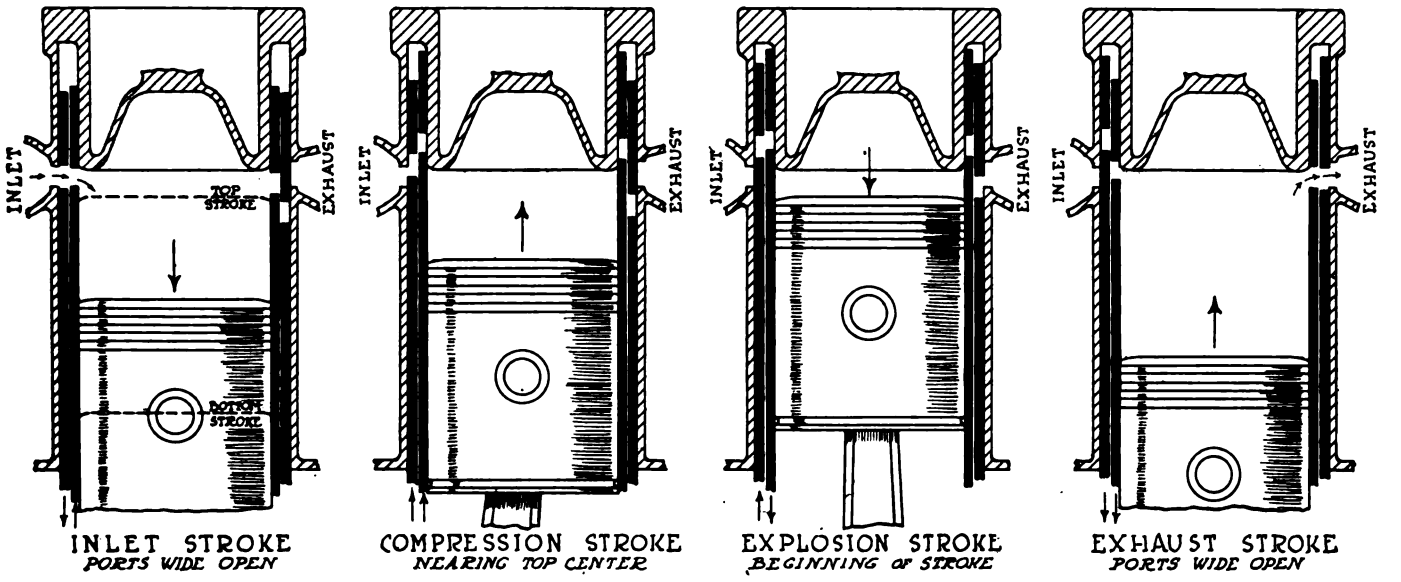


Diagram of sleeve operation at different points of the cycle on the new Willys-Knight four-cylinder block motor

fold is within the cylinder block, no part of it being exposed, the carbureter bolting directly to the casting. Its position is quite high on the block, almost opposite the valves, and this is possible due to the use of the Stewart vacuum fuel feed arrangement.

Lubrication System Simple

Simplicity has been the aim in the designing of the lubricating system. It is called a force feed and splash arrangement. The oil is drawn up from the oil reservoir at the bottom of the crankcase by a unique pump operated from the eccentric shaft and is forced through oil pipes to the crankshaft main bearings, eccentric shaft bearings and chains at the front. The crankshaft webs are drilled, conveying it to the lower rod bearings and the overflow from these is thrown into the sleeves and pistons. Thrown against the skirt of the sleeves, it is carried up between the sleeves through their own action. Circular grooves cut in the outside of each sleeve catch the oil and lift it up, distributing it as the sleeves travel up and down.

Sleeves Drilled for Oiling

The sleeves are drilled with ⅛-in. holes at certain intervals, allowing the oil spray below the piston to pass through the inner sleeve to aid lubrication between the sleeves, and also to pass through the outer sleeve to aid in lubricating the contact surface between outer sleeve and cylinder wall. Suction caused by the intake vacuum tends to lift the oil up between the sleeves, doing its part in assisting the oiling.

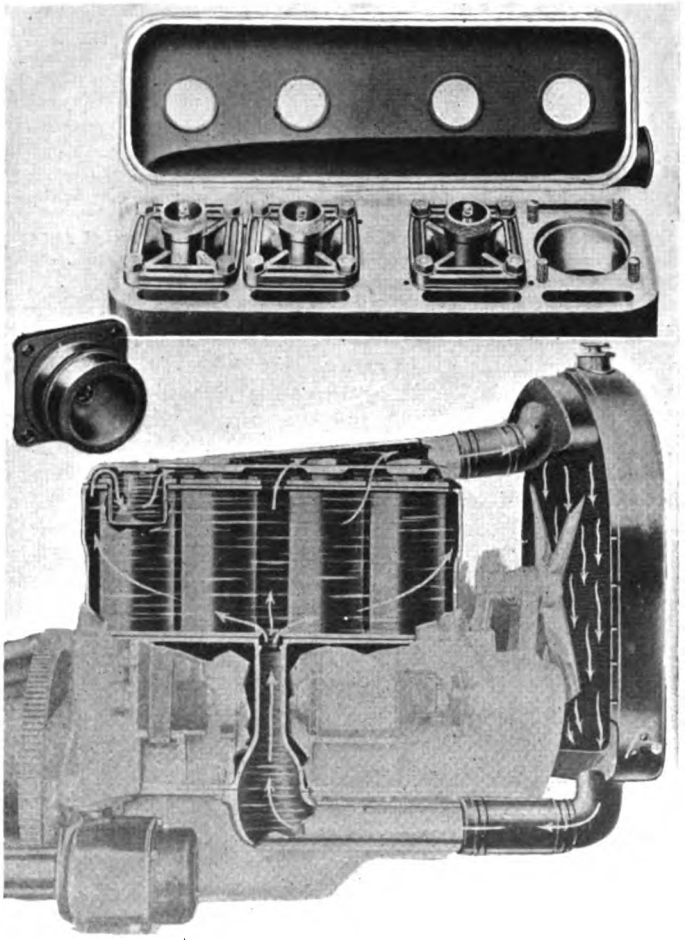
Throttle Regulates Oil Supply

The flow of oil is automatically taken care of by interconnection of an oil by-pass with the throttle. Thus the amount of oil supplied is in proportion to the throttle opening. The pump is so constructed that its entire barrel oscillates as it pumps. This oscillation is taken advantage of to uncover intake and outlet passages, so that no valves are required in the pump, making a simple and efficient device.

The Electric Equipment

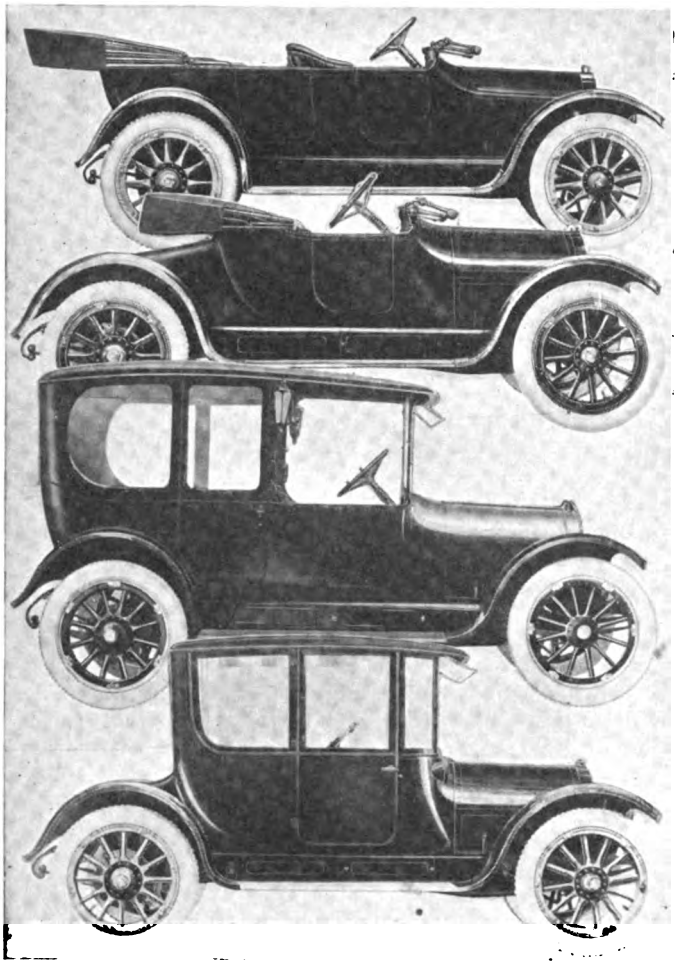
On the right side of the engine are the three electrical units, providing for ignition, starting and lighting. A silent chain, outside of the eccentric-shaft chain, drives the generator shaft at engine speed, and back of the generator is the magneto, both resting on brackets on the crankcase. The starting motor is hung below the right rear supporting arm, and it drives the flywheel through the Bendix connection, which is applied similarly to the other Overland model.

Throughout the chassis and bodies standard Overland practice as used on the six is followed. The drive is through a cone clutch and three-speed gearset to a floating rear axle. The drive shaft, fitted with a universal at the front end, is inclosed within a torsion tube which attaches at its rear



Upper—Illustrating the detachable cylinder head construction of the new Willys-Knight motor and also showing the upper part of the spherical combustion chamber formed by the detachable cylinder head. The cover plate acts as the top of the waterjacket

Lower—Phantom view through the new Willys-Knight engine showing the operation of the water-circulating system



Top—The new Willys-Knight five-passenger touring car selling for $1,095

Lower middle—Seven-passenger limousine priced at $1,750
Bottom—Coupé model marketed for $1,500

end to the gearbox. The latter is attached to the rear axle which is a characteristic of cars of this make.

The rear suspension is by three-quarter elliptic springs which are underslung from the axle tubes. These springs measure 48 by 2 in., while the front half-elliptics are 36 by 1¾ in. Brakes have plenty of power for the car, the drums having a 14-in. diameter with a width of 2¼ in.

Principal Bearing Dimensions

	PISTON	INNER SLEEVE	OUTER SLEEVE
Length connecting rod bearings (center to center)	10	2 3/16	3¾
	FRONT	CENTER	REAR
Length crankshaft bearings	2½	2½	3 11/16
Diameter crankshaft bearings	2	2	2
Length eccentric shaft bearings	2¾	2⅛	2⅛
Diameter eccentric shaft bearings	1⅝	2	2

One Chassis—Four Body Types

All four of the body types, namely, touring car, roadster, coupé and limousine, are fitted to the one chassis, whose wheelbase is 114 in. Bodies follow out the same general lines as others of this make. The upholstering is of leather, and doors are made wide and fit well into their panels. The fenders are crowned, which is always a point that adds to appearance. For the finish, royal blue with ivory striping has been decided upon as standard. Wheels are gray with fenders and trimmings of black enamel.

The touring car is the only one of the types which sells for $1,095. The roadster is still less, priced at $1,065, while the coupé is $1,500 and the limousine, a seven-passenger design, is $1,750. Needless to say, each car carries complete equipment with the open models fitted with 34 by 4 tires, non-skids in the rear, and the closed cars mounted on 35 by 4½'s, non-skid all around.

To Issue Circular on Rubber Testing

WASHINGTON, D. C., July 10—The Bureau of Standards, Department of Commerce, is about to issue the third edition of a circular on the testing of rubber goods. This publication, which has been very much enlarged, is fully illustrated, and describes in detail the method of procedure in conducting physical and chemical tests of rubber. The testing machines and apparatus developed at the bureau greatly facilitate the testing of rubber, and the object of this circular is to assist manufacturers and consumers in establishing standard specifications and standard methods of test. The subject matter proper is introduced by a brief outline of the processes through which rubber passes before reaching the factory, followed by a short description of the usual processes of manufacture, which include washing, drying, compounding, "making up" various articles, and vulcanizing. The physical tests most commonly employed are explained very thoroughly. These include tests for tensile strength, ultimate elongation, and elasticity. Conditions affecting the results of tests are discussed at some length and experimental data are given to show the necessity of a standard procedure in testing.

A general discussion of the chemistry of rubber is followed by a brief explanation of the object of each of the analytical determinations that are commonly made. After this are given the methods in use at the bureau.

Packard Twelve Makes 72.7 M.P.H. on Chicago Speedway

First Manufacturer's Test on New Board Track Shows 13.3 M.P.G. for Twin-Six in 50-Mile Economy Test—69.8 M.P.H. with Seven Passengers and Top Up

CHICAGO, ILL., July 10—The first use of the Chicago 2-mile board speedway for testing by manufacturers took place to-day when the Packard Motor Car Co. tested its new twelve for economy, speed and other factors, the test being made under the supervision of the American Automobile Assn. with its officials, timers and starters.

The first test to be made was for economy. In a 50-mile run, with top down and windshield up, carrying five passengers, the new Packard twin-six consumed 3 gal., 95½ oz. of gasoline, averaging for the 50 miles, 13.3 miles per gal. The weight of the car with the passengers was 5400 lb.

72.7 M.P.H. for 10 Miles

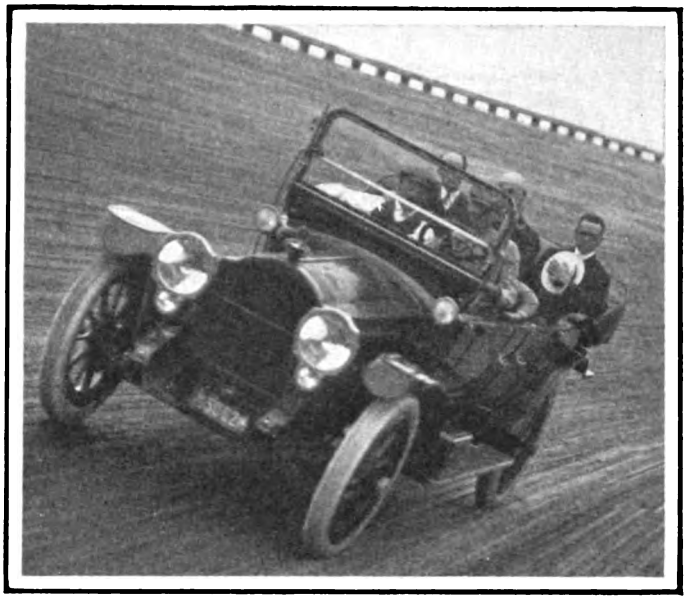
Next, Ralph De Palma, with one passenger, made a 10-mile run, with top down and windshield up, covering the distance in 8 min. and 15 sec., an average of 72.7 m.p.h. Although for a much shorter distance, this betters the record set by the Packard at last year's test by more than 2 m.p.h.

The last test of the day was a 10-mile run with Ralph De Palma driving. He carried six others in the car with him, had the top and windshield up and averaged 69.8 m.p.h. The lap time, as checked by officials on this run was:

Lap. No.	Time
1	1:43.8
2	1:44.2
3	1:43.8
4	1:43.3
5	1:43.3
Total	8:38.4

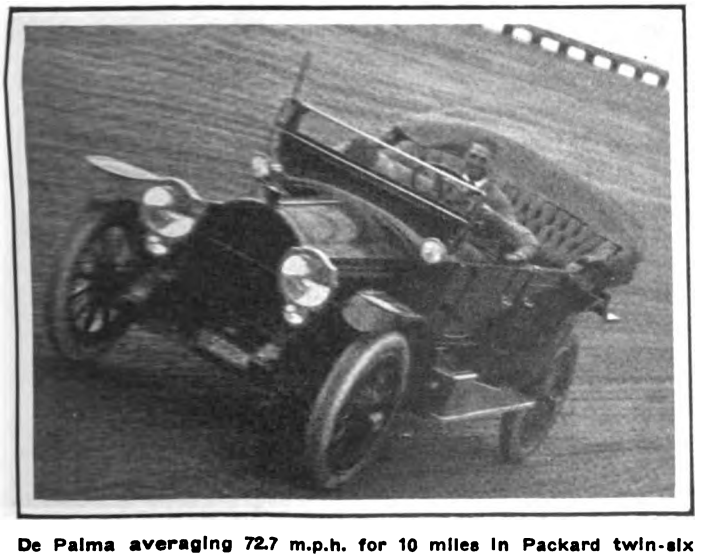
Average 69.8 m.p.h.

Both cars were in full touring trim in the trials. Wind resistance proved quite a factor with the top up and undoubtedly the lower average in the latter test as compared with the Indianapolis test last year is accounted for by the fact that in the previous trial in the Hoosier metropolis, the top was down.



Finish of 10-mile speed test. De Palma driving at 69.8 m.p.h.

One of the cars was shipped direct from the Packard factory at Detroit yesterday, and never had been given any tryout. The other was the twin-six President Joy of the Lincoln Highway Association drove to the Pacific Coast recently. Both carried regulation touring car equipment, including extra tires, and no changes were made in the cars. In other words they were exact duplicates of the cars of this type to be seen in daily use throughout the country.



De Palma averaging 72.7 m.p.h. for 10 miles in Packard twin-six on Chicago speedway

Owen Magnetic Makes Progress

Entz Transmission in Chassis Shows Great Improvement Over Original Design—A New Sort of Motoring

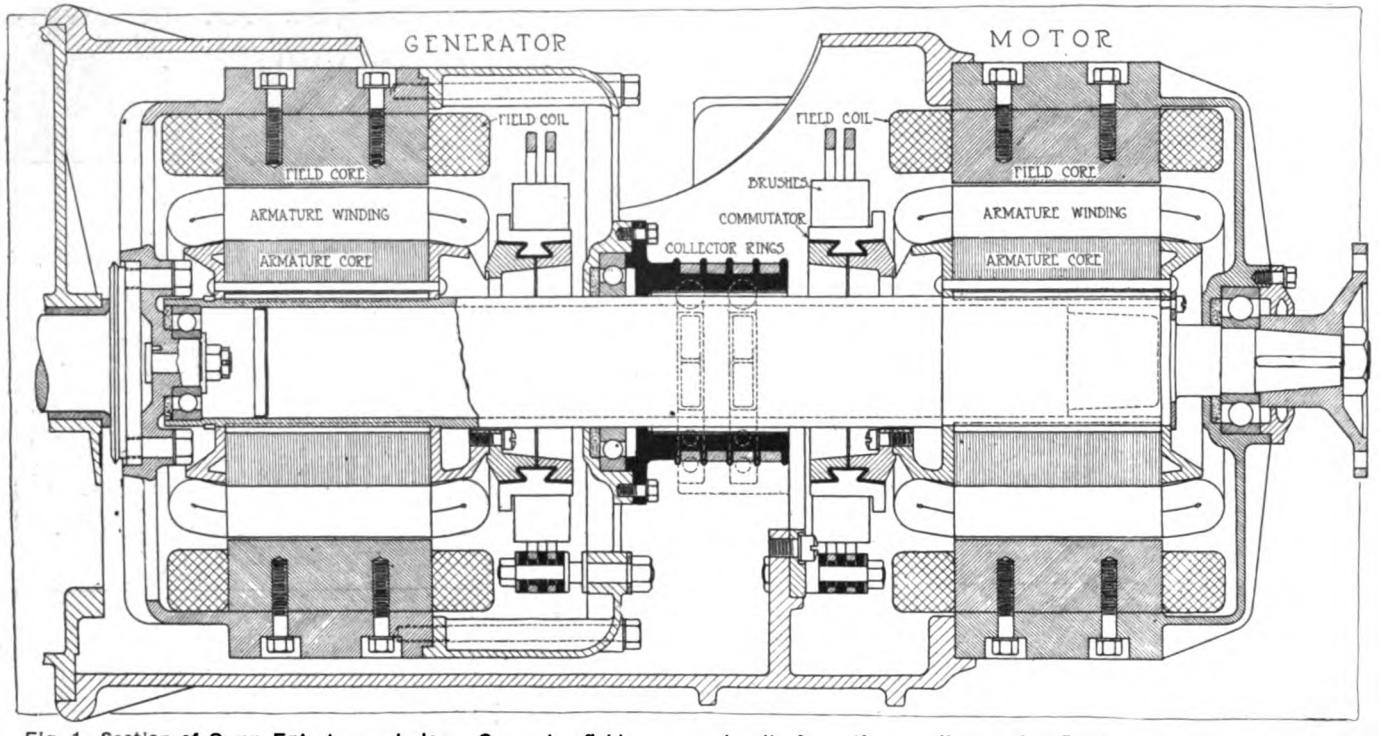

Fig. 1—Section of Owen-Entz transmission. Generator field cores and coils form the gasoline engine flywheel and the collector rings shown are for the purpose of connecting the field current of the generator to the various circuits. The brushes of the generator revolve with the field. The two armatures are identical and both are keyed to the hollow shaft which is attached to the propeller shaft and has no connection with the engine

IN the Owen magnetic transmission car there is never any positive gear connection between the motor and the rear road wheels.

Quite what this means is appreciated, once it is experienced, but to describe in words the effect, from the viewpoint of the ordinary passenger in the car is extremely difficult. If the reader has ever ridden in a wind wagon or a wheeled vehicle driven by an aeroplane motor and aeroplane propeller, he will have some idea of how the Owen car feels to ride in. Or if he has not this experience an idea may be obtained by imagining an immense rubber shaft which is twisted at one end by the motor and drives the axle by untwisting at the other. That is to say there is a perpetually soft cushion between the source of power and the wheel, it is impossible for shock of any sort to be carried from one to the other as the intermediary mechanism forms a sort of energy reservoir always prepared softly to absorb excess power or to give out again extra torque to the axle.

Perhaps it might be said that the magnetic transmission is to the chassis what the pneumatic tire is to the wheel. It does not add so much to the comfort of motoring as does the pneumatic tire compared with a steel tire, but the utter absence of all sense of hardness is very similar to that given by the pneumatic.

The Dual Control

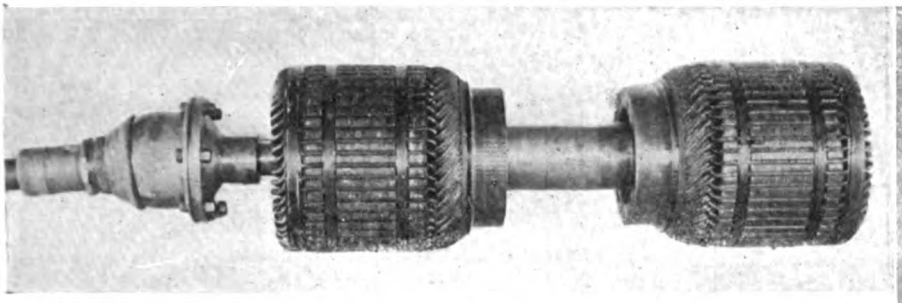
The car handles more as though it had only one speed. There is a throttle pedal which operates normally, and above the steering wheel is a lever very much like the usual throttle lever. If opening up on the accelerator pedal is not enough to meet the road conditions of traffic or gradient, then the lever is pushed along an inch or two, and the car gathers way just as though a second gas feed had been put into commission or a few more cylinders added to the motor.

An Ever Slipping Clutch

The principle of operation is really that of the clutch. The Entz transmission is an electro-magnetic clutch which is always slipping, sometimes a great deal, sometimes a very little; and the energy dissipated by the slip is caught, to be used up again later on. If a car had a clutch made of some material which could not be burnt nor worn out it would be possible to arrange a transmission by a purely mechanical device for tightening or loosening the grip of the clutch, but if this were done, the instant the clutch began to slip energy would begin to be thrown away in the form of heat. This could not be recovered, and also the more we wanted to use the slip so as to give the effect of a lowered gear ratio the greater the proportion of the power that would be wasted.

The magnetic transmission is a clutch that can be tightened magnetically, but the slip creates electricity instead of heat, and the electricity is used to drive the car. We take the high-speed energy from the motor and apply low-speed energy direct to the axle without any connection save a few stout wires.

Naturally enough, a thing so different from the ordinary creates fear in the mind of the prospective purchaser; he wonders what peculiar tricks it may have that he will not be able to understand, and the electrical part awes him with its bright commutator bars and big brushes. Perhaps the



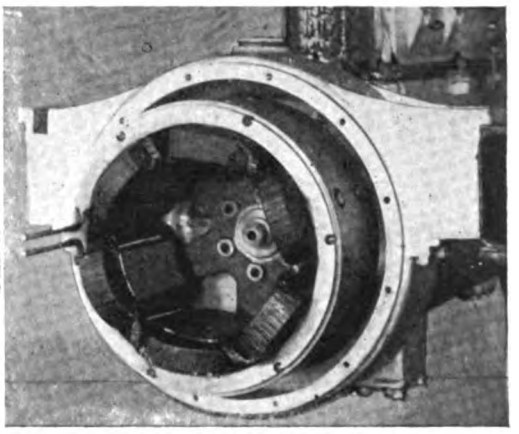


Fig. 2—Left—Armatures of motor and generator attached to propeller shaft
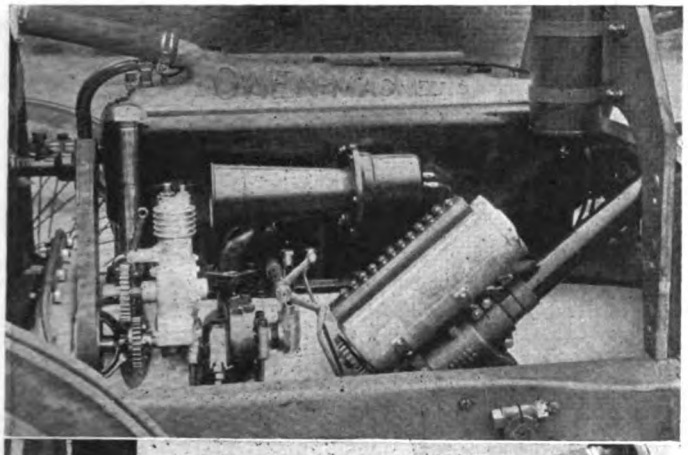
Fig. 3—Right—Field coils, etc., forming flywheel of gasoline motor

simplest way of tackling this point of view is to say that the essentials of the electrical transmission are units of electrical machinery that central station work of nearly two generations has proved good. Added to this is the extremely important point that the brushes and commutator bars which are the only parts of an electric generator that can possibly wear are hardly ever used anything like so hard as they would be in lighting service.

Like all other cars the Owen magnetic does most of its work on high gear and the difference in speed between the electrical moving parts is then only from 60 to 100 r.p.m., as compared with several hundreds of revolutions for a central station dynamo or several thousand for an automobile lighting generator. Obviously so slow a rubbing speed of brush on commutator as this can produce but very little wear indeed so the life of the parts ought to be very great.

Process of Driving

To start the car all there is to do is to pull the lever on the steering wheel into the starting position, which turns the motor over at a high speed, owing to the size and power of the electrical machines available. Then, without touching the accelerator pedal it is possible to go forward or backward by merely moving the lever on the steering wheel to and fro.



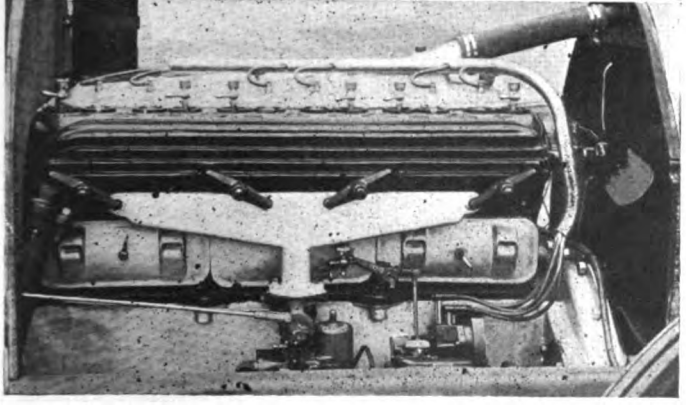


Fig. 4—Upper—Controller box at base of steering column, showing gear connection. This box contains all switches and resistance coils
Fig. 5—Lower—Buda motor in Owen Magnetic chassis

Flexibility Illustrated

One of the most curious effects is that the motor can be used to hold the car on a grade by letting it turn over at an idling speed and putting the lever in a position which allows the maximum slip in the transmission short of complete freedom. A favorite demonstration with the car in order to show the flexibility of the transmission is to drive the car to the middle of a ramp with fairly steep gradient, set the hand lever in a position where the motor can hold the weight of the car against gravity and then go slowly forward or backward by gently opening or closing the throttle. It is not suggested that this ability to use the motor to play with the car on a grade is of much utility, but it is a good way of showing how the transmission is the equivalent of a clutch that can be tightened or loosened by varying the magnetic grip.

Stages of Grip

Turning to the diagram, Fig. 1, the field magnets and coils of the *generator* form the flywheel of the engine. Neglecting the *motor* part of the transmission, the armature of the generator is on a shaft running free on a spigot ball bearing in the flywheel and attached at the other end to the drive shaft and so to the bevel pinion of the rear axle.

Thus the field of the generator runs always at engine speed while the armature of the generator runs always at propeller shaft speed.

The effect of running the engine and so spinning the field magnets of the generator is to induce currents in the armature which make a magetic attraction between the armature and the field. This is equivalent to tightening the fields upon the armature if we follow the clutch analogy, so the armature tries to turn with the field and will do so if the resistance to motion of the car as a whole is not too great. This means that part of the energy in the flywheel of the engine goes to the creation of electric currents in the armature coils, and part to the direct mechanical work of turning the armature and so driving the car.

Now this current that is created in the armature of the generator is taken to the second part of the transmission which is an electric motor. This is also shown in Fig. 1 and its field magnets are fixed stationary while the armature is keyed to the same shaft as the armature of the generator. Thus whatever else happens the two armatures are always running at the same speed and that speed is the speed of the propeller shaft.

Circuits One by One

On the foot of the steering column there is an aluminum case containing sundry resistance coils and a switch or two.

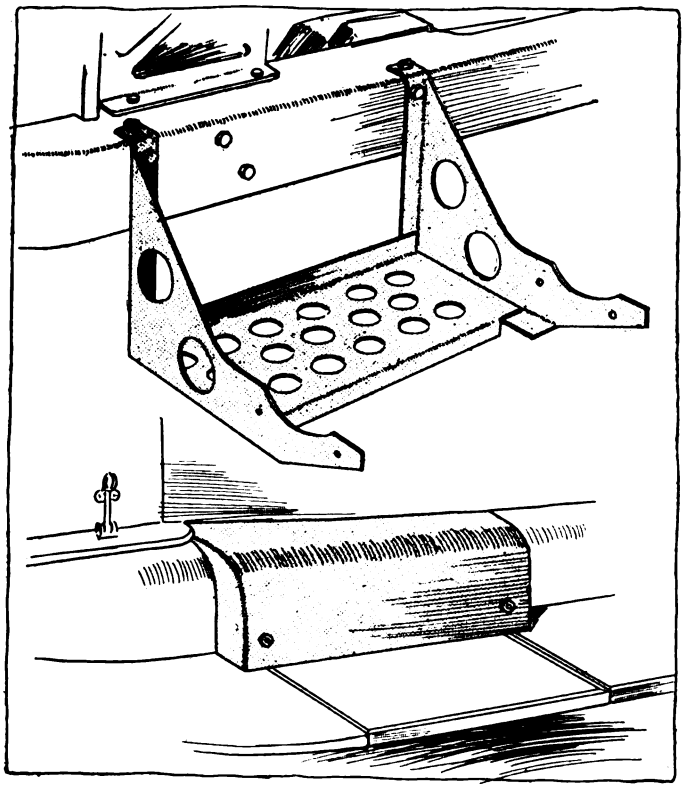

Fig. 6—Upper—Steel cradle attached to chassis side member for support of battery

Fig. 7—Lower—An instance of the neatness of the car. The battery cover on the running board. This is attached by two nuts and a portion of the board slides out if it is desired to remove the battery completely

The parts are of robust size and comprise the whole of the control. In the following the effect of moving the lever on the wheel is described in electrical terms and the description should be read with continuous reference to Fig. 1, remembering all the while that:

a—The generator field runs at engine speed.

b—The motor field is stationary.

c—Both armatures revolve together at drive shaft speed.

Neutral Position

All circuits are open and there is no current being generated or used. The battery is idle unless in use on the lamp circuit at night.

Cranking Position

Current from the battery is switched into the generator causing the latter to behave as a motor and spin the engine.

Charging Position

Small boosting charge taken from generator and put into battery, only used if battery is accidentally low.

First Car Motion

Generator field windings connected through resistance thus causes gentle excitation and prepares the generator for larger current demands.

Second Position Equals Lowest Gear

The generator field is short circuited so that maximum current is produced. This causes the field to grip the armature and also sends current from the generator to the motor part of transmission where it assists to drive car. Battery is totally out of use.

Third Position

Resistance is switched into the field coils of *motor*, so throwing a greater load on the generator which is equivalent to tightening the magnetic grip on the armature.

Fourth Position

It is similar to last only more resistance is put into the motor field. Successive positions act in the same way till we come to the seventh and last.

High-Gear Position

As in the first-speed position the generator field is shorted, but instead of current being sent to the motor none is switched into any outside circuit whatever. This gives the greatest possible grip because all the current generated is used to attract the armature and drag it around. This high-gear position is paradoxial to some extent because the effect of the grip caused by the current is to reduce the current. That this is so can be seen when it is remembered that the amount of current is proportional to the relative speeds of the generator fields and the generator armature. When these are, say, 1060 and 1000 r.p.m., the relative motion is only 60 r.p.m. and the current generated very small, but just enough to maintain the grip. If we now strike a road resistance like a grade the relative motion increases, the current increases and the grip increases so the clutch tightens itself up automatically to suit the road conditions.

In the high-gear position we have explained that no current is sent to the motor; on the contrary, a special small shunt winding on the motor field is switched into circuit and thenceforward the motor delivers a charging current to the battery.

Electric Brake

An accidental feature of the transmission is to provide an extremely powerful electric brake which automatically releases as the car slows down. It cannot be used for stopping the car altogether because its power depends upon motion of the vehicle, but it is very effective when the car is traveling fast. If the lever be put into the neutral position when the car is running the heavy current induced by the motion of the car in the series winding of the electric motor is turned into the resistance coil employed in the charging position which is used for boosting the battery, as explained above. On a steep grade this electric brake will keep

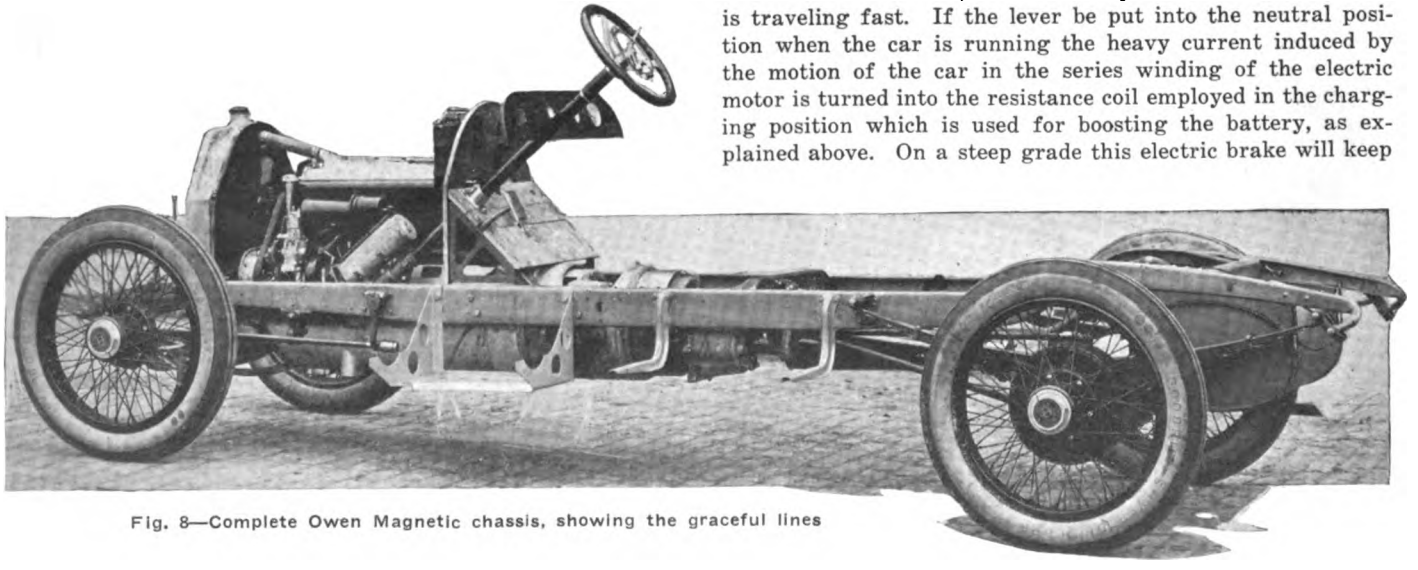

Fig. 8—Complete Owen Magnetic chassis, showing the graceful lines

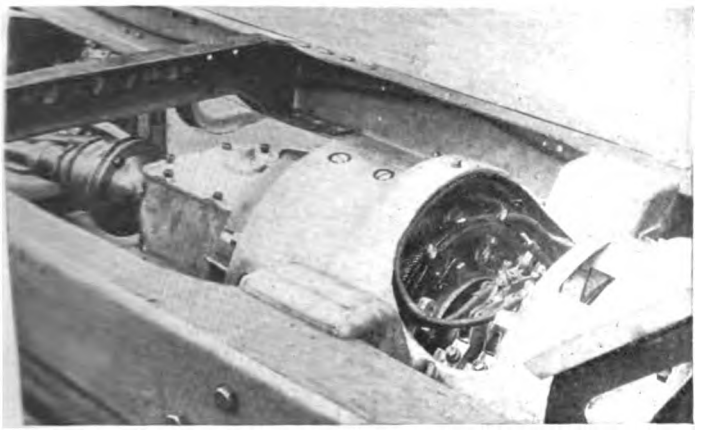

Fig. 9—Complete transmission in place in the chassis, showing accessibility of brush gear

down the speed of the car to 15 or 20 miles an hour, and as it is very useful. Of course it has no wearing parts.

So much for the electrical system; the description is sufficient for anyone who knows a little electrical science and no amount of description will make the detail operation clear to a man who has no electrical knowledge whatever.

Made from Good Components

Desiring to give the transmission the very best opportunity to exhibit its advantages in the hands of users accustomed to the best sorts of automobiles, the Owen company selected for the chassis the parts which it thought would be reliable. For the motor a six-cylinder Buda is used, tested twice by its makers and delivered under a contract that provides for a class of finish usually reserved for exhibitions, and a final inspection after all ordinary inspecting processes are over. Magneto ignition is used, not because the electric energy of the battery could not be employed, but because the magneto makes the motor a separate unit complete in itself.

The rear axle is made by the American Ball Bearing Co., with spiral-bevel drive and very large brakes of the expanding type, totally enclosed. Steering gear and front axle are similarly good and every detail fitting is of the very best quality. In the design of the springs the engineers of the Perfection Spring Co. were given a free hand and the result is remarkably easy suspension with semi-elliptics all around. In designing the radiator the honeycomb, pointed type used for years by Mercedes and Austro-Daimler has been kept in mind, and the bodies are costly hand-made jobs with lines that are in keeping with the chassis.

The engine and the aluminum-housed transmission together make a unit power plant, and connection to the rear axle is through an open-type propeller shaft with two universals. On some of the cars which are intended for long-distance touring a two-speed gear transmission has been added to the rear axle so that the whole electrical range of speeds may be available with either a high or a low axle ratio. Normally a bevel ratio of about 3.5 to 1 suffices and the Pennsylvania mountain roads have been tackled on this gear.

Since the transmission was described in THE AUTOMOBILE a little more than a year ago it has not been changed in principle, but the car has been changed a good deal. Instead of being an experimental vehicle with the noticeable crudities of experimental jobs, it is a handsome car with a well-designed and proportioned chassis.

Thus described the chassis sounds simple enough, as it certainly is. There is no mystery about the action of the transmission whatever. What cannot be put into words is the really remarkable difference between driving a car with this transmission and an ordinary car. One most curious effect is that if the foot is taken off the accelerator pedal the effect is equivalent to releasing the clutch of an ordinary car. The motor is totally disconnected as soon as the magnetic grip lets go and this it practically does as soon as it gets down to idling speed. Downhill, then, the car coasts freely and in pulling up on the level the throttle can be shut much further from the place where it is desired to stop, since there is no frictional resistance offered by the motor as it slows to idling speed.

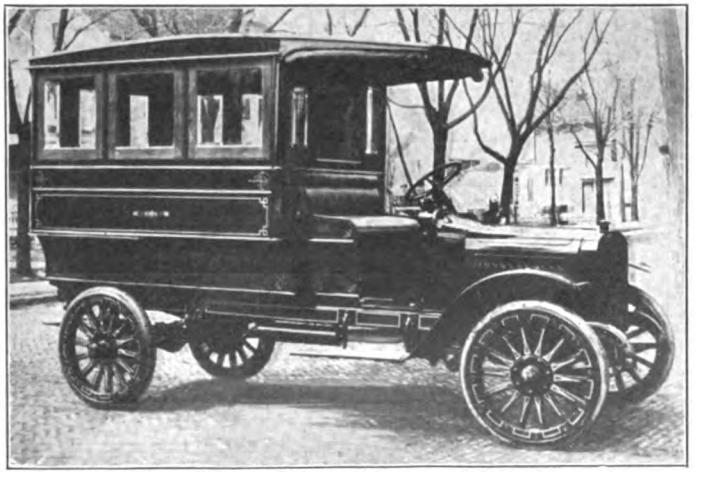
While all ordinary hills can be taken without touching the control, the wide range of speeds allows a very rapid acceleration up hill if starting on the grade because the engine can be allowed to run up to 1000 revolutions or so and then the control slowly pushed forward. As step by step it passes the engine speed holds more or less constant at its power peak position and the car gathers speed.

To handle this car is an experience that would be enjoyed immensely by any driver of experience because it provides a really new sensation. Though easy to handle there are many little things which can be learned and which help to get the very best out of the car and there is a great fascination in controlling with a touch of the finger instead of with combined action of hand, foot and eye.

Beck Jitney Bus Has Steel Body

A vehicle which is suitable for either hotel bus or jitney work with a body having a passenger capacity of ten or twelve has been brought out by Beck & Son, of Cedar Rapids, Iowa. It has a rated capacity of 2,000 pounds and is an assembled design throughout with a special body built of steel. As shown in the accompanying illustration, this is a drop-window design with a rear step. It is upholstered throughout in leather and is weather-proof.

The power plant is a Continental, 3.5 by 5 design with the four cylinders cast in a single block. Other specifications of the motor include a three-bearing crankshaft, splash lubricating system and thermo-syphon cooling. The power is delivered through a twelve-plate disk clutch to a three-speed gearset. Throughout, the drive is standard, being taken through two universal joints to an internal gear rear axle having a ratio of 6.5 to 1. The wheelbase is 124 inches, the tread standard and the tires are solid 35 by 3 front and 35 by 3.5 rear. Pneumatics 35 by 5 will be furnished at an extra cost of $50. The car is fully equipped for electric lighting having a 100-ampere hour storage battery.



Combination jitney and hotel bus brought out by Beck & Sons, Cedar Rapids, Iowa. It has a capacity of 2,000 lbs.

The Engineers' Forum

American-Built Motors of Recent Design Compare Favorably with European Products—Both Develop Over 12 Horsepower Per Liter Displacement

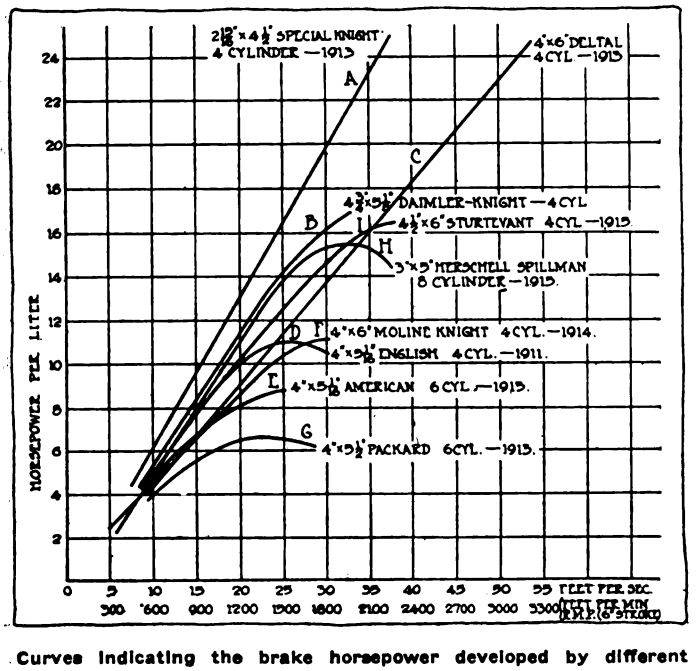
By Chester S. Ricker, M. E.

INDIANAPOLIS, Ind.—Editor THE AUTOMOBILE:—The first article by S. Gerster on Europe's High-Efficiency Motor in THE AUTOMOBILE for April 15 is exceedingly interesting as it brings up some very pertinent questions in regard to motor speeds. Mr. Gerster gives racing motors an average piston speed of 59 to 65 feet per second and touring car motors 46 to 52 feet per second in the paragraphs which apply to this factor in motor efficiency.

It is very interesting to compare some curves which were published under Mr. Charles Y. Knight's name in THE AUTOMOBILE for December 4, 1913, with curves of some later motors, such as have been brought out during the past year. One of these motors is an eight, the other a four-cylinder. It is particularly interesting to make these comparisons after reading Mr. Gerster's article because it gives one a concrete answer to the question, "How near do American motors approach the best European practice?"

Power Per Liter Displacement

The only way that the writer knows by which motors of varying sizes and strokes may be directly compared is to plot curves between piston speed and horsepower per liter. While it would seem more logical in this country to use cubic inches per horsepower as one of the units, it is more convenient to employ the liter displacement unit in order to make direct comparisons with European figures. In Mr. Knight's power curves r.p.m., instead of piston speed, is made the abscissae, but that is hardly fair to either long or short stroke motors, so his curves, A, B, C, D, E in the accompanying plot have been corrected to read feet per second instead of r.p.m. Otherwise no changes have been made in his curves and in addition curves, F, G, H, I have been added.



Curves indicating the brake horsepower developed by different motors under test

Official Tests of Eight and Four

Curves F and G are particularly interesting as they are the official test results obtained from the Automobile Club of America tests on the two motors in question. The curves, H and I are equally interesting because they are representative of two entirely new developments in commercial motor design. The first one is that of the new Herschell-Spillman eight-cylinder V motor, while the second curve is that of a four cylinder T-head motor with four valves per cylinder. The latter motor has been in hard service for over a year in quite a number of motor boats, one in particular being the U. S. Navy record-breaking Hydroplane. In this service it runs normally at 75 per cent. of its maximum power, yet at that speed it delivers 12.3 horsepower per liter of displacement, which is considered very high.

Consideration of the Curves

Curve A. This curve was made by a small special Silent Knight motor having 126 cubic inches displacement, 2.016 liters and developing 50 horsepower at 3,000 r.p.m. The bore and stroke of the motor were 75 by 114 millimeters. Its maximum piston speed was, therefore, 37.5 feet per second. It also raises the question in the writer's mind as to how much more power this motor would have developed had it been carried up to 50 or 60 feet per second, as Mr. Gerster states can be done in racing practice. Suffice it to say, that the Knight motor performance has the characteristics towards which all other motor builders are striving. But this curve represents a motor which is not commercial so we must turn to one which is.

Curve B. This is much more nearly a standard of Knight practice in commercial motors, but Mr. Knight states that the maximum efficiency of this motor, 16.75 horsepower per liter, was obtained at 2,200 r.p.m. and that two carbureters were used, two Zenith carbureters being the only non-standard feature of the motor.

Eight Develops 70 H.P. at 2,380 R.P.M.

Curve H. The third highest curve is that of the Herschell-Spillman eight-cylinder motor. This motor developed a maximum horsepower of 70 at 2,380 r.p.m. at which point its efficiency of performance was 15.5 horsepower per liter of displacement. The cylinders have 3-inch bore and 5-inch stroke, giving a displacement of 282.4 cubic inches or 4.518 liters. The test was made with the motor equipped with

Westinghouse ignition and Zenith eight-cylinder type of carbureter. The latter was fitted with No. 21 Venturi tube, No. 120 jet, No. 115 compensator and No. 50 well. It is very interesting to note how closely this curve parallels that of the standard Knight curve, B. It shows that this motor runs just a little faster in order to accomplish the same results. If the valves were only a bit larger this motor would probably duplicate the Knight performance.

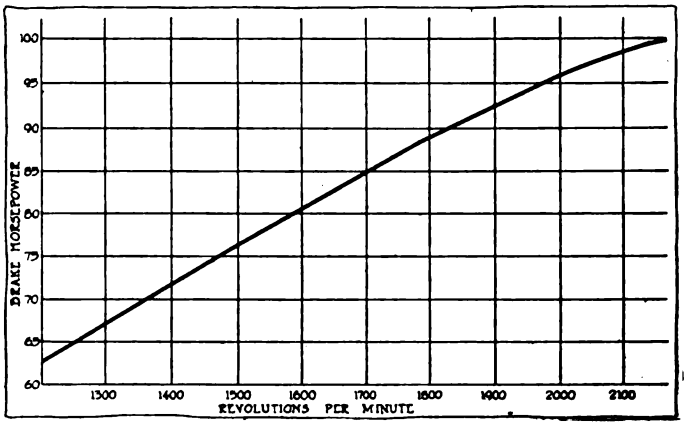
Curve I. The Sturtevant motor seems to be a continuation of the Curve D which was taken from some anonymous English motor. It does not show such a rapid increase in efficiency as the eight but reaches a bit higher output, the best performance of this motor being reached at 2,150 r.p.m. when it develops 100.5 horsepower or 16.4 horsepower per liter. But this motor is designed to run normally at an output of 12.5 horsepower per liter and does it. The next best efficiency for long running is found in the Moline-Knight Curve F, which has a maximum output of 11.1 horsepower per liter, at 28.6 feet per second. During the 300-hour test at the Automobile Club of America it developed only 7.94 horsepower per liter when running at an average speed of 18.6 feet per second for the whole test.

Curves D, E, F, and G are used merely for comparison.

Some Details of Sturtevant Motor

The Sturtevant motor has a T-head cylinder like that shown in Fig. 6, of Mr. Gerster's article only the valves have vertical stems instead of inclined ones. The bore and stroke are 4.5 by 6 inches, respectively, the displacement being 381.6 cubic inches, or 6.105 liters. At 1,475 r.p.m. or 24.6 feet per second piston speed, this motor develops 75 horsepower, or 12.3 horsepower per liter. At 2,150 r.p.m. or 35.9 feet per second it develops 100.5 horsepower or 16.4 horsepower per liter.

The motor is not freakish in construction and surprisingly light for a marine engine. It weighs only 650 pounds, including the reversing gear mechanism, clutch and elevated starting crank. The valve diameter, clear, port opening, is 1 13-16 inches. All the valves have a 7-16-inch lift and a 45-degree seat. The valve timing is not unusual except that



Brake horsepower curve of the four-cylinder Sturtevant marine motor model E-4

the inlet and exhaust valves are overlapped. This, however, has been practiced on T-head motors for a long time. The exhaust valves open 45 degrees ahead of bottom center and close 10 degrees after top center. The inlet valves open on top center, thus overlapping the exhaust 10 degrees, and close 30 degrees past bottom center. The compression ratio is 4.5 to 1. All of these motors are equipped with a standard 2-inch Zenith carbureter, this size having been found to give the maximum performance. The reciprocating parts are especially light, considering that the pistons have three rings and are made of cast iron. The piston pins turn in the piston bosses which are bushed with bronze. Still the pistons, with rings and piston pin, weigh 1,150 grams or 2.54 pounds and the connecting-rods weigh 1,180 grams or 2.6 pounds. The total weight of reciprocating parts, therefore, is only 3.84 pounds. These tests were made with Bosch ZR magneto and only one set of spark plugs over the intake valves. It is quite possible that this motor would have developed more power if two spark plugs had been used.

Conclusions

From the above, it seems that we are building motors in this country that show up very well with European commercial products, although both of these motors only have a maximum speed of about 37.5 feet per second and a normal running speed of about 25 feet per second. Both of these motors can develop better than 12 horsepower per liter displacement, which seems from this data to be the average towards which we ought to strive—this power output to be obtained at not over 25 feet per second piston speed. It will be noted that the eight-cylinder motor develops nearly 14 horsepower per liter at this speed.—CHESTER S. RICKER, M. E.

A Jeffery quad hauling a Krupp gun belonging to the Belgian army through northern France

War Trucks and Tractors Well Tested

Organization Excellent—Guns on Four-Wheel Drive Chassis

By W. F. Bradley,
European Representative of THE AUTOMOBILE.

PARIS, June 21—After several months spent in France and Belgium in the respective interests of the Jeffery and the Knox companies, Messrs. H. C. Hill and H. F. Blanchard will sail from Bordeaux for New York next Saturday. Mr. Blanchard has demonstrated the Knox tractor to the French army authorities, and after tests on gradients officially certified to have 12, 16 and 19.7 per cent, has convinced the authorities of the value of his vehicle and has been given the desired contract. Mr. Hill is leaving behind in France about 2,000 Jeffery quads and trucks and fifty Jeffery quads in Belgium. In addition, England has 100 and Russia 400 quads.

French Army Trucks Well Manned

"Before coming over here," said Mr. Blanchard to THE AUTOMOBILE representative, "I was filled with stories about disorganization in the French army. According to these reports all the men who knew anything about automobiles had been sent into the trenches and green men were being broken in to handle trucks. It was stated that everywhere there was a square peg in a round hole. Well, I have seen something of French military matters, and I want to say that they have some organization. Everywhere I have been the officers and men have been leading engineers from good factories such as the Delaunay-Belleville, Panhard, De Dion Bouton, Delage and Peugeot, who know everything there is to be known about an automobile. Up at Havre the man who receives and tests American trucks is Adjutant Lemale, a clever Delaunay-Belleville engineer and inventor of a wonderful gasoline turbine used in French torpedoes. His assistant was attached to the Darracq factory. The chief French buyer is Lieutenant Lumet, who holds the post of chief engineer at the Automobile Club of France laboratory."

Tested in Ditches and Over Hills

Mr. Blanchard is enthusiastic about the way in which the French organize their convoys and test men and trucks. The American trucks come from Havre to Versailles in convoys of forty. In Versailles they are individually examined and fitted out, two drivers are put on each truck or tractor and they are sent where required at the front in convoys of twenty. Each convoy is in charge of a lieutenant on a touring car, and one of the trucks is equipped as a repair shop, and another carries the cooking stove for the men. Mr. Blanchard says that he had the good luck to be present at the final test of a dozen convoys of all-drive tractors, comprising Jeffery quads, Panhard, Renault and Latil four-wheel drivers. They were taken over the hilliest and roughest country around Paris. The Jefferys had to go through a ditch so deep that when the nose of the first machine was down the starting crank was broken off. The crank was fastened up and each machine went through the ditch with a clearance at the front when the rear was elevated of not more than a couple of inches. This test was for the benefit of drivers as well as machines, and no green man could possibly get through it without detection.

75-Mm. Guns on Jeffery Quads

The French government has formed twelve batteries of 75 mm. guns on Jeffery quads. The gun, which weighs 2 tons, has a special mounting on the truck platform, and when it is about to be fired the chassis is raised by means of special jacks so as to take all the load off the springs. The system is so perfect that if a piece of note paper is laid on the top of the supplementary coil springs it will not be shaken off when the gun is fired. The gun kicks back against a special hydraulic brake, the nature of which is a secret, and returns to its original position without varying a thousandth of an inch. There are four guns in each battery, or forty-eight guns mounted in this way. In addition, each gun-bearing automobile is attended by a second Jeffery quad carrying ammunition.

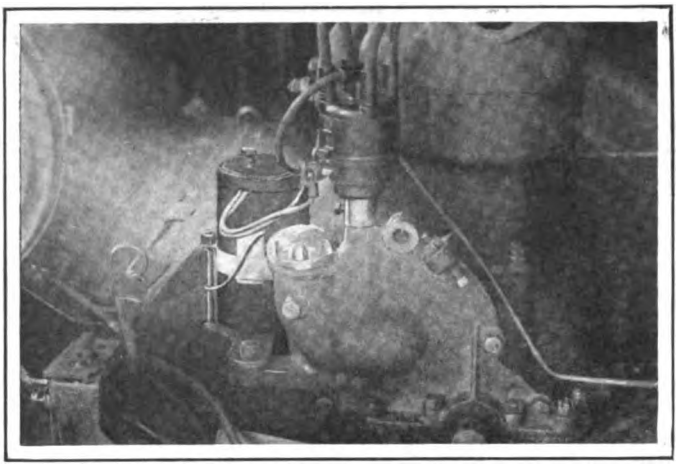
In addition to France, Mr. Hill has transacted business with the Belgian government. Practical tests, in which the Jeffery quad had to haul a heavy Krupp gun, were made in rough

Connecticut Battery Ignition for Fords

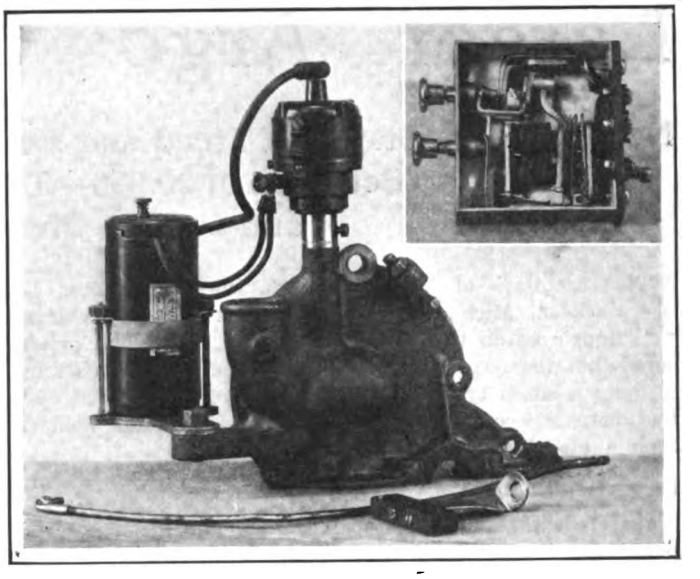
System Mounted on Interchangeable Timing Gear Cover Plate

MERIDEN, CONN., July 10—The Connecticut Telephone & Electric Co., this city, has brought out an edition of the Connecticut ignition system especially adapted to Ford cars. The complete outfit, including wiring and everything except the battery, sells for $28.50 and one of the features of its construction is that it can be quickly installed upon any Ford car. As shown in the accompanying illustration, the plate which fits over the timing gears of the Ford at the upper front portion of the crankcase is replaced by another which is interchangeable with it but which contains the vertical shaft for the timer distributer together with the bevel gear drive necessary for operating it. On a bracket, integral with this same plate, the single unit coil, which is a high-tension, non-vibrating design, is also mounted and connected to the timer distributer by short wires.

The remaining unit is a switch which includes the Connecticut feature of disconnecting the battery, should the switch be left in the on position with the motor not running. The automatic release is effected by a small rheostat which becomes heated from the continuous current passing through it from the battery and bends over, making contact with a small buzzer coil arrangement which in turn kicks the switch out of contact. It is thus impossible to run down the battery by accidentally leaving the switch turned on.



The system as it appears mounted on a Ford motor



Units of Connecticut Ford system. Insert—Flush dash switch

Switch Flush with Dash

Another feature of the switch is that it sets flush with the dash, having only the control buttons on their metal plate visible on the driver's side. The coil being mounted on the new timing gear cover plate which replaces the old one does away with an awkward mounting on the dash of this instrument, thereby permitting a neat layout which can be easily installed with the tools in the ordinary kit.

The Connecticut system operates on the open circuit scheme, the interrupter being so constructed that the primary circuit of the coil is completely saturated before the breaking point is reached in order to produce a spark of maximum intensity upon the interruption of the circuit.

It is claimed that with this system, both electrical and mechanical lag have been eliminated throughout the entire range of motor speed. The breaker mechanism consists of an arm carrying one contact piece, a stationary block carrying the other, an insulated roller carried upon the arm and a cam mounted upon the driving shaft. On the driving cam there are four high spots for the Ford outfit, each of them being 90 deg. from the next. This allows a period for maximum saturation.

Synchronism of ignition, or that quality which allows the spark to occur at the same relative part of the stroke, is obtained by the elimination of the electrical lag due to the intensity of the induced current. In other words, for all practical purposes, the spark occurs at the same position as regards piston travel regardless of the speed of the engine.

The wiring of the system is very simple and by following the directions with the outfit, even an amateur motorist will have no trouble in installing the outfit. The current is taken from the coil lead to the central point of the distributer mechanism and from there carried by means of a brush, to the high-tension terminals from where the current is taken on the high-tension lead directly to the spark plug.

A. J. Picard & Co., New York City, are the exclusive distributors for the new system.

---

country between Calais and Dunkirk. These guns were supplied by Krupp to the Belgian army some time before the war. They were found to be most efficient weapons, but when the ammunition which had been furnished by the German firm was exhausted no more was available. This difficulty has been overcome by making special shells for these guns in the French factories. The Krupp gun was dragged into difficult positions by five teams of four horses each and had to be got out by one tractor. This was accomplished in every case, and the Belgian army has now secured fifty quads, all of which are used for hauling guns.

In addition to the quads, Jeffery has delivered 1,000 ¾-ton trucks to the French government for ambulance work. These chassis have pneumatic tires, twins at the rear and singles at the front, and bodies are fitted in France to meet various requirements in this field of military work.

Larger Argo Chassis for 1916

New Car Has Standard Tread and 2¾ by 4½ Four-Cylinder Motor—Production Schedule of 20,000—To Sell for $385 as Roadster and $435 as Five-Passenger Touring

IN these days of low-priced cars, the Argo Motor Co., Jackson, Mich., still is conspicuous for the moderate figure set on the cars of its make. It will be remembered that the Argo company was formed several years ago to build a small type of roadster with 44-in. tread at $295, Benjamin Briscoe and his associates realizing the field for such a moderate-priced machine.

Large Output Planned

Just recently, however, the Argo company brought out a new chassis with standard tread which incorporates a number of improvements and differences over the first model. The new roadster is a very nicely designed car of the lighter type and is built to sell at $385, while on the same chassis, a neat five-passenger body is fitted, the price in this form being $435. Plans are well under way, it is said, for a large output of these two cars for the coming season, some 20,000 of them being on the schedule. This at once gives one good reason why the price can be made so low, for the size of output is one of the biggest price-controlling factors.

The car throughout has been designed for quickness of assembly and simplicity of construction, so as to bring the per car cost reduction to what the Argo concern believes to be very near the minimum.

The specifications include a 2¾ by 4½-in. motor, wheelbase of 96 in., cone clutch, Atwater Kent ignition, left steering, semi-floating rear axle fitted with the Bailey differential, elliptic spring suspension, two-speed gearset and 28 by 3 tires.

Lightness a Leading Feature

In the general makeup of the Argo, lightness of weight has been a paramount consideration, and just how well the designers have succeeded in this is brought out by the fact that the roadster tips the scale at about 1000 lb., with the touring car weighing only 200 lb. more.

The motor is a conventionally-designed four, with the cylinders cast in block, and with the valves all on the right and inclosed by a plate. The cylinder block is separate from the crankcase to which it bolts in the regular way. The case is of aluminum and of the barrel shape with a large plate at the bottom for getting at the crankshaft bearings. To disassemble the crankshaft a large plate at the rear end of the case admits of its being pulled out through this end.

This construction of the crankcase makes a rigid engine, and the arrangement has been employed on a number of other engines with good results. The motor really develops a very creditable amount of power for its size. On brake test it shows about 17.5 hp. at normal operative speed, whereas the S. A. E. formula rates it at 12.1 hp.

Three-Point Motor Suspension

The suspension of the engine is at three points, due to the resting of the front center on a cross-member and the use of a bar of steel tubing at the rear, this taking the place of the ordinarily-used integral aluminum crankcase arms. Such a means of support makes a strong and light design without taking up a great deal of room.

Standard practice is adhered to throughout the working parts of the engine. The crankcase is a two-bearing type, and from it the camshaft is driven by gear, with the drive for the fan pulley and distributer by another gear in connection with this cam gear. These gears are all very neatly housed, and they are made readily accessible by conveniently-placed plates.

The distributer shaft is on the left and drives the vertically-mounted Atwater Kent instrument by bevel-gear connection. Cooling is effected by thermo-syphon, with large

New Argo Transmission Features

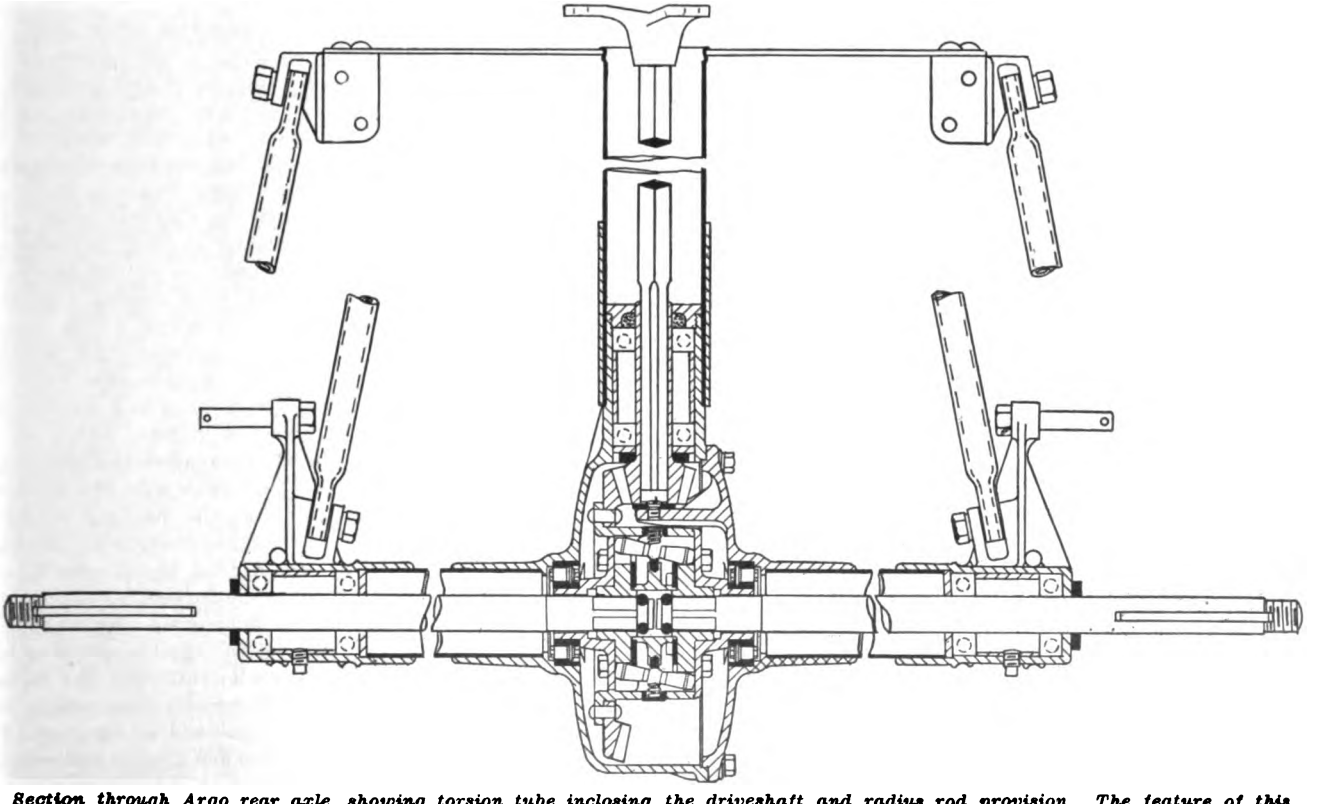
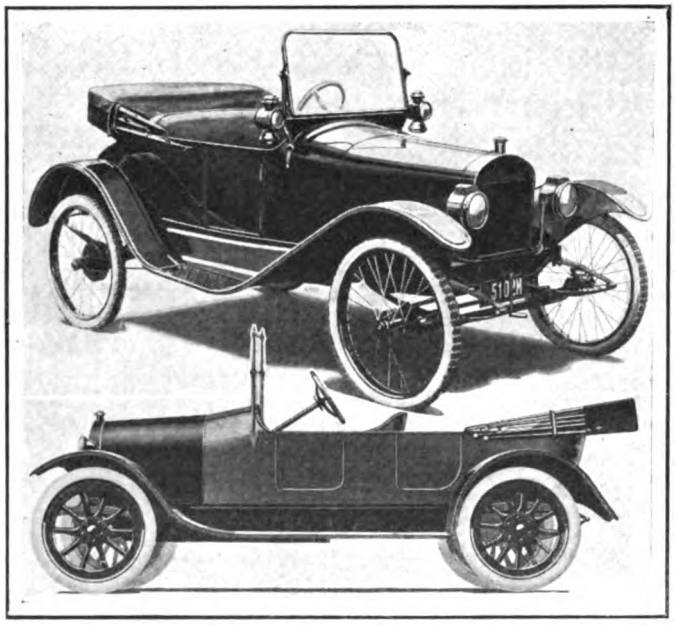
Right—Mounting of gearbox G and details of combined universal joint and transmission brake A placed between the clutch and the gearbox. As indicated, this brake is operated by the emergency brake lever, giving a very direct and powerful application



Section through Argo rear axle, showing torsion tube inclosing the driveshaft and radius rod provision. The feature of this axle is that it employs the Bailey gearless differential comprising pawls, driving sectors and ratchets to secure a positive drive while at the same time giving the necessary differential action between the two wheels



Above—New Argo roadster selling for $385. Lower—Five-passenger touring car listing at $435

water outlet extending practically across the top of the cylinder block. Adjustment for the belt-driven cooling fan is made in the bracket which supports it. This may be swung toward or away from the driving pulley to vary the center distance.

Splash oiling is used. There is a connecting-rod trough under each cylinder, and the oil is thrown by the rod ends. The reservoir which keeps the troughs supplied at a constant level is an integral part of the left side of the crankcase, its location making it very easy to put in the oil—a point which is so often overlooked.

In the chassis design there is a liberal use of chrome-vanadium steel, not only in the driving members, but other parts taking strain. The drive from the engine is taken through an internal cone clutch, the female portion being attached to the flywheel by cap screws. The cone is composition faced, and the thrust is taken by two Gurney bearings.

Back of the clutch there is a universal joint of special construction. It is really a transmission brake and universal all in one. The outer part of the joint takes the form of a drum, and a band is fitted around it. Operation of the emergency brake lever contracts this band, thus braking the car through the drive. The band is supported on a bracket which is attached to the side member of the frame.

Back of this two-fold unit the two-speed gearbox is located. It is hung from a rather wide frame cross-member by four bolts. Back of this the driveshaft is inclosed within a torsion tube, and there are radius rods running back to the ends of the axle tubes.

Bailey Gearless Differential

Instead of using the conventional bevel gear differential in the rear axle, the Bailey gearless type is fitted. This construction makes use of pawls, driving sectors and ratchets to form a positive driving connection between the driveshaft and the axle shafts, at the same time allowing for the necessary differential action between the two wheels. The Bailey differential has been described before, and is more or less familiar to the public. There are two ratchets, one attached to each axle shaft, and these are free of the driving sectors which surround them, and which are both fixed to the bevel ring gear. To make a driving connection between these sectors and the axle ratchets, pawls are used, these engaging teeth in the ratchets and also being directly in contact with the contact faces of the driving sectors.

This drives both wheels forward positively. When either of the driven ratchets revolves faster than its driving sector, due to turning a corner, the ratchet is shaped to push the end of the pawl out of its tooth, thus allowing the ratchet to have a free movement forward. To drive backwards, the sector moves in the reverse direction and pushes the end of the pawl out of the ratchet tooth, this throwing the opposite end of the pawl down into the tooth of the opposite ratchet.

Brake and Clutch on Same Pedal

The service brake system is very simply worked out by attaching the brake to the same pedal that works the clutch, bringing the brakes into play after the pedal has disengaged the clutch. The equalizer is up forward at the pedal, and rods run outside of the frame back to a unique mounting on the front end of the rear springs. The front hinge of the spring is used therefore as a mounting of the brake rod in addition to its function in the spring. From here a shorter rod goes back to the contracting brake band.

There is a surprising amount of room in the touring body, considering the chassis length. Of pressed steel construction throughout, this body gives room for three in the back seat with sufficient leg length.

In either the touring car or roadster, the front seat is adjustable for height and leg room. It can be moved forward or back 3 in., and the same amount up and down.

For $60 additional, the cars are fitted with a single-unit Disco electric starting and lighting system. This attaches to the right side of the engine and is connected to the crankshaft just forward of the flywheel by a silent chain.

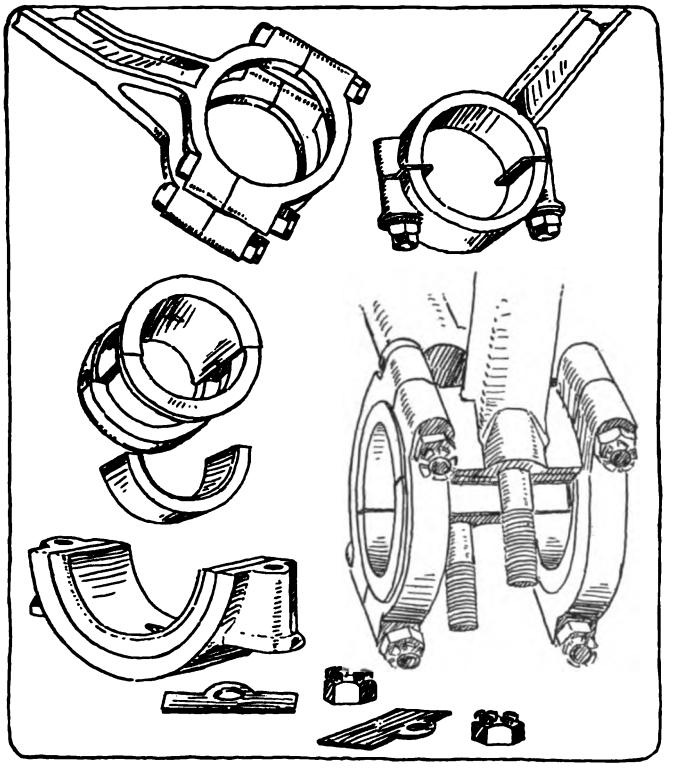
The standard equipment includes top and windshield, top cover, tools, tire pump, horn, gas headlights, and oil side and rear lamps.

Westinghouse Has Two Starting Motors

The Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., will make two types of starter for next season. One has a Bendix type of drive called the automatic screw shift. In this the pinion is drawn into mesh by a quick-pitch thread on the starter shaft, the pinion being connected to the shaft through the medium of a spring. This spring serves to allow the pinion to turn relatively to the armature shaft of the motor so, if the pinion teeth should happen to meet the ends of the flywheel teeth, the spring simply twists a little and lets the pinion slip into mesh with the flywheel gear. The spring at all times makes an elastic cushion between the pinion and the flywheel, so that there is no tendency for the pinion to slip partly out of mesh when coming over each successive compression stage, while cranking a big four.

The other form of motor uses a magnetic shift and the teeth of the pinion and flywheel are in this case cut to a slight angle. They are helical teeth of small inclination. Switching on the current energizes a magnet which draws the pinion along splines on the shaft, against the tension of the release spring. This pulls it into mesh with the flywheel, and the current flowing all the time the starting motor is working is sufficient to keep the magnet energized. As soon as the engine fires the motor speed runs up, of course, and this has the effect of cutting down the current flowing in the starter circuit. Reducing the current causes the magnet to fall off in strength so that the release spring operates and disengages the pinion. This magnetic shift has the advantage that it requires only a small switch. Generators will be made having the ignition unit combined or separate, but the voltage controller and the cut-out are usually mounted in a separate case on the dash. The form of regulation adopted is the vibrator which gives constant voltage direct and not indirectly as in constant current types of generator.

Watson V-Rod Provides Adjustment



Disassembled perspective views of Watson connecting-rod

A CONNECTING-ROD for V motors has been brought out by John W. Watson, president of the American Bronze Co., Berwyn, Pa., which is designed to have the combined advantages of great bearing area and easy adjustability. In other words, this connecting-rod is intended to provide practically the full crankpin bearing area for each of the two rods, and at the same time have the feature of adjustability for any worn part without in any way altering the adjustment of any other part.

Easy Adjustment for Wear

With the Watson type of rod, the repairman can, by dropping the lower half of the crankcase, take up the wear on the crankpin bearings in exactly the same manner as he can with the conventional vertical motor. The cap is removed from the rod and by removing shims, the proper fit is given and the cap then bolted back into place. By the construction of the rod, arrangements are so made that either the forked portion, or that part between the arms of the fork, can be adjusted without disturbing any other part.

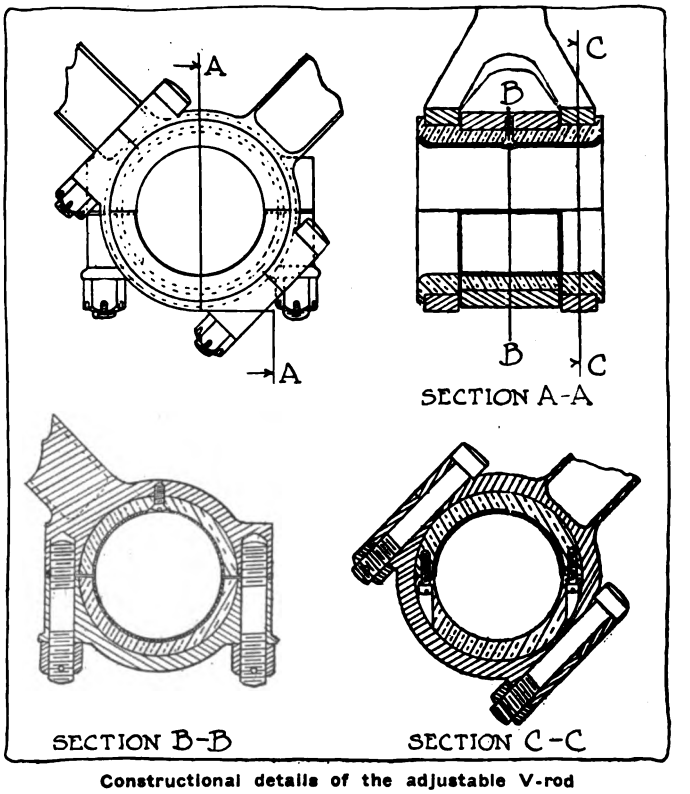
The design of this rod is also arranged to minimize wear between the forked rod and the bearing upon which it works. This provision has been made by having the projected area of the forked rod bearing surface about two and a half times that of the projected area of the piston pin bushing, and at the same time inherent motor conditions provide an ample supply of lubricant for this oscillating joint as it is located at the bottom of the rod with the pressure upon the entire bearing equal to that at the wristpin.

Good Bearing Surface

The rod is designed to replace types which either have good bearing surface and no adjustability, or adjustability without good bearing area. By combining both features it is necessary to make some special provisions of construction, and it is this feature which is the subject of the patent on the new rod. In laying out the bearing surface of the new rod it is considered that the bearing stresses on the eight- and twelve-cylinder motors are generally less than on other types because the cylinder dimensions are smaller, and in order to obtain advantage of the lower stresses, the construction of this rod provides practically full crankpin bearing area for each cylinder. The bearing bushing is continuous across the entire top of the bearing with the adjustable features on the lower portions. In other words, an explosion in either of two opposite cylinders will work against a bearing which is the full width of the crankpin.

The rod shown in the accompanying illustration was designed for an eight-cylinder motor with cylinders at 90 deg. For a twelve-cylinder motor with the cylinders set at 60 deg., the main rod would incline at an angle of 30 deg. from the vertical instead of at 45 deg. as shown here. The assembly of the rods in the manner in which the adjustments are made are shown very clearly in the accompanying illustration. The shim adjustments can be seen by referring to the constructional and disassembled views. The bearing surfaces of the forked rod when bearing against bronze should be hardened, referring to the oscillating joint. A less expensive and, according to the maker, an equally satisfactory method will be found in leaving the forked rod unhardened and having the back of the bronze shell upon which the rod bears faced with babbitt. Owing to the greater radius of this bearing circle the area of the bearing is such that the babbitt will readily endure the stresses.

The rod was shown to members of the Society of Automobile Engineers, during the recent cruise on the Great Lakes, and attracted attention from those on board who were interested in the design of V-type motors. It is stated that negotiations are under way at the present time with several concerns. The manufacturer states that the cost of the rod will about equal that of present types.



Constructional details of the adjustable V-rod

The Rostrum

Cadillac Eight Geared 4.42 to 1 Direct

EDITOR THE AUTOMOBILE:—Which gear ratio would you recommend for a Cadillac eight? It is desired to make the performance of the car as good as possible considering reduction of wear, avoidance of extreme speed, and as little gear changing as possible. The car is to be driven at an average speed of about 15 to 25 m.p.h. on roads of the kind to be found about New York City within a radius of 100 miles. The car would carry the usual load of five people, two spare tires, tools and kit, and the gear ratios I am considering are 4 to 1, 4.5 to 1, 4.75 to 1 or 5 to 1.

This query is in line with a determination to secure the utmost life of the car in good condition and with its maximum power. At the same time it is desired to have a car which does most of the work on high and which can run at high speed if necessary without the great engine speed which is now necessary.

2—Does the oversize tire 37 by 5 as against 36 by 4½ really return the value in increased wear? What is the effect on the speed and power of the car oversize equipped?

Mt. Vernon, N. Y. L. M. S.

—The Cadillac eight uses a gear reduction of 4.42 to 1 which is designed to meet just the requirements which you mention. When the engineering department of a concern selects a definite gear ratio, all the requirements which you have mentioned as well as a great many others are carefully considered. Therefore, you need not worry that the gear reduction will not be correct for the roads which you will find within a radius of 100 miles of New York City. The motor of the Cadillac car is designed for high speeds and with the even torque and good balance, should run several thousand miles before any adjustment is needed and before any drop in power is noted. When it is, it can be restored to its normal condition by valve grinding and bearing adjustments the same as any other car.

2—The oversize tire generally returns to the purchaser in added mileage more than the difference in cost between that and the straight size tire. The effect on the power and speed with a motor of the power of the Cadillac eight is unnoticeable.

Racing Car Gasoline Mileage Is Low

Editor THE AUTOMOBILE:—Will you kindly advise me as to the number of miles the average racing car goes to the gallon of gasoline?

Greenville, S. C. E. B. S.

—The number of miles per gallon varies so greatly, that any fixed figure cannot be taken as applicable to all sets of conditions. The reason for this is that in speedway racing such as at Chicago, speeds are so much higher than they are in road racing for instance, that the gasoline consumption for the same cars would be much different were the consumptions measured first on the track and then on the road. The piston displacement also varies to such an extent that a fixed figure could not possibly apply to all sizes of cars. With these circumstances in view, it is impossible to give a broad average fuel consumption figure for all gasoline cars, because if such a figure were taken based upon all races, it would mean absolutely nothing. In such races, as are held at Indianapolis and Chicago, where the piston displacements are limited to 300 cu. in., the gasoline consumption is somewhere around 6 miles to the gallon.

Holley 1-In. Carbureter on Flanders 20

Editor THE AUTOMOBILE:—Can you tell me of a carbureter which will work well on a Flanders model 20. If so, would I have to get a new intake manifold?

2—Would you advise placing a larger carbureter on. If so, what size?

Browns Valley, Ind. C. S. W.

—The carbureter used on the Flanders 20 is the Holley 1-in. and this gives perfect satisfaction, if it is in good condition, in connection with the special design of manifold used on this model. It is therefore unnecessary to change either the carbureter or manifold.

2—If you put a larger carbureter on your Flanders you would not get any satisfaction at all, for too large a carbureter results in an impossibility of proper adjustment, and hence in very imperfect performance.

Two Sets of Brakes Are Necessary

Editor THE AUTOMOBILE:—We would like information concerning brakes for automobiles. As all automobiles are supplied with two sets of brakes, one called the service brake and the other the emergency, both of which act on the hind wheels, why is it necessary to have both? If the service brake will hold the wheels securely from revolving if necessary, surely the additional use of the emergency brake could do no more, and if so, why have both?

Beacon, N. Y. M. P. B.

—Either brake should be sufficient to lock the wheels and

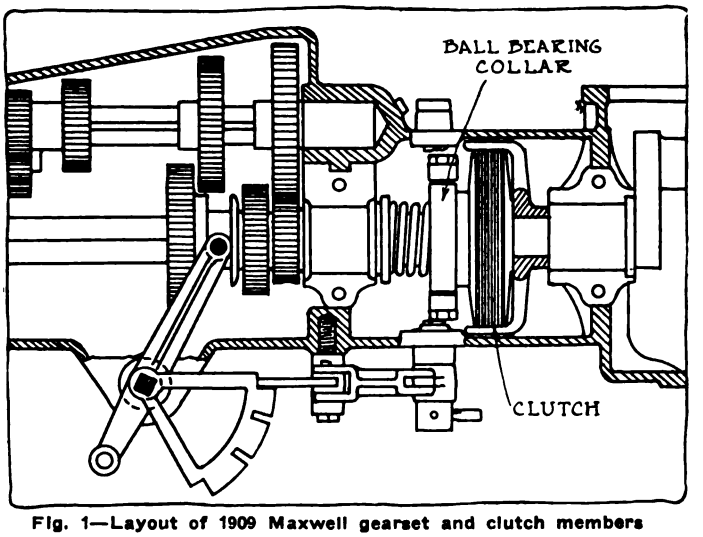


Fig. 1—Layout of 1909 Maxwell gearset and clutch members

hence, as you say the additional use of the emergency brake could do no more. An emergency brake is necessary however, because it is equipped with a ratchet which holds it on when the car is stationary and if the car is stopped on a hill, it is necessary to have such a brake on the car. Furthermore, should the service brake ever be in bad condition, so that it cannot operate, it is a safety precaution to have another brake on the car. The additional use of the emergency brake in stopping is not ordinarily necessary when the service brake is in working condition.

Motor Can Be Repaired at Low Cost

Editor THE AUTOMOBILE:—I have long been an admirer of the American underslung cars and would like to know if that concern sold their business to some other manufacturer as I have heard, and if so, is the American Tourist being manufactured under another name?

It has been said that the engine is of very poor quality. Is this so? What motor was used in the American Tourist 1911? What would be the best motor to put in this model when I desire to change it, considering horsepower, ease of installing, and at the least expense, etc.

Brockton, Mass. W. BREWSTER.

—The American Motors Co. has been discharged from bankruptcy. Whether or not the stockholders will endeavor to reproduce the car and to get it back into the manufacturing business is impossible to state at this time. The car referred to by you has a Teetor motor and this motor has given uniform satisfaction and is perfectly reliable. Therefore if you desire to put a new motor in, it would be one of the same make. There is no reason why you should place a new motor in the car however, as the one you have can no doubt be repaired for much less than it would cost you to put in a new one, and it would be advisable to take this matter up with the V. A. Longaker Co., 706 Merchants' Bank Bldg., Indianapolis.

Clutch Parts Are Probably Worn

Editor THE AUTOMOBILE:—I have a 1909 model D. A. Maxwell car with a multiple disk clutch that runs in oil and is giving me some trouble. When I engage the clutch it sounds and acts as if it would tear the car all to pieces. I have drained the clutch and washed it out thoroughly with kerosene and supplied new cylinder oil but it does not do any good. Can you tell me what to do.

West Liberty, Iowa. E. G. W.

—In all probability your trouble is due to the clutch shifter ball cup and cone which has become worn. These two parts form a bearing in the clutch containing twenty-seven ⅜-in. steel balls and whenever the ball cup or cone becomes worn a trifle, the ball bearing will tend to make the clutch itself rattle and slip. It would be well for you to have a competent mechanic to take this clutch apart to see just what parts are worn. A diagram giving an idea of the clutch is shown in Fig. 1.

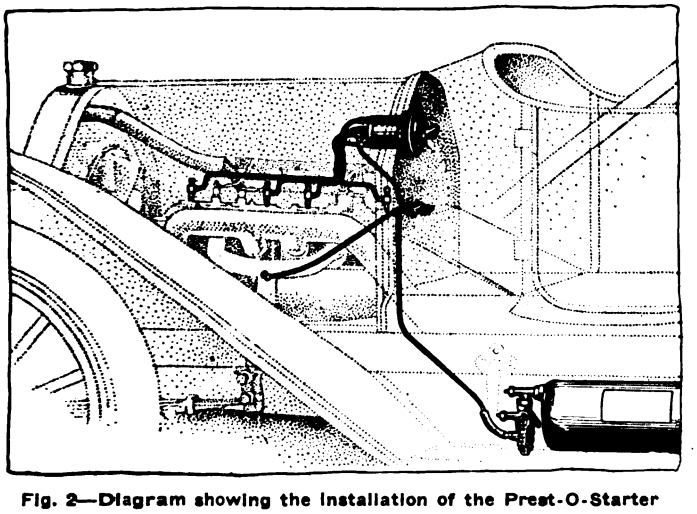

Fig. 2—Diagram showing the installation of the Prest-O-Starter

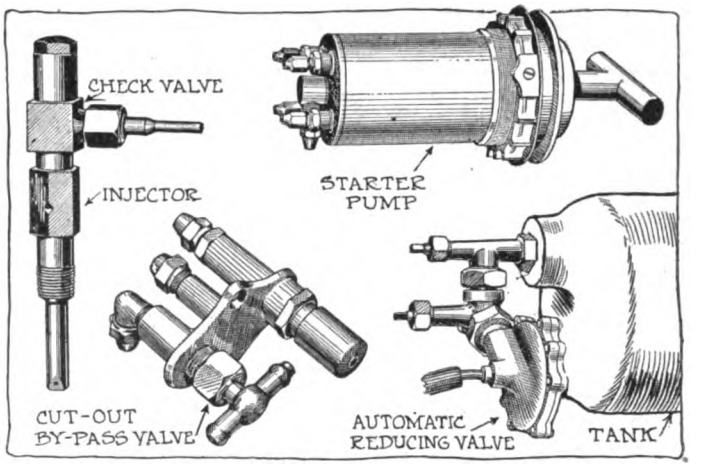

Fig. 3—Parts of the Prest-O-Lite acetylene starting apparatus

Rough Contact May Cause Trouble

Editor THE AUTOMOBILE:—Kindly give me information relative to a Ford engine as per the folowing:

When I short-circuit 1, 2 and 3 vibrating coils in the 1913 model, 4 vibrating coil seems to spark for each cylinder, though irregularly. If I change the position of the units, it makes no difference. I separated the wires, took out the timer and cleaned same. I tested out all the wires separately and found all the connections to be soldered and tight. Also put in a new wire from No. 4 coil to No. 4 on the timer and cannot see a change of any kind.

The vibrator No. 4 seems to work well when the dry cells are used, but when the magneto is used it vibrates about 6 to 10 times a second and causes the engine to miss. The plugs are all good, for I transferred them several times and can note no difference. The No. 4 contact in the timer is rough or wavy. Would that be the cause. A. J. B.

Balston, Pa.

—The symptoms you give for your trouble are rather indefinite, but if the contact in the commutator is rough or wavy, as you state, trouble is sure to develop and it is advisable to replace the commutator case. It would also be well to go over the wiring very carefully and make sure that the coil units in the dash coil are properly adjusted and in good condition.

Speed Depends on Varying Factors

Editor THE AUTOMOBILE:—Can you tell me which company makes the Sandbo starter? It is a hand starter operated from the seat. Can it be attached to a Studebaker model 20? Please give me diagram of same and price.

2—What speed can be gotten out of a Studebaker model 25, 1912 model if the wind resistance is reduced by putting on a racing body?

3—How much more speed can be gotten from a car by putting ether in the gasoline, and how much should be used?

4—How do the compressed air and Prest-O-Lite gas starters work? Can you give me a diagram of the latter?

Sterling City, Cal. ELMER MARION.

—The Sandbo starter is made by the Modern Specialty Co., Racine, Wis. This starter could probably be adapted to the Studebaker 20. A diagram of the starter as installed on the Ford is given in Fig. 4.

2—We have no records of anyone having made a racing car out of this model Studebaker and hence cannot predict the speed which can be made if this were done. Of course,

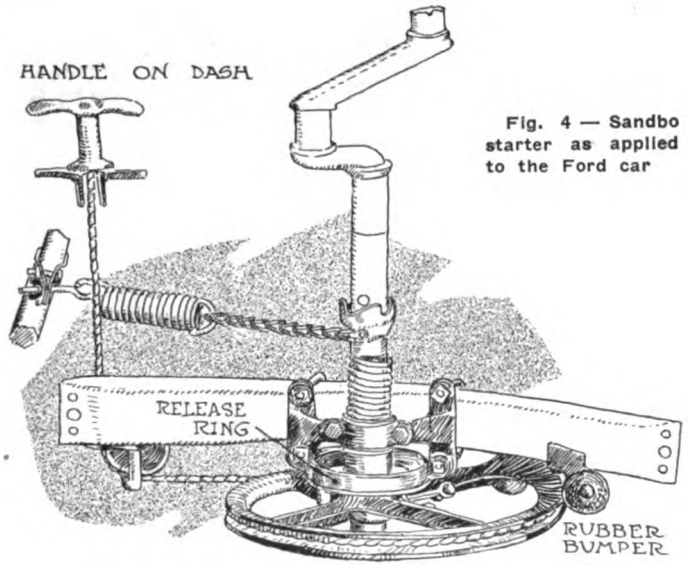

Fig. 4 — Sandbo starter as applied to the Ford car

the speed would depend upon the condition of the motor, the gear ratio provided, the weight, etc., and would vary with each of these factors.

3—THE AUTOMOBILE does not recommend the use of ether added to the fuel.

4—A Prest-O-Lite gas starter operates by injecting a charge of acetylene into the cylinder and then exploding this with a spark which starts the motor. Compressed air starters operate non-explosively by forcing a charge of compressed air into the cylinder in firing position allowing expansion of this air to rotate the motor and cause it to start. A diagram of the Prest-O-Lite gas starter is given in Figs. 2 and 3.

Secret Compounds Used for Float Covering

Editor THE AUTOMOBILE:—Would you please tell me what is used for covering or coating cork floats to keep them from getting gasoline or water logged. I believe that there is something better than shellac as was formerly used. The shellac forms in little blisters or air bubbles over the cork and then it allows the gasoline to get inside which makes them too heavy.

Laconia, N. H. W. E.

—Some of the carbureter companies are now using a secret compound for covering their cork floats. You can however, make a very satisfactory job with shellac by dipping the float instead of attempting to paint it on. The shellac is thinned with alcohol so that it will lie uniformly over the entire surface.

Wants History of Twelve-Cylinder Motor

Editor THE AUTOMOBILE:—Would you kindly give me a brief outline of the development of the twelve-cylinder motor, stating a few facts in connection with the history of the same? J. E. S.

New York City.

—The Packard and National twelves are the first commercial automobile engines of this number of cylinders to be built in the world. The National is mentioned along with Packard because its announcement came out at the same time. The twelve must, therefore, be regarded as an untried proposition so far as the stock automobile is concerned.

However, these motors are not the first to be used in automobiles, as, from the best information gathered, the twelve-cylinder Sunbeam racing car was really the pioneer twelve. This Sunbeam, which is an English car, is regarded as one of the fastest cars in existence to-day. This car has made a name for itself on the Brookland's track in England. The cylinders are cast in sets of three, two sets in a row and these two rows at a 60 deg. angle to each one, as in the new Packard. The cylinders are 3⅛ by 5⅞. This Sunbeam has shown it is able to go as fast as its tires will allow and has the one-hour world's record on the Brookland's track, covering 107 miles and 1672 yards. This record will probably stand for some time.

As is known, the Continental concern is about ready with three different sizes of twelve-cylinder motors and the Pathfinder and Davis concerns have already announced twelve-cylinder cars in addition to Packard and National.

The twelve-cylinder motor has been used in aeroplane work for some time, and there are several examples of the V-type as used by Packard and the rest. The most prominent of the aeroplane motors of twelve cylinders are as follows:

Renault	60 deg.	V
Sunbeam-Coatalen	60 deg.	V
Rausenberger	60 deg.	V
Johnson	90 deg.	V (two-cycle)

The last two mentioned are American makes. You can see from the above that the twelve-cylinder motor is really not a new construction, although it is new to motor car use.

The engineers who have adopted the twelve claim great advantages for it, and for more information you are referred to the article which appeared in the May 20 issue of THE AUTOMOBILE on page 888.

Noise Denotes Worn Clutch Parts or Gears

Editor THE AUTOMOBILE:—I have a 1912 Michigan model 33 car on which I would very much appreciate a little information. There is a noise which I think comes from the clutch, but I would like to know what it is exactly before I tear it apart. It sounds very much like the cogs breaking off, or a sort of a ratchet sound when you engage the clutch on low or second gear, no matter how slowly the clutch is left in. It does not do this on high gear; only a sort of grinding sound is heard. When this occurs on first starting out you can feel the vibration coming through the clutch pedal as if it was catching on something. It will also occur when you speed up on low or second gear and pull very hard with the clutch engaged. The engine is in good condition, but the transmission and rear axle are a little worn.

The clutch has had all kinds of lubrication from none at all to heavy oils and hard grease. Can you tell me exactly what oil it should have, and how much? The noise referred to only started to-day, but it is so loud and has so much effect upon the car that I know it must be attended to immediately.

Newport, Pa. J. F. DAVIS.

—From the information you give, it is not possible to state definitely where the trouble is, but it is very probably due to a worn clutch collar or a stripped or broken gear. Non-fluid oil should make a good lubricant with these bearings.

Rawhide Gear Would Quiet Old Car

Editor THE AUTOMOBILE:—On my 1909 Hispano-Suiza speedster the timing gears have recently and quite suddenly become noisy. The motor is a T-head 10 cm. bore and 12 cm. stroke (4 by 4¾). The crankshaft gear and the intermediate are steel, the two camshaft gears are bronze. All of them are intact, but have developed a little play. Would you think it proper to put in a rawhide intermediate gear?

San Juan, P. R. A. F. W. H.

—You could have a rawhide intermediate gear placed in position between the crankshaft and camshaft gears, and this would no doubt eliminate the noise which is troubling you at present.

Air Leakage Probably Causes Trouble

Editor THE AUTOMBILE:—What do you think is the trouble with my car judging from the following:

It will run well a couple of miles after starting, but will begin to miss fire on one of the cylinders so soon as the engine gets warm and will miss every time, unless I prime it.

Then it will run well for about one dozen revolutions and start to miss again.

2—Why will not some cars start without first putting gasoline in the priming cups?

3—Which is the best way to stop the engine, that is, so that it will start easily when again wanting to start it?

4—Are the Marathon engines, used in the Marathon cars, made by the Marathon Motor Car Co., Nashville, Tenn.? If not, where?

5—What is the horsepower of the Marathon car according to the S. A. E. rating? It is a four-cylinder, 4½ by 5⅛.

6—Which clutch is best on a car, the cone or the disk?

Carver, Minn. READER.

—Apparently there is an air leak in the cylinder which misses. You should examine this carefully, going over all connections of manifold to the cylinder and also going around the threads of the spark plugs and priming cup. With a rich starting mixture it is possible that an air leak does not have the effect of causing a miss, but as soon as the motor begins to run, expansion due to the heat in the cylinder, causes the leakage to increase and hence a misfire. Another possibility, is that the fuel line is clogged supplying only enough to start and then as soon as the motor is running, the excess is used up and the motor will not have sufficient fuel to run upon. A third possibility is that one of the valves of this cylinder either needs grinding or does not seat properly. This also should be examined and when looking for leaks you should not fail to inspect the bushings surrounding the valve stem.

2—The reason that some cars will not start without first priming, is that a sufficiently rich mixture is not being supplied at the start. This is sometimes due to carbureter adjustment and other times to manifold design, etc.

3—In stopping the motor to secure a rich mixture for starting, the throttle should be opened wide causing the motor to speed up and then the ignition cut off. If you have a dash priming arrangement on your car, if you will operate this on cutting off the ignition, a very rich mixture will be drawn into the cylinders.

4—The Marathon motors are manufactured in the Marathon factory, Nashville, Tenn., where extra motors can be purchased if desired.

5—The S. A. E. rating of the Champion model Marathon, 4½ by 5⅛ is 32.4 hp.

6—Neither clutch has any claim to superiority over the other as both are used in all grades of cars from the lowest price to the highest.

Testing Cylinders for Roundness and Wear

Editor THE AUTOMOBILE:—If cylinders and pistons are removed from the motor by what method can you determine that the cylinders are so worn that you would need to install new ones or have old ones rebored?

By what method can one determine as to whether or not the piston rings are worn or have lost their resiliency, needing new ones installed?

Dubuque, Iowa. W. E. C.

—The method which is easiest for determining whether or not cylinders are out of round, is to take a piece of wood or board and cut it so that two of the edges make an exact right angle. The length is made equal to the bore and the flat edge put up against one of the walls of the cylinder, the length being carefully cut off so that the wood will just fit into the cylinder. It is then turned around to different parts of the cylinders and if the clearance at the end varies, the cylinder is not round. A sketch showing this method is given in Fig. 5.

Another way in which the test can be made is by taking strips of brass shim metal of which the thickness is known and placing them at several points around the piston, note if the clearance between the cylinder wall and pistons is equal at all points.

Still another method is to take ordinary inside calipers and calibrate in several directions across the cylinder walls at right angles to the axis of the cylinder. If the width of bore is the same in all directions, the cylinders are round.

To determine whether or not, a cylinder can be properly rebored, it is necessary to know the thickness of the wall and the cost of having oversized pistons made. If the walls are thin, and the oversized pistons not easily procurable, it might be cheaper to buy new cylinders.

To determine the necessity of purchasing new rings, it is only necessary to examine the ring to see if it is worn thin and to spring it into the cylinder to note if the ends of the ring come closely together. The ends should be tight with perhaps clearance enough for the insertion of a sheet of paper between the ends.

Highest Priced Car Not Definitely Known

Editor THE AUTOMOBILE:—Who owns the Jay-Eye-See car and where was it built?

2—Who owns the Simplex Zip and where was it built?

3—Who are considered the best three body builders in America, and where are they located?

4—Are the Rothschild and Kimball bodies made in America, and if so, where?

5—What is the highest priced American automobile made?

6—What is the highest priced European automobile made, and what is the price?

7—Where is the factory of the H. W. Johns-Manville Co., located?

Reading, Pa. F. A. K.

—J. I. C. was built at the Case factory and according to the records we have at present is the property of Louis Disbrow.

2—The Simplex Zip was built at the Simplex factory and is at present according to what information we have on hand, the property of the Simplex Automobile Co.

3—We have never had any authoritative statements as to who the three best body builders are in this country. This must naturally be a matter of personal opinion.

4—The Kimball body is built by C. T. Kimball & Co., Chicago, Ill. The Rothschild bodies are made in Paris. France.

5—We have no record of what the highest priced car is in this country for the reason that some of the prices quoted are for chassis alone, and it would depend upon what body was put upon the car before the price of the entire car would be known. We have records of chassis such as the Crane selling for $8,000 for the chassis alone, but whether this is the highest or not we have no definite information.

6—We have no record of this.

7—The Johns-Manville factory is in New York City.

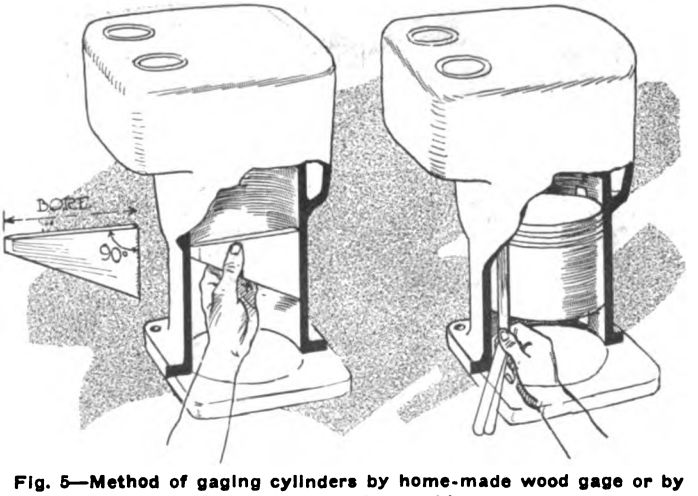

Fig. 5—Method of gaging cylinders by home-made wood gage or by feeler gage or brass shims

Chase Water-Cooled and Worm-Driven

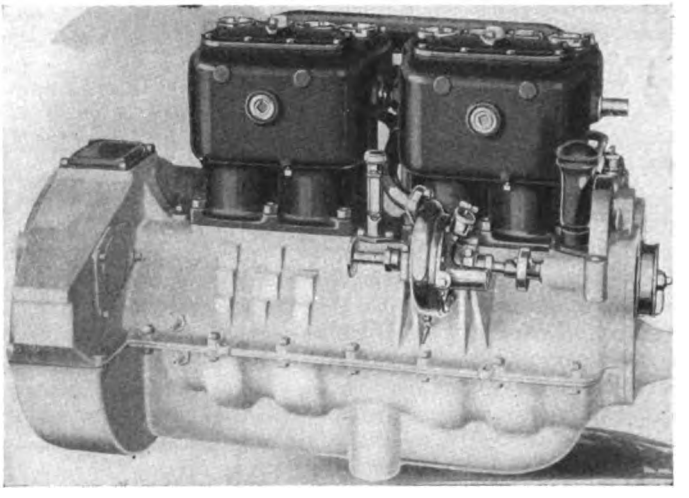
Three Models Ranging from 1500 to 7000 Lb. Designed to Meet Requirements of a Broad Field

ANNOUNCEMENTS of Chase motor trucks have been out for some time and show a complete revision of the line of the Chase Motor Truck Co., Syracuse, N. Y. In place of the air-cooled, chain-driven product a line of worm-driven designs with Continental L-head water-cooled motors has been substituted. All three cars which are being marketed under the names of Models T, R and O are of similar design, although of respectively ¾, 2 and 3½ tons capacity. With this line it is thought that the company will supply a truck for any demand whether it is of light, medium or heavy duty between the limits of 1500 and 7000 lb. The prices for the three trucks are respectively $1,500, $2,200 and $3,300.

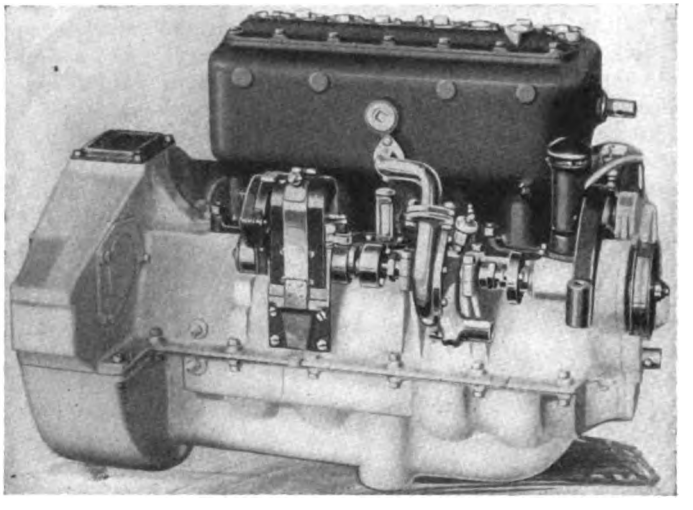
A Well-Balanced Line

From an engineering standpoint, the Chase company has put out a well-balanced line of standardized design which can at the same time fill the requirements of low price and mechanical efficiency. The same make of parts is used in every portion of the vehicle for all three models, although of necessity varying in dimensions for different capacities. At the same time, however, the use of the similar design has allowed the manufacturer to duplicate on many parts where the greatest capacity does not have a direct influence on the dimensions. For instance, the front axles of models R and O are the same and this duplication is carried through in many of the less important parts of the three cars.

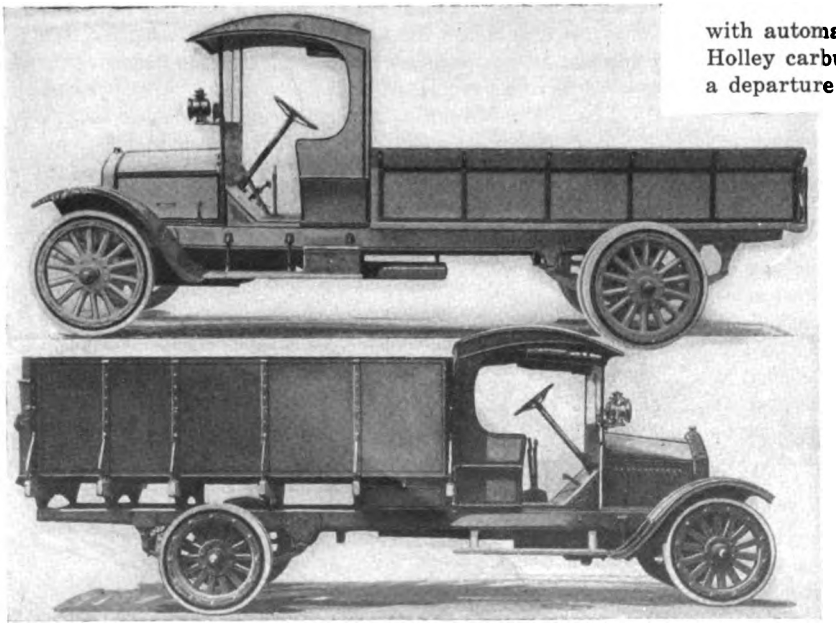
The ¾-ton truck model T has a four-cylinder 3.5 by 5 motor giving an S. A. E. rating of 19.6 hp. Model R 2-ton truck has the same design motor but the dimensions are 4⅛ by 5¼ in. The model O 3½-ton has a 4½ by 5½ motor. The S. A. E. ratings of the two larger types are 22.5 and 32.4 hp., respectively. All the parts of these motors are of standard Continental design with cast aluminum crankcases and three-point suspension features having the main frame arms at the rear and the trunnion part at the front. They are all fitted with automatic motor governors used in connection with the Holley carbureter. The radiators are the fin and tube type, a departure from standard design being made in the case of model O, which has a cast top bottom and side sections with fin and tube center core.



Continental motor used on Chase worm-drive trucks



Block-cast Continental motor for new Chase truck



Two representative styles of bodies supplied with the Chase water-cooled product

This radiator is mounted on springs to avoid twisting strains. On the T and R cars the radiators are built-up designs with the fin and tube core mounted on a pressed steel cross-member in front of the motor. The radiator mounting is cushioned to prevent jar.

All models are provided with Bosch high-tension magneto ignition. The gasoline systems are gravity and the tank capacities for T, R and O are, respectively, 16, 23 and 25 gal. The oil tank capacities are 1.75, 2 and 2.5 gal. The motor controls are standard.

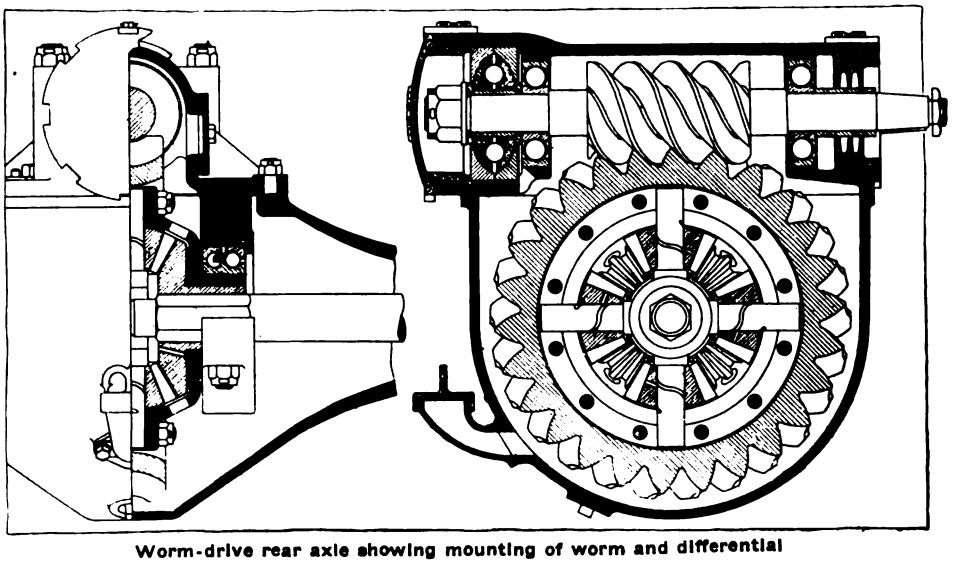
Dry Plate Clutch Used

In all three models the multiple disk dry plate clutch is used. These clutches are faced with asbestos and operate against saw steel. The power is transmitted through sliding gear-sets provided with center control, the bearings

in the gearset are Timken rollers and the gearboxes are mounted in a unit case with the motor. This insures a dust-proof connection between the two units. The gearsets are made by the Brown-Lipe Gear Co.

The New Worm Drive

Sheldon rear axles are used and in these are employed the new worm drive which has been adopted throughout this year's model. The worm and gear is a David-Brown type and is shown in the accompanying illustration. The differential mechanism is mounted in the worm gear and the whole assembly is carried on annular bearings with thrust bearings provided on the worm shaft and on the differential. The front axles are a design which is the product of the Chase engineering staff and are I-beam section, drop-forged with spring pads integral. The centers are dropped in a slight curve between the spring pads and high tensile strength gear steel is used for the spindles, which are heat treated and ground to take the wheel bearing.

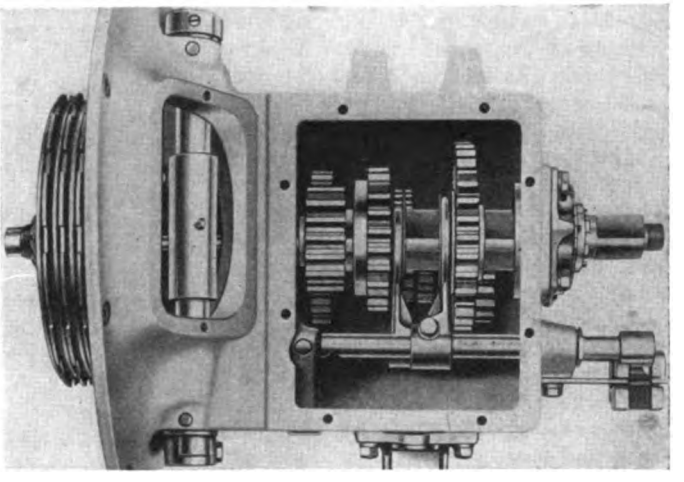


Worm-drive rear axle showing mounting of worm and differential

Semi-elliptic springs are used all around on all three models. These are all Sheldon products of alloy steel with the spring eyes bronze bushed. The spring bolts are hardened and ground and have large grease cups. The sizes of the springs vary for each model as follows:

Model	Front	Rear	Model	Front	Rear
T	2 by 36	2 by 48	R	2.5 by 38	2.5 by 52
O	3 by 38	3 by 54	Note:—Dimensions in inches.		

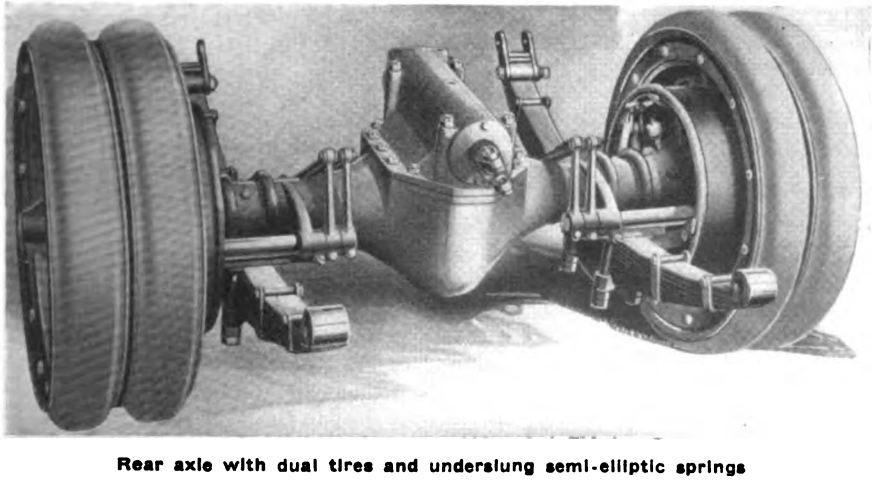
Hydraulic cold-pressed steel frames are employed and these are toed in at the front end to provide a short turning radius. The wheels on the three models are the same in diameter, being 36 in. The tire diameter, however, differs, as would be expected, for the different capacities. On the model T ¾-ton car, they are 2½-in. front and 3½-in. rear single. On the model R they are 3½-in. front and rear with the rear dual. The model O has 5-in. tires front and rear with dual rears. The wheelbases of the three trucks are respectively 135 in., 160 and 146 in.; and 175 and 148 in. The percentage of load on the rear axle as regards the weight of the vehicle itself for the models T, R and O are respectively 53, 59 and 63 per cent. The pay loads on the rear axle are respectively 82, 72 and 83 per cent.



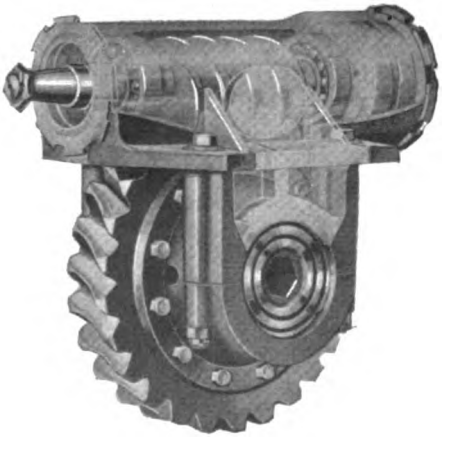
Clutch and gearset used on Chase trucks

Special Bodies to Order

Special tops and bodies are built to order to suit the requirements of any trade. The bodies are built in the Chase shops and in this manner special requirements of any concern can be met. For standardized work, however, there are standardized bodies some of which are shown in the accompanying illustrations. The cab and fenders are of substantial construction, the cabs having cast aluminum floors. The large models have standard cabs with curved tops, all fitted with windshields. Lamp brackets on these trucks are on the windshield frame. The feature of the largest is a tool box on the frame, on the right side, just back of the seat. These bodies, however, are subject to changes in order to meet the requirements of a given line of work.



Rear axle with dual tires and underslung semi-elliptic springs



Phantom of worm-drive

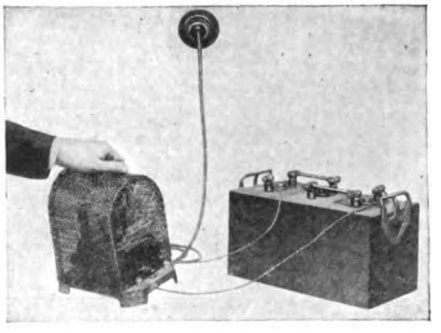
ACCESSORIES

G. E. Small Battery Rectifier

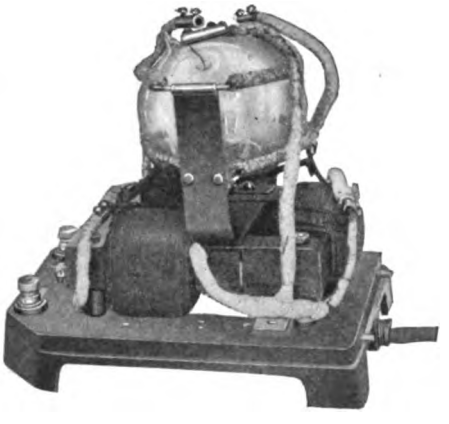
TO fill the wants of those desiring to charge small batteries from the current supplied by the municipal lines, which as a rule have alternating current, the General Electric Co. has brought out a small mercury arc rectifier selling at a price which is comparatively low for these instruments. The exact price of the instrument depends on the current cycles, that for the 60-cycle, 110-volt outfit being $22.50.

With this equipment the owner of a car fitted with electric lighting and starting is equipped to do his own charging. The rectifier is sold under the model name of S4K and is a compact unit with the coils and vapor tube mounted on a metallic base over which fits a perforated metal cap or casing. The entire 60-cycle unit weighs about 15 lb. and this fact together with the small size, 6½ by 9½ by 11 in., makes it readily portable.

The charging rate from the standard 110-volt supply is about 6 amp. The rectifier is put into operation by screwing a plug into any standard electric light socket and then attaching the negative and positive wires from the rectifier to their corresponding binding posts on the storage battery. The current is then turned on and the rectifier tipped sufficiently to complete the circuit in the mercury tube. After this no attention is required until charging is complete. The cost of charging is said to be about 25 per cent of the ordinary garage charge of 50 cents for a 6-volt battery. —General Electric Co., Schenectady, N. Y.



New G.E. rectifier for charging small batteries from alternating current



The new G.E. rectifier for small battery charging as it appears with the cover removed

Presto Electric Lantern

A two-cell hand lantern has been brought out recently, equipped with a 3-volt bulb and a 3-inch bull's-eye lens. It is a complete unit inclosed in a black enamel case 7 inches high, as illustrated. Some of the features of this light are that it can be turned on or off instantaneously and may be used either continuously or intermittently. It is supplied with a revolving head pivoting on the supporting bracket, so that it may be rotated to throw the light in any direction, either straight up or straight down, thereby being useful in such positions as directly beneath a car or for reading or writing. The lamp uses two ordinary 6-volt dry cells of cylindrical shape and is fitted with Edison Mazda bulb with a tungsten filament. The price of the lamp without batteries is $1.75.—Metal Specialties Mfg. Co., Chicago, Ill.

Presto electric hand type of lantern using two dry cells and having a 3-volt bulb and a 3-in. bull's eye lens

Ford Lamps, Brackets and Fenders

A new system for attaching the ordinary oil lamps to the 1915 Ford car consists of the use of a set of three malleable iron brackets, two for the side lamps and one for the tail lamp. They bolt to the projecting flange from the windshield, the side lamp brackets being made up in rights and lefts and taking the ordinary flat lamp bracket prop-holder. With these brackets any make of lamp can be used, a bolt-on type not being required. The brackets sell for $1.50 per set of three pieces.

A specially designed bolt-on electric side and tail lamp for Ford cars, having a screw and nut arrangement forming a support and part of the lamps and fitting into the flange bracket projecting from the windshield, has been put on the market by the same company. These lamps are finished in black and brass or black and nickel as desired. Side lamps list at $4.50 per pair and the tail lamp $1.20.

The same concern has also brought out a set of bolt-on type round oil lamps consisting of two side lamps and a tail lamp of new Ford type.

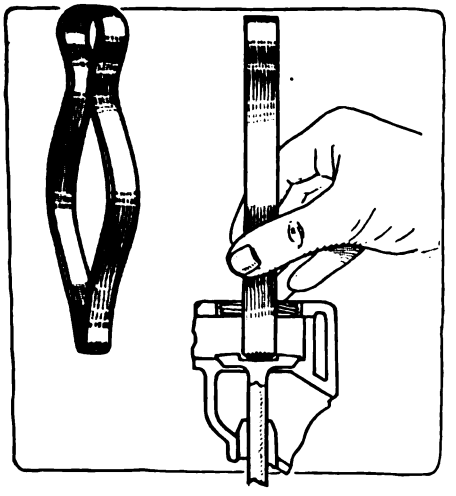
Rear fenders for Ford commercial cars made up in pairs complete with irons may be attached to any kind of delivery body. Fenders have the latest designed curve as in the 1915 Ford touring car fenders and are made of extra heavy steel. Fenders are finished in a triple coat of baked black enamel and are furnished with an inside flash apron. Packed in crates for shipment they sell at $9.90 per pair.—Superior Lamp Mfg. Co., New York City.

Handy Valve Lifter

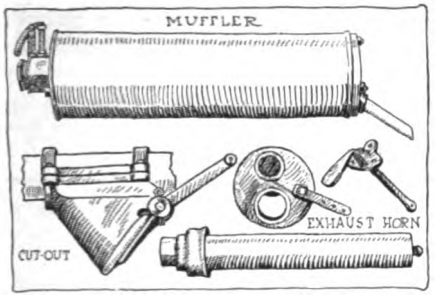
For removing valves after grinding a simple tool has been brought out under the name of the Handy valve lifter. It is in the form of a bent piece of spring steel shaped as in the illustration. When this is inserted in the slot in the top of the valve a pressure on the sides of the instrument expands the knurled tips and secures a grip on the slot of the valve, allowing it to be pulled directly from the cylinder. In some motors it is difficult to remove a valve by merely pushing up on the stem and should a quick push be used the valve will often strike some metal part of the motor or fall to the floor and become dented, thereby damaging its seat. With this tool the work of removing the valve can be quickly done and there is no danger of damaging the valve by allowing it to fall against some hard object. The price of the tool is 75 cents.—Fulton Co., Milwaukee, Wis.

Cutout and Muffler

The Gray cutout is designed to clamp directly to the exhaust pipe in which the proper size of opening has been cut to fit the opening in the cutout, which is turned downward and backward at an angle of 30 degrees to prevent the exhaust from striking the ground and raising dust. It comes in a number of sizes to fit the exact outside diameter of the exhaust pipe, and is made for a tight fit without the use of packing. A torsion spring on the valve holds the outlet door on its seat, and an extra coil spring is



Handy valve lifter for removing valves after grinding. Lifter is illustrated at left and method of operating at right



Top—Gray muffler for Fords with safety valve at front end. Lower left—Gray 30-deg. muffler cutout. Lower right—Gray Autochime exhaust horn

furnished with each cutout to be used when cars have an unsually strong exhaust.

The Gray muffler has outer drums of steel which are asbestos-lined, lock-seamed and riveted, while the heads are packed with asbestos wicking dipped in a special cement to make them gas tight. The front end of the muffler is fitted with a safety valve which remains closed under normal conditions but opens should an explosion occur within, and thus saves the muffler from severe strain. This muffler is now made in a special size to fit the brackets on a Ford car and furnished either with or without a cutout.

The same company manufactures several types of exhaust horn known as the Autochime. This is made to attach to the muffler pipe and exhaust pressure causes it to give out a powerful musical tone. It is furnished with fittings for attachment and an operating pedal.—Gray Hawley Mfg. Co., Detroit, Mich.

Noe Safety Tire Gage

The necessity for proper attention to the tires in order to obtain a maximum service and particularly proper inflation has long been recognized. As a result of this necessity the Noe maximum pressure safety inflating tire gage has been put on the market, the primary object being to provide a device which will positively prevent underinflation and which will insure the exact air pressure which a pneumatic tire is designed to carry and to automatically indicate at all times the maximum pressure within the tire.

The gage shown in the accompanying illustration, can be attached to any inner tube, inserted through the felloe of a wheel and inflated in the same manner aos the present inflating stem, remaining on the inner tube until replacement of the tube is desired, in which case the gage is removed and applied to the new or repaired inner tube. The gage is so hermetically connected to the inner tube that no leak is possible. It is water, tamper and trouble proof.—Seaman P. Noe, Asbury Park, N. J.

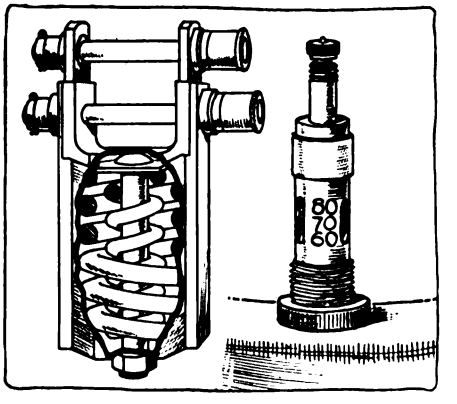
New Era Shock Absorber

This is a simple pattern of coil spring damper having two concentric springs of vanadium steel and an easily accessible adjusting nut, a long bearing is provided on the spring guides and lubrication is taken care of by large grease cups on the spring shackles. No castings are used in the construction, even the outer portion being cold drawn steel. The bushings are arranged so that the absorbers will fit practically any car without any difficulty and each set carries a *permanent* guarantee against defects. Prices vary according to size, the smallest costing $10 per pair and the largest $15.—Puritan Machine Co., Detroit, Mich.

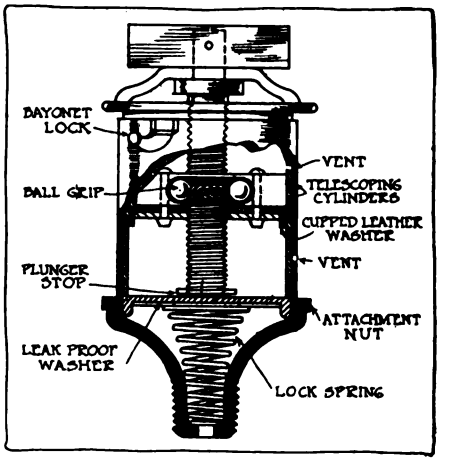
Bailey Grease Cup

An improved grease cup is one of the new C. B. specialties. A few of its features are an improved bayonet lock which cannot jar off and which permits quick filling; operates with thumb and finger only, no pliers or wrenches being needed; the plunger design prevents lubricant passing it; vent holes make ease of operation and prevent grease from returning to the cup; a ball grip prevents the plunger from turning; and the grease is forced into the bearing, a a leak-proof washer solving the problem of cleanliness.

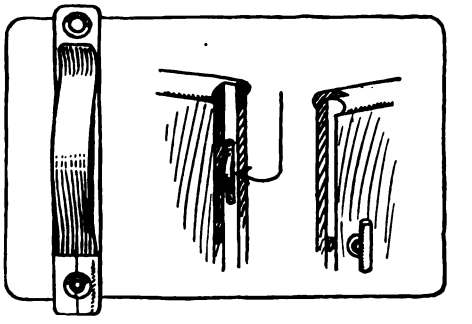
This cup is made in four sizes: ⅝-in., ¾-in., ⅞-in., and 1 in. diameter. Standard ⅛-in. and ¼-in. pipe thread, and 5-16-32 S. A. E. are supplied. The cups which are made only in brass, polished or nickel plated, range in price from 30 cents for the ⅝-in. polished brass to 45 cents for 1-in. in the same metal and from 35 cents for ⅝-in. nickel plated to 50 cents for 1-in. of the same metal.



Left—New Era coil spring shock absorber. Right—Noe safety tire gage



Section through C.B. bayonet lock grease cup which is designed to prevent jarring off and to permit of quick filling

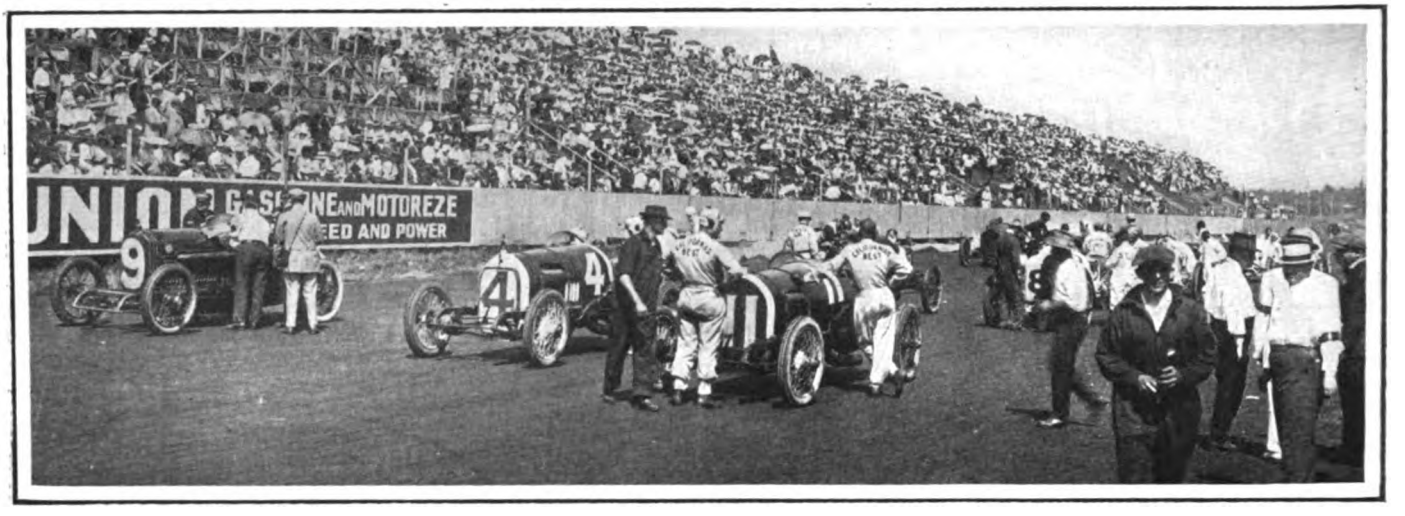


C.B. device for preventing car doors from rattling and to throw them open when unlatched

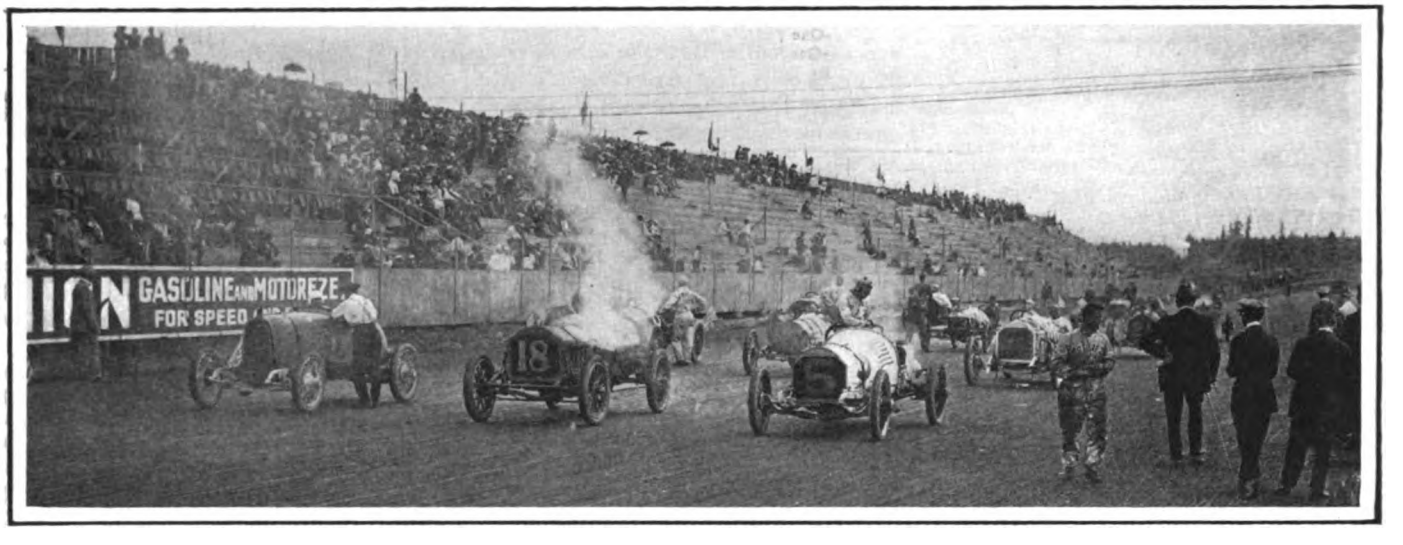
A device for eliminating rattle on the doors of cars is one of the new C. B. products. This device consists of a strip of high-grade clock spring steel attached in a minute to the door-stop with two small screws and which serves as spring and a dampener of noise when the door of the car is closed. It not only allows easy closing of the doors without noise but also throws open the door when unlatched. The price, including the screws, is 25 cents.

Another anti-rattler made especially for use on Ford and other cars not having wood angle stops is included in the C. B. products. This is of the coil design and is made of high-grade piano wire. A small disk attached to the door strikes the coiled spring when the door is closed the spring in turn acting as a dampener of noise by its reaction on the disk. The spring tension also throws open the door when unlatched. Both anti-rattlers are guaranteed for the life of the car. The price of the latter variety, including the screws, is 20 cents.—Wm. J. Bailey, Newark, N. J.

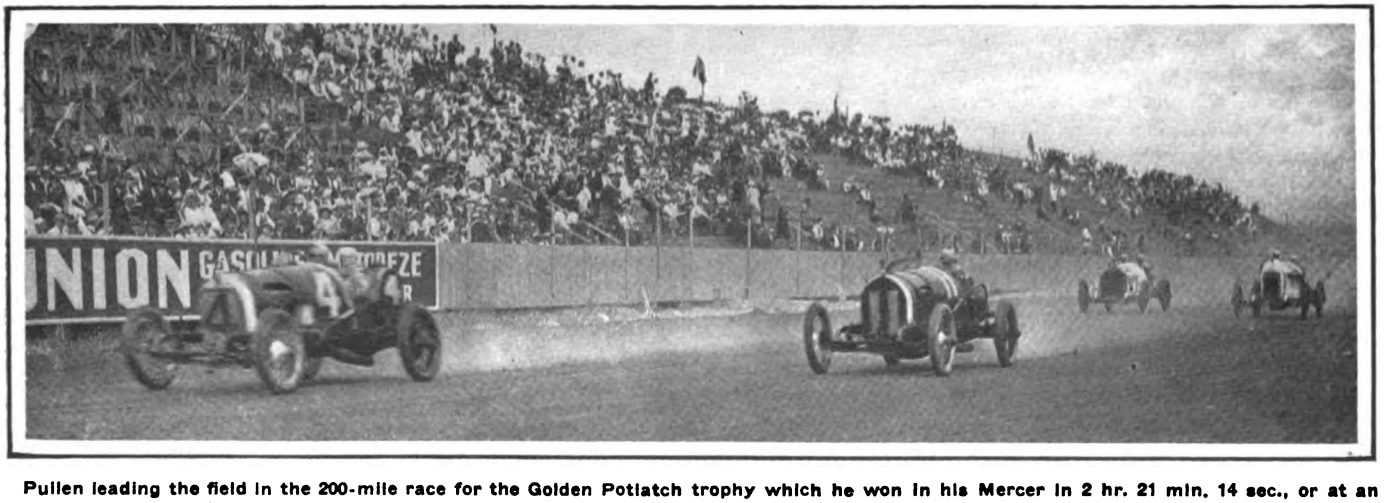
Glimpses of the Tacoma Races



Making ready for the flying start in one of the races held on Tacoma's new 2-mile board speedway over the Fourth of July holidays. The main feature of these races was the greatly increased average speed of the winners over that of former years, due to the new plank surface being more adapted to high speeds and less conducive to skidding than the old dirt surface



Start of the Montamarathon 250-mile race on the Tacoma speedway which was won by Ruckstell in a Mercer in 2 hr. 57 min., or at an average speed of 84.5 m.p.h., which was 11.1 m.p.h. faster than the time made by Cooper, who won this race in the Stutz last year. This year Cooper was second, again in the Stutz, covering the 250 miles in 2 hr. 58 min. 5 sec., or at 84.22 m.p.h.



Pullen leading the field in the 200-mile race for the Golden Potlatch trophy which he won in his Mercer in 2 hr. 21 min. 14 sec., or at an average speed of 85.2 m.p.h., 11 m.p.h. faster than the time made by Hughes' Maxwell in 1914. Cooper in the Stutz was second in this event as well as in the Montamarathon, his average being 85 m.p.h., while Ruckstell was third in the Mercer with 79 m.p.h.

The Cylinder Question

UP to the present nearly all car makers have aimed at one goal, namely, making cars with the same number of cylinders irrespective of the size of the car and the total piston displacement of the motor. First the four set the pace and all small cars, one by one, dropped the single and two-cylinder design and got into the four-cylinder ranks. Later, when the six established itself, the majority of four-cylinder makers of small cars started changing from fours to sixes, believing that they could not sell the four, no matter how small it was. They contended that the purchaser of the smallest car wanted a six, because that was what the wealthy purchaser had.

To-day we are witnessing a transition from sixes to eights and twelves, and already there are evidences that a few small cars are going to change to more cylinders. This constant change suggests the possible time when makers will not talk so loudly on the number of cylinders but when cars will be sold on performance, and it is really on performance that some of the new cars with more cylinders are being sold. The buyer wants performance, and the sooner he ceases to buy solely on the number of cylinders the better.

What difference should it make to the buyer whether he has four, six, eight, or twelve, providing it gives the best maximum performance, providing it gives desired acceleration, providing it gives high-speed performances with the greatest ease and absence of vibration, and providing the maintenance of the car is at the lowest mark? These are the important considerations. Two engineers may approach these subjects from different viewpoints, and the only criterion of their success should be the performance of the machine and not the simple question as to whether it has four, six, eight, or twelve cylinders.

More Official Tests

WITH changes in designs of motors and other car parts the importance of official tests such as made by the Packard twelve on the Chicago speedway last week becomes more apparent. Tests of this nature made by A.A.A. officials are the only tests that can be seriously considered by the public. Other tests made solely by the parties concerned invariably have a reverse influence in that the tests are not accepted by rival makers, and the selling forces throughout the country begin a campaign of discrediting the entire affair, and with a certain amount of right to do so. Such conditions are not desired, they should be avoided; we cannot afford to sow the possibilities of deception so broadcast. Let our public have official facts, facts that the rival maker cannot take exception to, facts that are indisputable.

This example of a concern coming out publicly and establishing its standards for speed, economy, etc., should be imitated. It is so immeasurably superior to other methods that comparisons are out of place. It is a business method as compared with publicity tactics, where a would-be standard is attempted out of the performance of some individual in the organization.

Hopeless Instruction Books

THE average instruction book to-day is a treatise for an engineer and not an educational book to be put into the hands of the owner, the chauffeur, the garageman, or the repairman. The books are poorly written, very often not well arranged, and in all cases quite uninteresting. Naturally they fail in their mission, and it is not surprising to find that they are not read or studied as they should be.

Instruction books should be in two parts, one a purely educational one and the other a semi-engineering treatise for the dealer, the expert repairman, and the garageman, who should know the ins and outs of all cars. The latter book would also be well suited to the engineering owner.

The educational book would be a purely educational one on the particular car or model and should not combine two or three models made by the same concern. This should aim at analyzing the entire car for the average reader, in a word, a dissertation on the car, which will result in the owner giving the car rational usage and perhaps directly resulting in the car giving much more mileage than it otherwise would.

Miles Host to N. A. C. C.

Directors and Friends Spend Three Days at His Maine Country Home

CHRISTMAS COVE, ME., July 13—The annual summer session of the National Chamber of Commerce, Inc., is in session here at the summer home of Samuel A. Miles, who in addition to officers and executive committee, is entertaining other leaders in the industry, the entire party aggregating thirty-five. The usual program of fishing, swimming, baseball and other sports is in force, two days being given over to holidaying and one day to the business of the chamber. Mr. Miles has every facility for entertainment at his big estate here with its miles of lake front, its salt water swimming tank, and all of the other essentials.

At to-day's business session of the directors, records of the traffic department of the N. A. C. C. showed that carload shipments of automobiles for June were more than 100 per cent greater than for the same period of last year. The figures are 15,308 carloads as against 7492 carloads for June, 1914.

There was an encouraging report of the desire of almost all the makers to have a uniform time for announcing annual models and some interesting data supplied relative to the progress being made on standardizing automobile treads and on the tendency of legislative bodies to give the jitney bus a fair hearing before passing laws affecting its operation.

Among those entertained by Mr. and Mrs. Miles are: Charles Clifton, C. C. Hanch, Thos. Henderson, Chas. Thaddeus Terry, Carl P. Pelton, J. Walter Drake, Wm. E. Metzger, H. H. Rice, Alfred Reeves, C. M. Hall, Chas. E. Thompson, James H. Foster, H. M. Swetland, F. A. Nickerson, R. D. Garden, Albert L. Pope, Wm. M. Sweet, Thos. J. Wetzel, T. C. Billings and D. J. Post.

Indiana Oxygen Co. Formed

INDIANAPOLIS, IND., July 8—A new firm recently organized here is the Indiana Oxygen Co. Four men form the organization. They are G. D. Armstrong, formerly general superintendent of the Prest-O-Lite Co., L. L. Sinclair of the same company, and W. L. and J. R. Brant. The company produces oxygen and hydrogen by the electrolysis system. A welding department for automobile repairing is a feature of the establishment.

Fisk Running at Full Capacity

CHICOPEE FALLS, MASS., July 9—The Fisk Rubber Co. is running at full capacity, its daily output being 5000 tires. It is expected that the company will show earnings of $1,500,000. These profits would contrast with $782,000 in 1914 and would represent a surplus for the common after paying 7 per cent on the $5,000,000 of preferred stocks of around 15 per cent. The common is not likely, however, to be placed on a dividend basis as the result of this year's good business. The company has a considerable floating debt and there is need of digesting its rather rapid growth before taking care of the claims of the common stockholders.

Overland's Morrow Plant to Be Enlarged

TOLEDO, O., July 9—The Morrow Mfg. Co., Elmira, N. Y., where Overland parts are made, is to be enlarged immediately by one-third its present size and capacity. The list of more than 2000 employees will be proportionately extended.

By Sept. 1, the Willys-Overland Co. will have an output of 600 cars a day at the local plant. Within less than 1 year the company expects to manufacture and ship 1000 cars every day. The company now has more than 11,000 factory and office employees in this city. A night force of 1500 workmen is laboring to increase the plant's output. The company now is 26,000 cars behind orders received.

Kalb Kelly-Springfield Engineer

SPRINGFIELD, OHIO, June 9—L. P. Kalb has been appointed engineer of the Kelly-Springfield Motor Truck Co., this city. He was formerly connected with the engineering department of the Pierce-Arrow Motor Car Co., Buffalo.

W. C. Guilder has been appointed factory manager in charge of production. He was for several years in the same capacity in the Mack truck factory in Allentown, Pa.

C. F. Gardner has been appointed an assistant to the president, J. L. Geddes.

Sternberg Changes Name to Sterling

MILWAUKEE, WIS., July 10—The Sternberg Motor Truck Co., originally incorporated as the Sternberg Mfg. Co., Milwaukee, Wis., has again changed its corporate title, the new style being Sterling Motor Truck Co. The change is made to conform with the adoption of the name "Sterling" as the trademark on its motor trucks.

Kennedy at Studebaker Plant

DETROIT, MICH., July 8—Henry Kennedy, managing director of the Studebaker Corp., of Australasia, Ltd., Sydney, Australia, has arrived at the Studebaker plant.

New S. A. E. Standard Ballots Out

Reports of Seven Divisions for Vote—Entire Schedule Expected To Be Approved

NEW YORK CITY, July 12—Ballots for the new S. A. E. standards have now been mailed to the members and upon the results of this voting will depend the fate of many new standards, although it is expected that the schedule will go through practically without exception owing to the care with which the standards committee has prepared the reports. The ballots are to be cast before Aug. 16. The reports of the seven divisions which are to be voted upon are those covering carbureter fittings, electrical equipment, electric vehicles, iron and steel, miscellaneous, springs and bell housings. These reports are all printed in the June Bulletin of the S. A. E., and have been digested in THE AUTOMOBILE.

The complete list of details follows:

Sixth Report of Carbureter Fittings Division

Flanges for ½-in. and ⅝-in. carbureters. Flanges for 2½-in., 3-in. and 3½-in. carbureters. Carbureter air heater.

Seventh Report of Electrical Equipment Division

Bulb bases, sockets and connector plugs.

Second Report of Electric Vehicle Division

Motor voltage. Motor name-plates. Number of cells in standard battery equipment.

Seventh Report of Iron and Steel Division

Revised vanadium steel specifications. Specification 3330—nickel chromium steel (new). Revised steel castings specification. Elimination of gray iron casting specification. Revised notes and instructions on steels.

Sixth Report of Miscellaneous Division

Flat fan belt and pulley widths. Cotter pin sizes. Brake lining sizes.

Fourth Report of Springs Division

Nomenclature of cantilever springs. Tests for parallelism of eyes and master leaf. Eye bushing and bolt tolerances. Wrapped eyes. Width of spring ends. Frame brackets. Offset of center-bolts. Nuts for spring clips. Center-bolts. Center-bolt nuts. Spring widths.

Report on Bell Housings

Number of bolts. Flange widths. Bolt hole circle.

Jarrard to Handle Apperson Sales

NEW YORK CITY, July 10—T. E. Jarrard, vice-president of the Apperson Bros. Automobile Co., Kokomo, Ind., is in charge of the sales department; assisting him will be J. H. Newmark, who also continues in full charge of the advertising department.

Hutchison Joins Gibson Co.

INDIANAPOLIS, IND., July 18—H. D. Hutchison, who has been in charge of the motor department for the Chicago district of the General Electric Co., has accepted the place of sales manager of the same department of the Gibson company, Overland distributor here.

Record Truck Exports for May

Pass $10,000,000 Mark—2,426 Trucks Valued at $6,583,912 Shipped

WASHINGTON, D. C., July 13—*Special Telegram*—The department of Commerce to-day announced that 2426 trucks valued at $6,583,912 and 4921 passenger cars, valued at $3,971,483, were exported in May.

This breaks the previous record made in April, 1915, when the $8,000,000 mark was passed.

During the 11 months ending May, exports were valued at $46,889,835, divided up into 11,006 trucks at $30,561,880 and 19,462 passenger cars at $16,327,955.

Comparing the same month in 1914 the large increase is shown. For the month of May, 1914, there were only ninety-nine trucks, valued at $127,024 and 3157 passenger cars, valued at $2,857,601, exported. During the 11 months' period ending May, 1914, the exports were 694 trucks, $1,061,354, and 26,324 passenger cars, $23,522,081.

—

International Standards May Be International Co-operation Division

NEW YORK CITY, July 9—It has been proposed in the council of the Society of Automobile Engineers to change the name of the International Standards Division to International Co-operation Division. If approved by the members of the council, this change will take place immediately.

The reason for making this change is that at the time the International Standards Division was created by the council, a communication was written abroad advising the British Engineering Standards Committee of the creation of the division. At that time the British body inquired as to the activities of the division in view of the use of the word International. After an exchange of communications, it has been found that the original title of the division is misleading from a European point of view, and owing to the possibility of future misunderstandings, and as a result of a conference between Chairman Zimmerschied of the Standards Committee, Chairman Clayden of the International Standards Division, and Coker Clarkson, general manager of the S. A. E., it has been decided to put the question to a vote by the council.

—

King to Make No Changes for 1916

DETROIT, MICH., July 12—The King Motor Car Co. has decided not to make any changes, either in construction or in price, in its eight-cylinder car until the end of this year. This is in accordance with the new policy recently adopted by the company.

During the first six months of 1915 the King company has built and sold about 3500 cars. The first eights were shipped about Jan. 15. It is expected that during the second half of this year the production will total about as many cars as during the first half of the year. Officials say that the business outlook is very good, dealers reporting conditions to be most satisfying in practically all parts of the country.

—

11,895 Cadillac Eights Shipped First Half of 1915

DETROIT, MICH., July 9—During the first half of 1915 the Cadillac Motor Car Co. manufactured and shipped a total of 11,895 eight-cylinder cars. This is the biggest production for a period of six months in the company's history.

The first Cadillac eights were shipped in October, 1914.

The production records show that 7043 cars were made in April, May and June, as compared with 4852 during the preceding three months. Taking the figures month by month, the output was 1321 in January, 1575 in February, 1956 in March, 2325 in April, 2519 in May and 2199 to June 26.

—

$50,000 Additions to Chalmers Plant

DETROIT, MICH., July 12—Two permits for two factory additions to the Chalmers Motor Co. plant were granted last week, involving an expenditure of $50,000. Factory building No. 4 will be enlarged by second, third and fourth story reinforced concrete additions, while factory building No. 5 will receive a four-story addition.

—

Barton Top's New Plant

DETROIT, MICH., July 12—The Barton Auto Top Co. will move into its new plant, a one-story structure 65 by 140 ft., during the latter part of July. This plant is located to the rear of the present quarters, which are at 863 Woodward avenue, and which will very likely be maintained as offices.

—

Gadabout Leases Detroit Plant

DETROIT, MICH., July 12—The Gadabout Motor Corp. of New York has leased a two-story factory building at 182 Lafayette Avenue.

—

Graham Leaves Bower

DETROIT, MICH., July 13—D. F. Graham, for four years sales manager of the Bower Roller Bearing Co., has severed his connection with that company.

W. S. Bennett, who was assistant sales manager has become sales and advertising manager of the company.

24,000 Reo Cars for 1916 Season

Plans for Factory Additions Extended — New Truck Plant—Loading Dock

LANSING, MICH., July 9—General Manager R. H. Scott of the Reo Motor Car Co. states that the Reo company will build 24,000 passenger cars for next year. Fifteen 2-ton trucks are being shipped daily. Work has been started upon a tract of 4½ acres of ground for the erection of a large new plant for the truck organization.

The additions to the Reo plant announced several weeks ago will be more extensive than originally planned. They will consist of a three-story structure, 101 by 256 ft., with basement, being an addition to the general assembling department; to the final assembly department there will be added an entirely new addition, three stories in height, 115 by 138 ft., with basement, while the present assembly building will receive two additional stories, 80 by 153 ft. A three-story addition, 50 by 74 ft., will be added to the engineering building. Shipping facilities will be greatly relieved through the construction of a loading dock along the Grand Trunk railroad, 347 ft. long and 36 ft. wide.

—

$1,000,000 Austin Co. to Make Two-Speed Axles—Seek Plant

GRAND RAPIDS, MICH., July 10—The Austin Automobile Co. will probably be incorporated with a capital stock of $200,000, while another company is to be organized having a capital stock of $1,000,000 to manufacture the Austin two-speed axles. A larger plant is also being sought.

—

Kelly E. A. M. A. President

CLEVELAND, O., July 9— G. H. Kelly, secretary of the Baker R. & L. Co. was elected president of the Electric Automobile Manufacturers' Association at the annual meeting in this city, held recently, to succeed L. E. Burr of the Wood company.

—

Couzens Joins Pathfinder

INDIANAPOLIS, IND., July 8—St. Clair Couzens, until recently advertising solicitor of the *Chicago Daily Journal*, has joined the Pathfinder company as assistant director of sales and advertising.

—

Kenworthy Baker-R. & L. District Mgr.

NEW YORK CITY, July 10—C. Y. Kenworthy has been appointed eastern distric manager of the Baker-R. & L. Co. Mr. Kenworthy was formerly manager of the Rauch & Lang Co. in this city.

Registrations Break All Records

Iowa Passes 130,000—Close to California's 137,000—New York Over 200,000

DES MOINES, IOWA, July 14—Automobile registrations in Iowa for 1915 have passed the 130,000 mark, thus making a large gain on California, whose registrations up to July 3 numbered 137,383. The amount of fees received from registrations has passed the $1,000,000 mark.

New York State is still in the lead with a record registration of 200,189 cars. The receipts for the first half of this year for New York were $1,667,000, against $1,533,367 for all of 1914.

Iowa's 1914 registrations numbered only 106,087. It is estimated that there will be a total of over 150,000 before the close of 1915. The total receipts last year were only $1,040,000 and more fees were received in the first six months of this year than during the entire year of 1914.

Iowa farmers contributed $1,000,000,000 to the general wealth of the Hawkeye State as a result of the bumper crops of 1914. Its wealth per capita, figuring on farm wealth alone, is $1,682.

—

Chicago Wheel Tax Must Be Paid by July 20

CHICAGO, ILL., July 12—Beginning July 20 Chicago motorists will have to have their wheel tax paid or be hailed into court by the police, as announcement has been made that after that date the Chicago wheel tax ordinance will be enforced. For the last 2 months car owners have not been obliged to pay a wheel tax because the measure was declared unconstitutional. Now that a new law has been passed by the legislature, the old measure will be enforced. However, inasmuch as the law was inoperative during May and June, only ten-twelfths of the annual rate will be collected. For vehicles under 35 hp., the tax will be $8.34 instead of $10. This will be good until April 30, 1916. Higher-powered cars will pay a proportionately higher rate.

—

Du Pont Co. Delivering Cars

NEW YORK CITY, July 12—Under the name of Du Pont Motor Car Co., the Sphinx Motor Car Co., York, Pa., has been re-organized. The factory of the Du Pont company is at York and a factory branch agency has been opened in New York City with the S. S. Shears selling organization. It is stated that the company has French affiliations and will endeavor to do an export business. S. S. Shears, who is vice-president of the Du Pont Motor Car Co., is in charge of the sales in the East and the company at the present time is disposing of the 1915 model at a price of $595 preliminary to bringing out a 1916 type which will be announced, it is stated, in about six weeks.

The present car specifications include a Lycoming 3¼ by 5, L-head block motor with Covert gearset, Spicer joints, Weston-Mott axle, Hyatt bearings, Schwartz wheels, demountable rims, Connecticut ignition, Splitdorf-Apple lighting and starting, cantilever springs and wheelbase of 112 in., with five-passenger body. Cooling is by thermo-syphon; ignition, Atwater Kent; drive, left; control, center; and the spring suspension, cantilever front and rear. The springs are the product of the Sheldon company. The car is sold fully equipped, the price being f.o.b., York, Pa.

—

9249 Cars in Louisiana

BATON ROUGE, LA., July 9—Up to July 1, there were 9249 automobiles registered in the State of Louisiana, approximately 9175 of these being gasoline passenger cars; 460 gasoline motor trucks and about seventy-five electric passenger machines. No electric trucks were registered. About $59,000 in fees was collected by the Secretary of State, no fees nor registration being required for chauffeurs. Approximately 120 re-registrations are recorded, but there are no non-residents registered.

—

Michigan Has 99,460 Cars

DETROIT, MICH., July 13—Up to July 10 the Secretary of State of Michigan, has issued 99,460 automobile licenses, which is 23,138 in excess of the total number issued in 1914. It is anticipated that the estimate made early in the year that 120,000 cars will be licensed this year will even be below the actual count by Dec. 31.

—

Twin Cities in Need of Uniform Laws

ST. PAUL, MINN., July 8—Need of uniform laws governing automobile operation has been emphasized in the Twin Cities by the new dimmer law in St. Paul and the new jitney ordinance in Minneapolis. Motorists and jitneurs travel between the cities. In Minneapolis there is no lamp dimmer ordinance, such as has just gone into effect in St. Paul. In St. Paul there is no special law covering jitneys such as went into effect this week in Minneapolis. In the latter city automobiles may pass unloading street cars at a certain distance to the right. In St. Paul automobiles must stop when street cars are unloading passengers. The conflict of the laws causes a great amount of trouble and many arrests of Minneapolis people in St. Paul and St. Paul drivers in Minneapolis.

Ferro 8 Completes 300-Hr. Run

Higher Power at Finish than at Start—Run Practically Non-Stop

CLEVELAND, OHIO, July 8—A 300-hr. run on the test block has just been completed by the Ferro eight-cylinder motor made by the Ferro Foundry & Machine Co. While a few short pauses were made to change the oil and make a few adjustments, it was practically a non-stop run carried out solely for the information of the Ferro engineers and experimental department. An interesting feature is that at the conclusion of the run a higher maximum horsepower was shown than at the start.

The idea was to keep the motor turning over at 1500 r.p.m., at which speed it develops its rated S. A. E. horsepower, and twice during the run the throttle had to be closed a little to keep the speed down to the desired limit.

Commencing with a maximum test which showed 59 hp. the motor was then throttled to 34 hp. and at the finish of the run the maximum was a little over 61 hp. The test was made primarily with the idea that it would show up any weak spots in the motor, and as a matter of fact it did prove that one or two small fittings for which the Ferro company are not responsible were hardly up to standard, and a few replacements of such parts were made. As regards all the essentials of the motor, however, its condition was excellent in every way. For example the exhaust valves, one of which we have had the opportunity of examining, showed no indication of having been in use for more than a few hours, it not being pitted or scored at all. Such stops as took place were of only a few minutes' duration, giving the motor no opportunity for cooling off. Thus the test can be regarded only as satisfactory.

It should be remembered that this is the first long test of an eight of which any details have been made public.

—

Savannah to Register Automobiles

SAVANNAH, GA., July 8—Unless the State desires the city will not be a party to any appeal from the decision of Judge Charlton of the Supreme Court in the matter of the State automobile tax law and the city's automobile registration ordinance.

Now that the court has held the State law invalid the city's interest in the matter has ceased and it probably will take steps to pass a registration ordinance that is not based upon the State law. City Attorney John Rourke, Jr., will confer with Governor Harris and

Secretary of State Cook to learn what action the State proposes to take.

It had been the city's position all along that it could require the registration of automobiles and Judge Charlton upheld the contention. He declared the State law invalid because the method of apportioning the money to be derived from the special tax was not the proper one, and that the city ordinance was invalid because it was based upon an illegal law.

The probability is that the city will issue numbers and require them to be placed on all automobiles and motorcycles. The machines may be numbered according to the order of their registration. The purpose of Council in passing the ordinance was to provide a check on automobiles and motorcycles for the information of the police department.

—

Japan Poor Truck Market

AKRON, OHIO, July 8—That Japan is a poor market for motor trucks is indicated in a letter recently received by an American truck maker from the Tokio, Japan, branch of the B. F. Goodrich Co. The letter gives a list of Japanese merchants who have agencies for different makes of trucks.

—

Ford Buys Seven More Acres of Land

DETROIT, MICH., July 12—Henry Ford purchased seven more acres of land in the River Rouge district, where the new Ford plants will be located. The purchase price of the land was $20,000, it is said.

—

$50 for Accessory Theft

JOLIET, ILL., July 12—The Will county automobile club has offered a reward of $50 for the arrest and conviction of any person who steals accessories from automobiles.

—

Illinois Chauffeurs Examined

BLOOMINGTON, ILL., July 12—State examiners are now visiting the principal cities of Illinois, examining all chauffeurs eligible for licensing. A week is being spent in each city. All drivers who are under salary, are required to take the test.

—

Detroit S. A. E. Fund Increases

DETROIT, MICH., July 9—During June three new concerns have become contributors to the general fund which has been started by the Detroit section of the Society of Automobile Engineers to make it possible to maintain its local quarters. The new contributors are the Paige-Detroit Motor Car Co., which subscribed $100; the Willard Storage Battery Co. which contributed a similar amount and the Perfection Spring Co. which pledged $50. The fund totaled $2,450 July 1.

Breaks Chicago-to-N. Y. Record

—

E. C. Patterson Covers 1,015 Miles in 35 Hr., 43 Min. with Packard 3-38

NEW YORK CITY, July 13—From Chicago to New York in 35 hr. 43 min. was a record established to-day, when E. C. Patterson, Chicago motoring sportsman, and entrant of the Mercedes in which Ralph De Palma won the Indianapolis 500-mile race this year, finished the 1017.5-mile trip in a Packard 3-38, six-cylinder 4 by 5½, five-passenger touring car. This is elapsed time and shows an average of 28.48 m.p.h. In addition to maintaining this speed Patterson kept his motor running the entire time so that his performance was a non-motor-stop one. He carried with him three other passengers and pilots for the different stages so that the passenger load averaged five all of the time and it was six for short periods.

Delayed by Detours

The party left Chicago at 2.52 Monday morning and reached here 3.35 this Tuesday afternoon. The original schedule was to have brought the car here at 2.03 this afternoon, but there were delays due to detours, a long one at Elyria, Ohio, and another one near Buffalo. There was still further delay by a broken fan belt which had to be replaced at Albany, this being the only mechanical adjustment made during the trip. These delays, coupled with speed regulations entering Greater New York, held the car back. Stops consumed 1 hr. 29 min., leaving actual running time 34 hr. 14 min., which would give a running speed of 29.71 m.p.h.

Only Five Stops for Fuel

One year ago Mr. Patterson made a similar trip but with slower time, 41 hr. 37 min. Since then he has been working on arrangements for the present trip. He carried an additional tank carrying 20 gal. of gasoline in the tonneau and had only to make five stops for fuel on the road. Two speedometers were fitted, one showing 1017 miles and the other 1018. The Blue Book gives the route as 995, the added distance being for detours. Two horns were carried.

Roads Good All the Way

The route followed was through South Bend, Cleveland, Buffalo, Utica, Albany and Poughkeepsie. Roads were good all of the way. Mr. Patterson reports those in Indiana as good, Ohio as splendid, New York as excellent and Pennsylvania as good through Erie, etc. The weather was dry throughout. Night driving took place between Erie, Pa., and Canandaigua, N. Y.

Accompanying Mr. Patterson were: J. H. Cattell and J. E. Williams, official observers of the Chicago Automobile Club, and W. Gollan. Mr. Patterson drove 60 per cent of the distance. Two rear tires were changed.

—

Chevrolet Builds New Plant

FLINT, MICH., July 14—The Chevrolet Motor Co. of this city has recently acquired the balance of the capital stock of the Mason Motor Co., which has been furnishing the motors for the Chevrolet cars, and has started the erection of a new one-story motor manufacturing plant. The new building is 616 by 150 ft. and when completed, it is stated, the plant will be capable of an output of 1000 motors a day.

—

Anderson, Winton Engineer, Killed

CLEVELAND, OHIO, July 13—Harold B. Anderson, chief engineer of the Winton Co., was killed in a street car accident to-day in this city. Mr. Anderson had been with the Winton company since July, 1902. He was born April 1, 1878, and received his technical education in the Case School of Applied Science in this city. After graduation he was consulting engineer of the Van Wagner & Williams Co. for a period of one year, and was for 1½ years with the American Bicycle Co., and the International Motors Co., as mechanical engineer on gasoline car work. He went with the Winton company in July, 1902, being placed in charge of the engineering department not long afterwards. He leaves a widow.

—

New Dort Distributor in D. C.

WASHINGTON, D. C., July 13—The Miller Brothers Auto and Supply House, this city, has been appointed Dort distributor for the District of Columbia, Maryland and Virginia.

—

Disco Secures Large Contract

DETROIT, MICH., July 10—The Disco Electric Starter Co., Detroit, has the contract for supplying the Argo Motor Car Co. its starting and lighting systems. The Argo company has contracted for a minimum of 10,000 outfits, and the maximum is expected to exceed 20,000.

—

Ford J. M. Prices Reduced

NEW YORK CITY, July 10—Starting with the second week in July, all J. M. shock absorber branches all over the country will sell Ford J. M. Shock Absorbers at $15 per set or $8 per pair, instead of the previous prices of $25 per set or $15 per pair.

Eight New Ford Branches

Number Now Totals Forty-Three—Twenty-Six Assembling Plants

DETROIT, MICH., July 12—Eight new branches will be opened by the Ford Motor Co. Aug. 1. They will be located in Washington, D. C.; Council Bluffs, Iowa; Jacksonville, Fla.; Wichita, Kan.; Fort Worth, Tex.; Nashville, Tenn.; Syracuse and Utica, N. Y.

This will bring the total number of Ford branches in the United States to forty-three and the number of assembling plants to twenty-six. Some of the branches will probably ultimately become assembling plants, but for the present the Ford company does not intend to start new ones.

During the fiscal year ending July 31, the Ford company will have opened four branches and six assembling plants, while work was started on four additional assembling plants and additions started on two others.

—

Jackson-Church-Wilcox Additions Increase Production 50 Per Cent

SAGINAW, MICH., July 8—Additions to the plant of the Jackson-Church-Wilcox Co., manufacturers of steering gears, will enable this concern, it is claimed, to increase its production 50 per cent. One addition, consisting of a one-story building, 60 by 200 ft., with a saw-tooth roof, will provide more room for manufacturing purposes and for the stock room. The other addition, consisting of a two-story brick and steel open structure, 60 by 48 ft., will be used principally for a hardening department.

At the present time 200 men are employed, two shifts being used in some departments. The company's pay roll averages about $700 a day, it is claimed. During 1912 the company manufactured 27,000 steering gears; in 1913 the output was 57,000; the total was 67,000 in 1914, and for 1915 it is estimated that by the close of the business year, July 31, the output will show that a total of 100,000 steering gears have been made.

—

$600,000 Corp. to Build Tires

NEW YORK CITY, July 10—The Gryphon Rubber & Tire Corp., with a capital of $600,000, has been formed to manufacture pneumatic automobile tires of a foreign design with a 10,000-mile guarantee. A plant has been taken over in Mount Vernon, N. Y., 65 by 135 ft., and three stories in height, where, in about three months, it is stated, the company will produce 250 tires a day.

S. A. Cunningham, of 2 Wall Street; P. S. Jones, 5 Nassau Street, and L. Emdin, Deal, N. J., are the incorporators. Jones is the temporary president and Cunningham is treasurer.

The same design of tire has been manufactured extensively throughout Europe, the patentee being Isaac S. McGiehan of London, England. The American patent is No. 1,110,451, filed May 15, 1911. The tire is composed of a fabric carcass or foundation and a tread portion composed of layers of rubber-filled fabric of different widths formed into a crescent band, united thereto by an interposed film of softer rubber, all homogeneously vulcanized.

—

Firestone Adding Five New Buildings

AKRON, OHIO, July 8—The Firestone Tire & Rubber Co., this city, has placed contracts for the immediate extension of three of the big main wings, plus the doubling of a six-story separate factory building and the erection of a restaurant. This latter building will be three stories and a basement high, and will be about 150 ft. square with a floor space of about 90,000 sq. ft.

These new additions will add 302,000 sq. ft. of floor space to the present plant and will enable the company to nearly double its output.

The original Firestone factory was built in 1902. Here Firestone carriage tires were first made. Thirteen years ago Mr. Firestone and six others constituted the entire office force. To-day over 700 persons are required to handle the office work of the company.

—

Remy to Add 15,000 Sq. Ft. of Space

INDIANAPOLIS, IND., July 8.—The Remy Electric Co. of Anderson, Ind., will contract for two additional buildings at its local plant that will provide 15,000 more square feet of floor space. It was also definitely announced that the manufacturing departments of the Remy company will remain in Anderson. Recently it was decided to establish an experimental department plant at Detroit. Experimental work will start there soon. It has been definitely decided to do no manufacturing at Detroit. The plant at Anderson at this time is employing 1300 persons and with the additional capacity will employ 150 more.

—

To Occupy American Voiturette Plant

DETROIT, MICH., July 12—A metal refining company will occupy the plant formerly occupied by the American Voiturette Co. The Detroit Trust Co. sold the property and buildings for $45,000, which will go to the creditors of the former manufacturer of the Car-Nation and Keeton cars.

Paige Fairfield Six $100 Lower

Company Will Continue Model for 1916—Increased Production Brings Drop

DETROIT, MICH., July 8—The Paige-Detroit Motor Car Co. will continue for 1916 the Fairfield Six-48 which was placed on the market in January, 1915. The price of this seven-passenger car, the larger of the two Paige sixes, has been reduced to $1,295, or $100 less than this year's selling price.

The new price is said to have been made possible by increase in factory capacity and factory production, and the greater perfection of manufacturing methods and merchandising.

Briefly stated some of the principal features in the Fairfield Six-48 are 124-in. wheelbase, Continental L-head block motor, 3½ by 5¼, Bosch magneto, Gray & Davis starting and lighting system, cantilever springs, 34 by 4 tires.

—

Garage Association for Queens and Nassau Counties

BROOKLYN, N. Y., July 13—The Garage Owners' Association of Queens and Nassau Counties was formed last night at Disbrow Bros. Garage. The action followed the general recognition of certain abuses in the trade. It is planned to meet at an informal luncheon every Monday evening during the early stages of organization. The officers are: President, H. A. Aubinger, Jamaica; secretary, Edward Koster, Jamaica; treasurer, J. T. Callister, Greene County. Membership committee, Paul J. Stock, Owensboro Garage, Flushing; C. W. Smith, Great Neck; R. B. Sterling, Lynbrook; Fred C. Gehrke, Elmhurst; and C. C. Morigl, Ogden Garage, Central Park.

—

Mennonites Can Buy Cars

SABETHA, KAN., July 10—The prospect is that a few hundred automobiles, possibly reaching about 150 per cent of the families of the community, will be sold here soon. In other words, a community that has never bought automobiles is about to be in the market. The Amish church has modified its rule against automobiles and hundreds of Mennonite farmers are now buying machines.

—

Recent F. W. D. Changes

CLINTONVILLE, WIS., July 10—J. C. Turk, recently with the International Harvester Co., Philadelphia and New York and formerly in charge of sales for the International Pump Co. in South America and Cuba, has accepted a position of special representative in the

Eastern territory, with headquarters in Milwaukee, for the Four Wheel Drive Auto Co., Clintonville, Wis.

H. C. Gooding, recently in charge of the New York branch of the Corliss Carbon Co., and formerly manager of the Flanders Electric Vehicle Co., Canada, has become identified with the Four Wheel Drive company, as special representative in the middle west with headquarters at Chicago.

F. H. Burdette, recently with the Standard Motor Sales Co., Pittsburgh, Pa., and formerly district manager of the Neyberg company on the Pacific Coast, has joined the sales force of the Four Wheel company. Mr. Burdette will eventually devote his time to the Pacific Coast with headquarters at San Francisco.

Klaxon Wins Horn Suit

NEW YORK CITY, July 10—The Lovell-McConnell Mfg. Co. has won its suit against the Oriental Rubber & Supply Co., a Brooklyn dealer in accessories, Judge Chatfield having rendered an opinion holding the Hutchison patent No. 1,120,057 valid and infringed by electric horns sold by the Oriental concern. The court has issued an interlocutory injunction in favor of Lovell-McConnell and has appointed Joseph G. Cochran master to take an accounting and determine the extent of profits and damages to be paid by the Oriental Co.

The Hutchison patent, which figures in the suit, is one of eighteen new mechanical patents covering details of horn construction taken out by the Lovell-McConnell Mfg. Co., during the past year and covers a new construction having the drive shaft forming the axis of the electric motor at right angles to the plane of the diaphragm and slightly below the center. A face cam is used to vibrate the button at the center of the diaphragm. The suit was in the U. S. district court for the eastern district of New York.

Milwaukee Motor Rejects $37,500 Offer

MILWAUKEE, WIS., July 8—Creditors of the defunct Milwaukee Motor Co., Milwaukee, Wis., have rejected the offer of E. G. Miller and E. K. John, the principal stockholders, to pay $37,500 on condition that all claims be released. The First Trust Co., Milwaukee, trustee, filed a petition declaring it has a suit against Mr. Miller to recover $55,000, alleged to have been paid him out of the corporation's funds while the concern was insolvent, and a suit to recover $100,000 from Elise John alleged to be due under certain contracts existing between Miller, John and the corporation. The Imperial Automobile Co., Jackson, Mich., also has several suits against the defendants and defunct corporation on account of nondelivery of motors.

1916 Inter-State $150 Lower

No Changes Made in Car—Reduction on Roadster and Touring Models

MUNCIE, IND., July 9—The Inter-State Motor Co. has made a price reduction of $150 on its touring and roadster models which for 1915 sold at $1,000. The new price, $850, is the only change made for this season, the car being the same mechanically and as regards equipment.

The specifications of the Inter-State car include a four-cylinder Beaver motor with the cylinders cast in a block and with over-head valves. The cylinder dimensions are 3½ by 5 with a 2-in. carbon steel crankshaft carried on three main bearings, the front one having a length of 2¾ in., the center 2 in. and the rear 3⅜ in. The motor is oiled by a circulating splash system and is fitted with a 1-in. carbureter. Compactness has been made an object in the layout of the motor, the intake being on the left and the exhaust on the right. The electric starter is on the right, operating through a ring gear on the flywheel with which meshing is secured by a Bendix gear. Cooling is by the thermo-syphon system.

The clutch is a leather-faced cone on an aluminum spider and from it the drive is transmitted through the shaft to the gearbox which is in a unit with the floating axle. The gearset has nickel-steel gears and the drive is taken through a yoke construction. The rear springs are double shackled and the rear axle has a gear reduction of 4 to 1. It is a one-bearing design with 1-in. brakes. To insure a short turning radius a bottle-neck frame is employed.

The dash instruments are carried on a cowl board and the gasoline tank is under the cowl. The equipment includes a one-man top of mohair and full set of instruments and tools. The price, $850, is f.o.b. Muncie, and applies to either the touring car or the roadster.

Will Make Van Speedometers in Elgin Plant

AURORA, ILL., July 10—Details of arrangement, announced in brief in THE AUTOMOBILE last week, between the Van Sicklen Co., Aurora, and the Elgin National Watch Co., Elgin, whereby the latter will manufacture Van speedometers under the patents held by the former, now can be made public. The watch concern will take over the machinery, tools, equipment, raw material and material in the process of manufacture, owned by the Van Sicklen Co., and will manufacture the instruments, the Van Sicklen Co. handling the sales.

Some of the advantages gained are a larger production, unlimited facilities and unquestioned financial backing, the entire manufacturing and financial resources of the watch company being back of the Van Sicklen Co. in the production of speedometers and any other specialties it later may determine to market.

C. H. Hulbird, president; Guy V. Dickinson, general sales manager, and George E. Hunter, general superintendent of the Elgin National Watch Co., are stockholders in the Van Sicklen Co. The control, however, is vested in N. H. Van Sicklen, Sr.

The company is capitalized at $250,000, with all of it paid for in full at par, and there is none for sale. The general offices of the Van Sicklen Co. will be in Elgin after Aug. 1.

No Standard Truck Change

DETROIT, MICH., July 13—The Standard Motor Truck Co. states that no change in its organization has taken place.

Detroit Starter Capital Now $150,000

DETROIT, MICH., July 9—The Detroit Starter Co. has increased its capital stock from $20,000 to $150,000. This concern was started in October, 1914, and its business has been steadily increasing making an increase of capital necessary. At the present time the daily output averages thirty-five starters. This is to be increased to about 125 beginning August 1.

Robbins Co. to Move Plant

INDIANAPOLIS, IND., July 8—The Irvin Robbins Co., designer and manufacturer of automobile bodies, will move its factory to the old plant of the Irvin Manufacturing Co. at Morris and Division Streets. The new home has been thoroughly remodeled and is considered one of the model plants in Indianapolis. It is located on the Belt railroad, offering excellent facilities. In the old location the demand of outside manufacturers was so great that the Indianapolis market was neglected. The new plant was leased with the idea of supplying local automobile companies with bodies. E. Guy Robbins has been continued as president and general manager. W. O. Streller is purchasing agent and production manager. W. S. Eaton has been appointed mechanical engineer and J. A. Dougherty, sales manager.

Ford's Milwaukee Plant Begun

MILWAUKEE, WIS., July 10—The Ford Motor Co., Detroit, Mich., has awarded the general contract for the erection of

its new branch plant in Milwaukee, and work is now under way. It is planned to have the building ready for installation of equipment by November 1, so that operations may start November 15 or December 1. The Bossert contract is stated to be approximately $250,000. The factory will be located at Prospect Avenue, Kenilworth Place and the Northwestern tracks. A. W. L. Gilpin is Milwaukee manager.

—

Dividends Declared

Willys-Overland Co., Toledo, Ohio, quarterly 1½ per cent on the common stock, payable Aug. 1 to stockholders of record July 21.

Kelly-Springfield Tire Co., New York City, quarterly 1½ per cent on the common stock payable Aug. 2 to stockholders of record July 15.

—

Norwalk Stock Order Paid Up

MARTINSBURG, W. VA., July 9—At a meeting of the creditors of the bankrupt Norwalk Motor Car Co., held at the office of Referee in Bankruptcy W. H. Thomas, the referee entered an order directing that the claims for labor, filed against the company by the workmen and others and amounting to approximately $1,150, be paid out of the assets. It was also ordered that all deferred payments on the stock of the company be collected immediately.

There will be a meeting of the creditors on July 19 at which time the report of Receiver C. G. Smith will be taken up for consideration. At that time it will be decided by Referee Thomas whether the claims filed when Mr. Smith was State receiver can be filed with the bankruptcy claims.

Security Prices Are Normal

—

Prices Gain on Saturday After Publication of German Reply to Note

NEW YORK CITY, July 12—Security prices at the close on Saturday showed few important changes, the gains or losses hovering between a fraction to 3 points.

The publication of the German reply to President Wilson's note in Saturday's papers had a favorable influence on the initial trading, gains ranging from fractions to 3 points, with most of the buying from the speculative interests.

Automobile and tire issues remained active throughout the week with a few small changes. International preferred went up 3 points, the largest gain for the week. Its common went down ½ point. Chalmers preferred went up 1 point while its common declined 1 point.

Few changes were recorded in the tire issues. Goodrich common dropped 2 points and the preferred rose ½ point. Goodyear common rose 1 point; Kelly-Springfield common rose 2 points, and U. S. Rubber common and preferred rose and dropped ½ point, respectively.

The Detroit issues were a little more active last week, nearly every one of them showing changes. Continental common went up 10 points, the same stock having gone up 5 points.

—

Stewart-Warner Extra Dividend

NEW YORK CITY, July 10—The Stewart-Warner Speedometer Co., it is said, will increase the common dividend rate or declare an extra disbursement next fall. The stock has paid 6 per cent per annum since the organization. Profits this year are running well ahead of those of the corresponding period of 1914, and indications are that in the year to December 31 next the company will earn between 12 per cent and 15 per cent on the $10,000,000 common stock.

—

Michigan Buggy Plant Sold—Purchaser to Build $600 Car

KALAMAZOO, MICH., July 6—Part of the plant of the old Michigan Buggy Co. has been purchased by representatives of the States Motor Car Co. of Toledo, Ohio. The consideration is stated to be $60,000. The States company will manufacture a four-cylinder roadster and touring car, to be known as the Greyhound, and which is to be listed, it is stated, at $600. Those interested in the Toledo concern are W. D. Smith, Toledo, Ohio; Dr. F. C. Bonine, Niles, Ohio; James H. Johnson, South Haven, Mich. It is claimed that pending the time required to put the local plant into operation a Chicago manufacturing concern will turn out the first lot of the new car.

—

Ross Heads Eureka Starter Co.

COLUMBUS, OHIO, July 10—The Eureka Mechanical Starter Co., which was incorporated some time ago with a capital of $30,000 has been organized by the selection of W. A. Ross, president; J. E. Matthews, vice-president and C. E. Bonebrake, secretary. The company holds patents on a mechanical starting device which is said to be out of the ordinary. The device will be manufactured under the contract by other concerns.

Erskine Studebaker President

Fish Chairman of Board of Directors Who Are Now Divided in Five Groups

NEW YORK CITY, July 8—At a meeting of the directors of the Studebaker Corp., to-day, F. S. Fish was chosen chairman of the board, succeeding J. M. Studebaker. A. R. Erskine, who was vice-president and treasurer, was elected president. C. C. Hanch was chosen treasurer. Mr. Studebaker, the surviving one of the five Studebaker brothers, still stays at the head of the corporation as honorary president, having resigned as chairman of the board of directors.

At a special meeting held yesterday in Jersey City, N. J., the stockholders of the company adopted an amendment to the certificate of incorporation for the classification of directors in groups. The term of office of the board members was arranged afterward in this way: J. M. Studebaker, G. M. Studebaker and J. R. Turner to retire in 1916; E. R. Benson, W. R. Innis and D. M. F. Weeks in 1917; Herbert Lehman, N. J. Riley and A. B. Hepburn in 1918; F. P. Delafield, Philip Lehman and J. G. Heaslet in 1919, and F. S. Fish, A. R. Erskine and Henry Goldman in 1920.

The changes were in line with plans made in 1913 for increasing the corporation's productions and reducing manufacturing costs. At that time Mr. Erskine went over to the Studebaker organization from the Underwood Typewriter Co., of which he had been general manager.

War orders received thus far by the company amount to more than $20,000,000, the major part of which has been executed. These orders were received from the English, French, Russian, German and Austrian governments and included automobiles and harness.

The company is free from bank debt, its only obligation being approximately $3,000,000 of notes and the company has $7,000,000 in deposit in banks. The earnings on the stock at present are at a rate of considerably more than 20 per cent per annum.

—

Ross Eight Builder Changes Name

DETROIT, MICH., July 10—The Ross & Young Machine Co. has been succeeded by the Ross Automobile Co., which will continue to build the ROSS eight-cylinder car which was announced last January. The new company has been incorporated, its capital stock being $300,000.

—

Steel Prices Higher

NEW YORK CITY, July 13—The prices of Bessemer and Open-Hearth steel were higher last week on account of large domestic and foreign orders. Bessemer fluctuated throughout the week, reaching $20 a ton on Wednesday, dropping the next day to $19.50, and holding at that price until the close on Monday, a 50-cent rise. Open-Hearth had a gradual rise, closing at $20.50 per ton, just $1 higher than Tuesday's price.

The rest of the metals showed a declining tendency. Lead went down 5 cents a 100 lb. and both electrolytic and Lake coppers dropped ½ cent and 1 cent, respectively. Aluminum was steady with a fair demand, holding at 31 cents a pound throughout the week. Both coppers were dull, with domestic consumers remaining out of the market. The exports were light. Tin was dull and lower, quoting at the close at $38.50, a 28-cent drop for a 100 lb.

Only one change occurred in the oils and lubricants markets, that being a 7-cent drop on refined rapeseed oil, due to a falling off in demand. Cottonseed oil held steady throughout the week, closing at $6.03 a barrel.

No new features of importance developed in the crude rubber market. Fine Up-river Para held strong at 63 cents.

Texas Crops Increase Orders

Dealers Report Large Sales—Farmers Are Prosperous—Big Cotton Yield Assured

AUSTIN, TEX., July 10—It is stated by automobile dealers of Austin and other cities and towns of the State that the promising crop conditions are reflected in the large increase of orders for cars which were recorded during the thirty days ending June 8, as compared with the previous thirty days. In the wheat districts of north Texas and in the Panhandle the sale of cars is particularly heavy at this time. The wheat and oats crops have been harvested and the bulk of the grain sold at good prices. The farmers are enjoying an unusual degree of prosperity and many of them are investing part of their surplus funds in automobiles. The prosperous condition of the farmers makes business good in the towns and the automobile sales are very satisfactory at this time in the urban communities as well as in the country localities. Another big yield of cotton for Texas is now practically assured. Notwithstanding the decrease of acreage it will not be surprising if the total production of the staple this year is not in excess of 4,000,000 bales. Everything points favorably to unprecedented activity in the various lines of the automobile trade in this State during the late summer and fall months.

—

Dividend Action on General Motors Stock Expected

NEW YORK CITY, July 8—The directors of the General Motors Co. will meet next month, and it is expected that at this session action will be taken on the matter of dividends on the common stock.

The company's fiscal year ends July 31, and it is estimated that surplus for the common stock will be well over $50 a share. Earnings on the common in the 1914 fiscal period amounted to 37.6 per cent, and the current fiscal year will be the third successive one in which the company has earned a surplus over 37 per cent on the common. The company has paid no dividends on the common stock as yet.

There is outstanding $14,895,200 preferred, and $16,501,783 common stock. It is stated that in addition to the common stock being placed on a cash dividend basis next month a stock dividend also will be declared.

Wilson Body Buys Building

DETROIT, MICH., July 12—The C. R. Wilson Body Co. has purchased a brick building, 25 by 100 ft., located at 494 Clay Avenue.

2½-Mile Speedway for Pittsburgh

Association Formed with $1,100,000 Capital—Three Sites Under Option

PITTSBURGH, PA., July 12—Pittsburgh is going to have a speedway. The moving spirit therein is J. Numa Jordy, who hails from Florida and is general manager and fiscal agent of the Pittsburgh Speedway Association. The officers of the association, which is going ahead full speed already, are: President, F. J. Kress, who by the way is also president of the F. J. Kress Box Co., a large manufacturing concern, and also of the Pittsburgh Commercial Club; vice-presidents, J. Howard Fry, vice-president of the H. C. Fry Cut Glass Co., Rochester, Pa., and R. D. Ward, general manager of the Ward Baking Co., New York and Pittsburgh; treasurer, Joseph R. Robinson, president of the Braddock Laundry Co. These with Joseph B. Callahan, western Pennsylvania manager of the Security Mutual Life Insurance Co.; Dick Briney, president of the Mutual Laundry Co.; Joseph J. Carr, a well-known real estate man; W. J. Phillips, president of the Phillips & McLaren Co., and Dr. Adolph L. Lewin of the Pennsylvania Savings Bank and the Pittsburgh Central Board of Education, constitute the board of directors.

The Pittsburgh Speedway Assn. has been incorporated under Delaware laws with a capital of $1,100,000, non-assessable. The first 1000 memberships will be sold at the rate of $250 each, which gives the holder not only a life membership in the association but twenty-five shares of stock, paid up, and also all privileges of the Speedway association and the Speedway Park Club. Of this sum $62.50 is to be paid when the application is made and $187.50 in three equal amounts without interest at two, four and six months. The membership certificates are transferable one year after date on approval of the board of directors. About 410 of these first 1000 memberships have already been sold.

The association has secured for engineers Richard Irvin & Co. and the Hunting-Davis Co., both of Pittsburgh. As director of its amateur contests the board has secured Oscar C. Seikel, athletic director of the Pittsburgh Athletic Association.

The speedway as planned will be 2½ miles long and from 70 to 90 ft. wide with a graduated curve from 3 deg. in the straightaway to 19 deg. at the turns. In the infield, which will contain 160 acres, there will be an eighteen-hole golf course, and tennis courts. The grandstand will have a seating capacity of 150,000 people. There will also be a polo field, gun club and bridle path of 56 acres.

The association has three sites under option. All of these are within a radius of 14 miles of Pittsburgh, and any of them will be easily reached by railroad, trolley car and macadam roads. A definite decision as to site will be made before July 20.

The capital of the association is $1,100,000 in shares of $10 each. The estimated cost of the speedway ground, park and building is about $900,000.

—

Detroit Electric's 2065-Mile Run Costs $29

DETROIT, MICH., July 9—The Anderson Electric Car Co., has given out figures on the cost of operating its electric brougham during a 26-day test run in June when the car made daily runs averaging 79.4 miles in the vicinity of Detroit. Total cost for the run which aggregated 2065 miles was $29, made up as follows:

Electric current for battery	$26.56
Flushing battery eight times	1.50
Filling grease cups three times	.75
Tightening steering tie rod	.19
Total	$29.00

The car used for the test was a model 53, weighing 3962 lb., having a 42-cell 15 W T X lead battery and being fitted with Silvertown cord tires 34 by 4½. The average number of passengers carried on each run was five, the minimum was four and the maximum was six. The average weight of the passengers was 740 lb., the maximum was 900 lb. and the minimum 550 lb. An average speed of 18 miles per hour was maintained during twenty runs, the maximum speed was 22 miles per hour and the minimum speed was 17 miles per hour.

—

Readville 1-Mile Record Broken

BOSTON, MASS., July 10—In the postponed automobile races held here to-day originally planned for the holiday last Monday, Boston and New York drivers fought out the events with honors even at the finish. There were about 1500 present. A new record for Readville track of 55 4/5 sec. was made by Vail in a Mulford special. Matty Matthews of New York had charge of the races. The summary:

One mile time trials—Won by Vail, Mulford Special, 55 4/5 sec.; Le Cain, Chevrolet, 58 sec., second; Dickinson, Stutz, 59 sec., third.

Ten miles, non-stock—Won by Vail, Mulford Special; Jessup, Chevrolet, second; Jackson, Correjo, third. Time 9 min. 50 sec.

Twenty-five miles, non-stock—Won by Le Cain, Chevrolet; Dickinson, Stutz, second; Murchurio, Stutz, third. Time 26 min. 22 sec.

Ten miles, handicap—Won by Dickinson, Stutz, 33 sec.; Jessup, Chevrolet, 22 sec., second; Werner, Otto, 2 min., third. Time 12 min., 30 sec.

Australian pursuit race—Won by Dickinson, Stutz; Le Cain, Chevrolet, second. No time taken.

DePalma to Campaign Stutz Racer

Leases 300-Inch Car—Harry Stutz to Withdraw from Active Racing?

CHICAGO, ILL., July 12—Ralph De Palma has leased the 300-inch Stutz, driven by Howard Wilcox at Indianapolis and has entered the car in the Elgin road races of August 20 and 21. On top of this report comes the rumor that Harry Stutz will withdraw from active racing. Stutz is at present on a fishing trip in the Wisconsin woods, so this cannot be confirmed. Henry Campbell, treasurer of the company, when interviewed, said that the Stutz company had been negotiating with DePalma.

"We are not actually quitting the game. We are endeavoring to campaign them. The cars will belong to DePalma but we will furnish all parts and repairs free of charge and he will retain all prize money. We have the same arrangement with Earl Cooper and hope to close on this basis with DePalma."

When asked if the DePalma arrangement would mark the passing of the Stutz company from actual racing, Campbell evaded the question by saying that the Stutz name would receive the same publicity with DePalma as a team manager as it would under the factory directorship. Campbell refused to make a positive statement on the condition of affairs until Harry Stutz returned to Indianapolis. Stutz has been an ardent supporter of racing since 1911. Cooper has one of the three Stutz cars on the Pacific Coast; DePalma has closed for the other and the third is in Indianapolis.

DePalma has announced that he would campaign the Stutz for the remainder of the 1915 season in addition to the two Mercedes that he has had in his stable for the past year. Last Sunday and Monday he entered the car at the Saginaw, Mich., race meet, where he captured six races on the ½-mile dirt track. He announced that he would drive one of the Mercedes at Elgin and that Caleb Bragg would be at the wheel of the other, but did not name a driver for the Stutz.

—

DePalma's Stutz First Elgin Entry

CHICAGO, ILL., July 8—The nomination of DePalma's Stutz is the first entry received for the Elgin classics. De Palma will withhold the Mercedes entries until later in the month. E. C. Patterson of Chicago, who has backed the Italian's Mercedes for the past two years, signed the entry blank for the Stutz. It is understood that he and DePalma will stand all the expenses of putting the car in shape for the Kane County events.

Maxwell Withdraws from Racing

No Racing Payroll After August 1—Not Due to Death of Driver Carlson

DETROIT, MICH., July 12—The Maxwell Motor Co., Inc., has withdrawn from speedway racing and is now winding up its racing affairs so that there will be no racing pay roll after Aug. 1. The various Maxwell racing cars have been shipped here where they will be overhauled, but no intimation is made as to their disposal, other than that they will not be raced by the Maxwell company or any of its subsidiaries. It is claimed that this withdrawal of the Maxwell company is not due to the death of Carlson and his mechanic in the recent Omaha meet, but to certain dissatisfaction they claim in connection with Maxwell races.

—

Another Race on Omaha Speedway

OMAHA, NEB., July 12—The directorate of the Omaha speedway is planning to hold another contest on the 1¼-mile track in October, ten days or two weeks after the inaugural event on the Sheepshead Bay track October 2. The Omaha race will be held during the week of the Ak Sar Ben festival, when the Nebraska metropolis is thronged with visitors. The distance and prize money have not been decided upon as yet. The owners have decided to make two changes in the course. The guard rails will be reinforced by the use of hickory timber and the safety apron at the inside edge of the track will be extended 20 ft. further.

—

Chicago's 350-Mile Race to Be October 16

CHICAGO, ILL., July 13—*Special Telegram*—At the request of Everard Thompson, manager of the Sheepshead Bay speedway, the management of the Chicago speedway has changed the date of its fall race from Sept. 18 to Oct. 16. Thompson feared that if the Chicago contest was held prior to the opening of Gotham's track, Oct. 2, he might lose some of his entries.

The Chicago race will be the same distance as that in New York, 350 miles instead of 300 miles as formerly agreed upon, in order that the drivers will have an opportunity here to shatter New York records made at Sheepshead Bay.

—

Chicago Invitation Event Aug. 8

CHICAGO, ILL., July 9—In addition to scheduling a fall race of 300 miles for Oct. 16, the owners of the Chicago speedway are planning to hold an invitation event on the wooden bowl next month probably Sunday, Aug. 8. The contest will be 100 miles in length, and the following drivers will be asked to enter: Dario Resta, winner of the Vanderbilt Cup, Grand Prize and Chicago race; Ralph DePalma, this year's victor at Indianapolis; Barney Oldfield, and Earl Cooper.

—

Increase Elgin Prize Money

CHICAGO, ILL., July 13—*Special Telegram*—Promoters of the Elgin road races have decided to increase the prize money for the annual classics, the purse for each of which totals $3,000. They will take a gambler's chance on the endurance of the cars and each day will give $100 to each driver completing 100 miles and $200 to each driver finishing 200 miles, provided the recipient is not eligible to participate in the split of the regular prize money.

—

$500,000 Speedway for New Orleans

NEW ORLEANS, LA., July 9—An automobile speedway and equipment to cost about $500,000 will be constructed in time for a long distance race in February, 1916, the Saturday before Mardi Gras. It was declared that the Mardi Gras race would be made an annual event.

H. C. Moore and S. H. Lindsay of Chicago, are representing the promoters. They have obtained an option on an extensive tract of land in the outskirts of the city.

—

No Uniontown Hill Climb in 1916

HARRISBURG, PA., July 9—State Highway Commissioner Cunningham has issued notice that no road races or hill climbing contests will be allowed on the state highways. The recent hill climb at Uniontown caused such damage to the road, it is said, that the commissioner asked the attorney-general whether it was within his power to forbid such exhibitions in the future. The attorney-general said that it was.

—

Duesenbergs for Twin Cities

MINNEAPOLIS, MINN., July 10—Fred Duesenberg of St. Paul, entered the first three cars for the 500-mile race on the Twin-City speedway here Sept. 4. Two of the entries are new sixteen-valve motors, 299 cu. in. cylinder capacity.

—

Porporato to Drive F-R-P Car

NEW YORK CITY, July 8—Jean Porporato is going to drive an American car, the F-R-P. Mr. Porter will remain general manager of the team and Porporato will hold the title of manager.

Burman Stars at Burlington

Averages 47.06 M.P.H. in First 100-Mile Race on ½-Mile Dirt Track

BURLINGTON, IOWA, July 9—In the first 100-mile race held on a banked ½-mile dirt track under the A. A. A. sanction, Burman, driving his Peugeot, captured first money this afternoon, covering the distance in 2 hr. 7 min., 29.66 sec., averaging 47.06 m.p.h. for the century. At the Kalamazoo 100-mile race last September, Burman made the distance in 1:34:29 2-5, an average of 63.6 m.p.h. O'Donnell's Duesenberg made the distance at Galesburg, June 9, in 1:36 or at 62.5 m.p.h.

The three Duesenbergs, driven by Chandler, O'Donnell and Alley, ran second, third and fourth and annexed $1,350, the major portion of the $2,550 prize money. O'Donnell also won three purses of $100 each for leading at 25½ and 75 miles.

O'Donnell was more than a serious contender at the crack of the starter's pistol; he and Alley jumped to the front and at the completion of 25 miles had a commanding lead over their rivals. O'Donnell kept increasing this advantage and was four laps ahead of Burman when he was forced to stop at his pits after covering 86 miles because of a cracked hub and a broken bearing. This stop lost the race for O'Donnell while he was repairing his car. Burman made up the lost ground and passed him, although he had to make a tire change, while the Duesenberg was at the pits. Burman finished almost 7 min. ahead of Chandler, who captured second place from O'Donnell by the narrow margin of 22 sec. Seconds only separated O'Donnell and Alley, making the race one of the most spectacular held on a dirt track this season.

Three other cars started, Joe Cooper's Sebring; Brown's Du Chesneau and Dall's Buick; the Sebring was put out of commission with a water-flooded carbureter when the car went through a fence and plunged into a pond on its ninety-eighth lap. The Du Chesneau made 199 circuits of the track but did not cross the finishing line. The Buick was distanced. The summary:

Car	Driver	Time
Peugeot	Burman	2:07:29.66
Duesenberg	Chandler	2:14:14.23
Duesenberg	O'Donnell	2:14:36.80
Duesenberg	Alley	2:14:51.19

O'Donnell's time for the intermediate distance was as follows:

Distance	Time
25	29:10.31
50	1:16.91
75	1:30:47.18

To Determine Status of Jitney

Indiana Trolley Co. Wants P. S. C. Control—Developments in Other Sections

INDIANAPOLIS, IND., July 13—*Special Telegram*—The Terre Haute, Indianapolis and Eastern Traction Co. to-day filed with the Public Service Commission a long petition asking for an order from the Commission "declaring persons owning, operating, managing and controlling jitney buses to be public utilities and subject to the authority of the Public Service Commission."

The Commission has set July 22 as a date for a hearing on the petition. The scene of the present battle is laid in Terre Haute, although the petition recites that the T. H., I. and E. operates in other cities of the State. That the new method of passenger traffic in the cities is a "substantial and destructive competition of a new type" is admitted by the petition of the Traction company. Senator Al. Zearing at the last session of the Indiana Assembly introduced a bill that sought to put the jitney buses all over the State under the control and regulation of the Public Service Commission. This bill was defeated in the Senate and never reached the House of Representatives for action.

—

Want New York Jitneys Regulated

NEW YORK CITY, July 14—The first meeting of the Transportation Committee of the Safety First Federation was held yesterday in the Craftsman Building, on Thirty-ninth Street. The speakers were in favor of regulating the jitney by law and holding their owners responsible for accidents. Opinion was divided, however, as to whether the jitneys would be permanent or not.

—

Baltimore Jitneys to Fight City Ordinance

BALTIMORE, MD., July 10—A unique turn in the plan to regulate jitney buses in this city came to-day. The City Council at a special session passed an ordinance regulating the machines after striking taxicabs and other passenger-carrying motor vehicles, with the exception of the jitney, out of the proposed law. William Curran, a candidate for State's Attorney, who represents a number of the jitney owners, said to-day that if the buses do not follow a regular route they are bound to come under the head of passenger-carrying vehicles and no longer can they be considered under the heading of jitneys.

It is planned that as soon as the law on jitneys goes into effect, which will be week after next, the jitney people will discontinue to run over regular routes.

It also is planned to take the fight into the courts and have it settled. The jitney men are said to have strong backing and they are determined to fight. They claim they are discriminated against.

The ordinance compels each bus to pay a tax of $25 per seat per year.

The measure also contains the following provisions:

No person under twenty-one years of age will be permitted to operate jitney, only one person is to ride on the seat with the chauffeur, buses will carry only seating capacity, no one is to ride on the running boards or steps, speed limit of 15 miles an hour and no soliciting permitted, licenses must be obtained from the collector of water rents and licenses and upon these must be stated the time the license is to run and the seating capacity of the vehicle. This license must be posted in the bus. A fine of from $10 to $100 is provided for violation of the law. The money taken in by the city is to go to the account for repairing streets.

—

No Garages in Baltimore Residential Section

BALTIMORE, MD., July 12—No public garages are to be erected in the purely residential sections of Baltimore. This is the stand taken by Mayor Preston and he has already turned down some applicants who wanted to build garages in these sections.

—

Reo Changes in Los Angeles

LOS ANGELES, CAL., July 9—One of the most important moves of the year in California automobile affairs is the taking over of the California agency for the Reo line by Earle C. Anthony, Inc. The Anthony organization now has the Packard and Chalmers and with the Reo and the state-wide service system which Anthony now maintains, the organization becomes one of the largest automobile agencies in the country.

—

12 Tons Baltimore Limit

BALTIMORE, MD., July 10—An ordinance prohibiting motor trucks weighing over 12 tons with solid rubber tires to cross any of the bridges in Baltimore has been passed. The measure also provides that to pass over the city streets any truck weighing more than 14 tons, combined weight of vehicle and load, must do so under a special permit issued by the city engineer.

—

To Regulate Columbus Garages

COLUMBUS, OHIO, July 9—Two ordinances have been introduced in the city council for the regulation of garages and gasoline filling stations. The ordinances were drawn by the Columbus Chamber of Commerce after an investigation of a special committee.

One ordinance provides that it shall be illegal to construct, maintain or operate a garage located within 187½ ft. of the street on any lot, where three-fourths of the buildings on either side to a distance of 500 ft. are exclusively dwellings, without the consent of two-thirds of the property owners within such frontage of 1000 ft.

The second ordinance is directed against both old and new filling stations and contains about the same provisions as in the ordinance affecting garages.

—

Southern Pacific Railroad Adopts Master Carbureter

LOS ANGELES, CAL., June 23—The Southern Pacific Co. has adopted the Master carbureter as standard equipment for all its automobile coaches. There are thirty-five of these motor coaches on the Pacific Coast, eighteen out of Sacramento, eight out of Los Angeles, seven out of Portland and two out of Stockton. The cars have six-cylinder power plants with a bore and stroke 10 by 12, each motor using two carbureters.

—

Jitney Ordinance for Minneapolis

MINNEAPOLIS, MINN., July 10—The Minneapolis City Council has passed a jitney ordinance providing for a $15 annual license, conditional on the filing of an approved bond for $10,000 maximum liability. Cars must operate to ends of routes indicated by signs, may carry two more passengers in excess of regular seating capacity, and provision is made for police inspection as to competency of drivers.

—

Indianapolis Controls Pedestrians

INDIANAPOLIS, IND., July 10—The new traffic rules regulating the parking of automobiles in downtown streets and setting out that pedestrians must obey the signals of traffic policemen in the same manner as vehicles are required to do, went into effect here July 10. Hereafter pedestrians, when crossing streets downtown, will be required to listen for and obey the signals of the traffic officers. Restricted districts have been set aside for parking spaces.

—

$500 and Jail for Drink

MILWAUKEE, WIS., July 10—A stringent law relating to the operation of automobiles by intoxicated persons has been passed by the Wisconsin Legislature of 1915 and is now in effect. The statute places a penalty of $10 to $200 fine for first offense and a fine of $50 to $500 or a jail term of not less than 60 days or both, for second and subsequent offenses.

Factory Miscellany

Western Battery Moves—The Western Storage Battery Co., Chicago, Ill., has moved to Portage, Wis.

To Make Wheel Rests—Eborn Brothers, Orland, Cal., are building a factory to manufacture automobile wheel rests.

Maccar to Build—The Maccar Truck Manufacturing Co., Scranton, Pa., is preparing plans for an addition to its plant for the manufacture of trucks.

Quality Tire to Add—The Quality Tire & Rubber Co. has increased its capital stock and will enlarge its plant at Hartville, Ohio, in the near future.

Covert to Build—The Covert Motor Vehicle Co., Lockport, N. Y., has let contract for a three-story and basement addition, 46 by 92 ft., to its factory.

Pequannock Rubber Builds—The Pequannock Rubber Co., Butler, N. J., will build a three-story, 47 by 180 ft. and a one-story, 40 by 75 ft. factory to cost $50,000.

To Make Accessories—The National Service Corp., Hummelstown, Pa., has purchased a canning factory and will convert it into a manufactory for automobile supplies.

To Mfr. Four-Wheel-Drive Truck—N. C. Miller & Son, Dodgeville, Wis., are planning to engage in the manufacture of a new type of four-wheel drive for automobiles and motor trucks.

To Make Truck Bodies—The Hercules Buggy Co., Evansville, Ind., will manufacture a new line of truck bodies and employment will be given to 150 additional men. The men will be put to work in two weeks.

To Make Wheel Builder—The Hinkle Mfg. Co. has been formed in Xenia, Ohio, to manufacture automobile wheel builders. C. R. Hinkle is president. Stock is now being sold and within a short time the company will take up the active manufacture of the new machine.

To Make Trailers—The Erie Trailer Mfg. Co., Erie, has established a plant at Twelfth and Liberty Streets for the manufacture of trailers to be attached to automobiles. These will be made in different capacities for various hauling purposes. In addition a line will be made for attachment to jitney buses for carrying passengers.

Dunlap Parts Plant For Sale—H. C. Park, receiver for the Dunlap Mfg. Co., Columbus, Ohio, formerly manufacturer of automobile parts, has asked the court for instructions as to the disposal of the plant, located on Parsons Avenue. The property was appraised at $42,505 and an offer of $40,000 for the plant and fixtures has been received.

To Make Tops—The Wisconsin Auto Top Co. has been incorporated at Racine, Wis., to succeed to the partnership business conducted by the heirs of the late C. E. McAvoy. The new company has a capital stock of $15,000 and the corporators are Alice, Edward and Charles McAvoy. The plant manufactures tops, seat covers and other trimming goods and devices for the motor car trade.

To Occupy S. G. V. Plant—The American Die & Tool Co. will occupy the building formerly known as the S. G. V. plant in Reading, Pa. The main office of the company will remain at its present location, Second and Buttonwood Streets, at which plant it will continue to manufacture axles and miscellaneous bevel-gear work. The new plant will manufacture automobile transmissions and miscellaneous spur-gear work.

To Make Universal Joints—A universal joint for automobiles is one of the new products which the American Rotary Valve Co., Anderson, Ind., has adopted, and preparations are being made at the plant to turn out about 100 joints a day by Oct. 1 and 200 per day by Dec. 1. W. T. Hensley, formerly with the Westinghouse company of East Pittsburgh, Pa., has joined the company as consulting engineer.

J. I. C. Co. Buys Plant—The plant and business of the Perfection Road Machinery Co., Galion, Ohio, has been purchased by the J. I. Case Threshing Machine Co., Racine, Wis., which has built road construction equipment for several years. The Perfection plant manufactures graders, plows, drags and other machines. No details are available as to the disposition the Case company will make of the Galion plant, but it is presumed these works will not be disturbed and will be operated as a branch of the immense Case organization.

Hupp Clubhouse Opened—The Hupp Motor Car Co., Detroit, Mich., has opened a clubhouse adjacent to its plant for the benefit of its employees. Pending the completion of its new lunchroom in the factory a restaurant will be operated in the clubhouse, which president J. Walter Drake wishes to make a social center. A large lawn next to the clubhouse is being fitted to permit all kinds of games. Office manager F. B. Sides is in charge of the clubhouse, which after it is in running order is to be managed by the employees themselves but with the financial assistance of the Hupp company.

Goodyear Installs Hydraulic Presses—The Goodyear Tire & Rubber Co., Akron, Ohio, has completed the installation of hydraulic presses in its various branches throughout the country, for the purpose of equipping motor trucks with the pressed-on S V truck tire.

The Automobile Calendar

The Week in the Industry

Gilson Puritan Sales Assistant—A. Gilson has been appointed as assistant to service sales manager, E. W. Hawley, of the Puritan Machine Co., Detroit.

Mason Heads Indianapolis Garford—The Garford Motor Truck Co., Lima, Ohio, has opened permanent headquarters in Indianapolis. W. R. Mason has been placed in charge of the state distribution. A service station is also maintained.

Frisbie Empire Rep. Now—Joe Frisbie, Indianapolis, Ind., manager of the Empire Tire & Rubber Co., has been promoted to special representative and will assume his new duties at once. J. E. Bright of Chicago, will succeed Frisbie as local manager.

Crawford Resigns from Case—J. F. Crawford, master mechanic of the automobile department of the J. I. Case Threshing Machine Co., Racine, Wis., in charge of design, has resigned to become associated with the Curtiss Aeroplane Co., Hammondsport, N. Y., as chief motor designer.

—

Garage

New Kansas City Garage—C. B. Traves has opened a new garage at 3320-22 South Main Street, Kansas City.

Genemotor in Baltimore—E. I. Rosenfeld & Co., Inc., 8 South Howard Street, Baltimore, have become the local distributors of the Genemotor, the starter for the Ford cars.

Havana Garage Completed—The new garage building of Coppel & Harsman in Havana, Ill., is completed and the firm moved in this week. Franklin Harsman, formerly in business alone, has taken Lloyd Coppel into partnership, commencing with July 1. This firm has the agency for the Ford and Overland cars and handles a large amount of repair work from Mason county.

Louisville's New Retail Supply House—The Highland Auto Supply Co. will open a wholesale and retail automobile supply house at 813 South Third Street, Louisville, Ky. Salesmen will travel five states. The company also will handle the local wholesale business of the Highland Body Mfg. Co. of Cincinnati, Ohio, which formerly maintained a branch at 728 South Fourth Street. The company is the distributor for Rex plugs, Manzell motor-driven pumps; State agent for Wheeler & Schebler carbureter, and will feature a large line of babbitt repair parts.

Motor Men in New Roles

Levi Goes to Atlanta—J. E. Levi, late with the Premier Motor Manufacturing Co., has been appointed Dixie factory representative for the King eight, with headquarters at Atlanta.

Knapp Makes Texas Change—Wm. Knapp, formerly manager of the Hudson-Davis Co., Mesquite, Tex., has succeeded R. M. Ellis as manager of the Hudson-Davis agency in Arlington, Tex.

Howard Now a Dealer—C. E. Christian has sold the Hupmobile Agency at Kansas City to W. C. Howard. Mr. Howard was formerly assistant sales manager of the Hupmobile factories.

Gaugh Heads Dayton Tire Branch—A distributing plant for the Dayton Tire Co. has been established at 1945 Grand Avenue, Kansas City, Mo. This branch house is in charge of Mort Gaugh.

Carr and Morford Join Herff-Brooks—The Herff-Brooks Corp. has appointed J. G. Carr and Paul Morford district sales managers. Mr. Carr has been with the National Co. and Mr. Morford with the Regal Co.

Willis, Chalmers Assistant — F. B. Willis, has been appointed assistant sales manager of the Chalmers Motor Co., Detroit, Mich. He was eastern district manager of the Lozier Motor Co., also district sales manager for the Chalmers company.

Durning Makes Change—W. J. Durning, formerly connected with the Goodrich Rubber Co., Akron, Ohio, has opened a vulcanizing and tire repair shop at 138 North Third Street, Louisville, Ky. He contemplates taking the agency for a pleasure car.

Moore Rejoins King—I. B. Moore, late of the Empire Motor Car Co., Indianapolis, Ind., formerly with the King Motor Car Co., Detroit, has rejoined the King Motor Car Co. of Detroit and will occupy the same position with the King Motor Car Co. as he has heretofore, assistant sales manager.

McGiehan in New Orleans—T. H. McGiehan, the late vice-president and general manager of the Motz Tire & Rubber Co., Akron, Ohio, has opened a large retail and wholesale automobile accessory establishment at 1527 Canal Street, New Orleans, La. Mr. McGiehan represents several leading manufacturers in the Southern States.

Houston Makes Change—J. A. Houston, for the past seven years with the United States Rubber Co., has purchased from George Graham the business of the Broadway Fuel & Oil Co. in Spokane, Wash., dealers in accessories. Before coming to Spokane Mr. Houston was engaged in a similar line in Chicago. U. S., Goodyear and Firestone tires will be carried.

Rosen Heads Wilmington Packard—The Packard Motor Car Co. of Philadelphia, Pa., will open a branch at 222 West Tenth Street, Wilmington, Del. J. H. Rosen of the Philadelphia establishment has been appointed manager of the Wilmington territory. This branch will have under its control the entire State of Delaware, Chester County and part of Delaware County in Pennsylvania, and Salem and Cumberland counties in New Jersey.

—

Dealer

Louisville Agent to Build—H. D. Bowman, Louisville agent for Chalmers, Pierce-Arrow and Rauch & Lang, will build an addition to his garage at Fourth and Oak Streets.

N. Y. Cadillac to Build—Bids are being received for the construction of a four-story, 60 by 100-ft. garage for the Cadillac Motor Car Co., 1881 Broadway, New York, N. Y. The estimated cost is $80,000.

Marmon's K. C. Quarters to Add—The floor space of the Kansas City branch of the Nordyke & Marmon Co. will be three times greater, in new quarters now being arranged at 1608-1610 McGee Street. The company has taken a 5-year lease on this new two-story and basement structure.

Jacksonville Overland in New Hands—R. T. Cassell has given up the Overland agency in Jacksonville and it has been turned over to a new firm composed of C. N. Priest and J. F. Claus. The new firm will have its salesroom at the Ford garage, although the new business will be kept entirely distinct from the Ford agency.

Spokane Studebaker Branch Opened—A. H. Brown of Portland, Northwest manager of the Studebaker corporation, has opened up a retail branch for Studebaker cars in Spokane. The Studebaker maintained a branch in Spokane 3 years ago, when it was discontinued and the eastern Washington, Idaho and Montana territory formerly under the Spokane office was transferred to Portland.

Ford Body Co. Makes N. Y. Lease—The Ford Motor Body Co. has leased the store and basement at 10 West 60th Street, New York City.

Republic Tire in Baltimore—The Tire Sales Co., 204 St. Paul Street, Baltimore, has taken the agency for the Republic tires.

New Tire Branch in Dallas—A branch office of the Dallas Double Tread Tire Co. has been opened at 1605 Young Street, Dallas, Tex. A. M. Loomis is in charge.

Detroit Dealer Moves—The McKenney-Devlin Co., Detroit distributor for the King and Haynes, has moved into its new sales and service building at 698-700 Woodward Avenue.

Fuller Battery in New Britain.—The Fuller Storage Battery Co., 62 Ann Street, representative of the Willard battery, has established a sub agency in New Britain, Conn.

In New Louisville Garage—The Oak Street Garage is now occupying its new quarters at 309 East Oak Street, Louisville, Ky. It is a one-story brick building of fireproof construction.

New Baltimore Accessory Agent—The Motor Supply Co., Baltimore, Md., a newly formed concern, has opened at Charles Street and Lafayette Avenue, with a complete line of accessories.

Green Bay Garage to Add—The Green Bay Motor Car Co., Green Bay, Wis., is contemplating the erection of a 57 by 65 ft. addition at the rear of the present garage, to give more room for repair shop and storage.

Portland Fisk Builds—W. C. Arthur, Portland (Ore.) contractor, will erect a one-story, 50 by 65 ft. brick building for the Fisk Tire Co., which will be located at the southeast corner of Couch Street and Broadway, Portland.

Opens Manchester Tire Station—J. B. McCrillis & Son have opened a service station and salesrooms at 1137 Elm Street, Manchester, N. H., to handle the Marathon, United States and Congress tires and other accessories.

New Buffalo Salesrooms Opened—The Poppenberg and Mutual Motor Car companies have opened new showrooms at Main, Carlton and Washington Streets, Buffalo, N. Y. The companies handle five makes of cars, King, Saxon, Apperson, Enger and Pullman.

No Longer a Branch—The Oakland is no longer handled in Boston, Mass., as a factory branch. L. B. Sanders, who went there two years ago as manager, has taken the business over as an agency and he will occupy the same quarters on Massachusetts Avenue.

Hartford Buick Makes Change—The Buick representation which has heretofore been vested in the Hartford Buick Co., which was also associated with the Buick agency in Springfield, Mass., has passed to D. B. Roberts, until recently manager of the Hartford Buick Co.

Louisville Co. Opens Showroom—The Callahan Motors Co., a new concern, which recently acquired the agency for the Chandler Six in Louisville, will open its new show room at 811-813 South Third Street. W. P. Callahan, who formerly resided in Arizona, is head of the concern.

Swinehart Tire in Louisville—The Independent Tire Co., which has secured the agency for the Swinehart tire, has opened a salesroom at 548 South Third Street, Louisville, Ky. N. B. Segal, president of the company, was formerly connected with the United States Tire Co., New York City.

Richards Machine to Increase—The Richards Machine Co., Milwaukee, Wis., manufacturing drill presses and special machinery, has arranged for a large increase in its production, particularly of repair shop equipment for garages, by the purchase of the plant at 3417-3419 Vliet Street, which it has occupied for several years, and adjoining acreage. C. J. Richards is president.

New Company Formed—The Regal Motor Sales Co. is the name of the new corporation formed to succeed the C. R. Robinson Co. for handling the Regal cars in New England with headquarters in Boston, Mass. Joseph Porter, who was one of the factory officials, is at the head of the company succeeding Mr. Robinson, and C. H. Klegge is still with the company as its treasurer.

Connecticut Ford to Remodel.—L. H. Elmer of the Elmer Automobile Co., distributor of the Ford in Hartford, Tolland, Windham, Middlesex and Litchfield counties, Connecticut, plans remodeling of the Palace Automobile Station at 348 Trumbull Street, which he recently acquired. The Ford interests will be grouped at the above location immediately alterations are made.

New Baltimore Concerns—After being used as a riding academy for 65 years, a property on Bolton Street, Baltimore, Md., is to be used as an automobile establishment. The property has been purchased by the Howell Motor Truck Co., H. D. Howell, proprietor. It contains about 8,000 feet of space. The Economy Tire Repair Works has been organized and has opened at 16 East Oliver street. W. E. Underwood is proprietor. Accessories also are being dealt in.

Recent N. Y. City Removals—The Hudson Motor Car Co. of New York, Inc., has taken possession of its new salesroom in the Circle Bldg., 1842 Broadway, New York City. The Hartford Suspension Co., Jersey City, has moved into a new salesroom at 1846 Broadway, New York City. The Franklin Automobile Co. of New York, of which G. H. Tisdale is the head, is now occupying its new salesrooms at 1848 Broadway. The Lozier Motor Co. has established New York City headquarters and salesroom at 1850 Broadway.

Goodyear Places New Ohio Agencies—The Goodyear Tire Co. has placed the following tire agencies in Ohio: Mansfield, I. F. Newcomer, Richland Motor Co., H. W. Smith, Mansfield Vulcanizing Works; Plymouth, Plymouth Garage; Shelby, M. D. Doty; Atwater, DeGraff & Biles; Beloit, W. H. Sanders; Berlin Center, L. E. Hawkins; East Rochester, Alfred Malin, F. H. Scattergood; Hanoverton, Conser & Wilson; Homeworth, M. Pilmer; Kensington, Oren Harsh; Marlboro, H. C. Slabaugh & Son; Minerva, Minerva Motor Car Co.; Sebring, Hall Machine Co.; Alliance, Alliance Auto Repair Co., Alliance Motor Car Co. and the Stark Cycle Co.

Hokanson Sells Buick Retail Business—The Hokanson Automobile Co., Buick distributor in Madison, Wis., has disposed of its entire retail business in Madison, Blooming Grove, Burke, Middleton, Verona, the north half of Fitchburg, the south half of Westport and the west half of Sun Prairie to James Doyle, formerly general manager of the Wisconsin Culvert Co. The business will be continued from the Hokanson headquarters on East Doty Street. The Hokanson company recently organized the Wisconsin-Oakland Co., with headquarters in Milwaukee, with Wisconsin, Northern Michigan and a portion of Minnesota as its territory for Oakland cars.

Recent Savidge Appointments—The Savidge Steering Device Co., Indianapolis, has recently appointed the following jobbers and distributors: E. Schoonmaker Co., New York; Klecker Shock Absorber Co., Minneapolis; H. F. Brownell Co., Sioux Falls, S. D.; Roy E. Warner Co., Louisville, Ky.; Herring Motor Car Co., Des Moines; The Fisk Co. of Texas, Dallas; Albany Hardware Co., Albany, N. Y.; Knepper & Knight, Detroit; Erie Rubber Co., Erie, Pa.; U. S. Rubber Co., Rochester, N. Y.; M. E. Remelin, Cincinnati; Fields & Rusness, Fargo, N. D.; City Auto Tire & Rubber Co., Cleveland; Iroquois Rubber Co., Buffalo; G. W. Shroyer Co., Dayton; A. W. Whitaker & Co., Memphis, Tenn.; Cox & Cummins, St. Louis; Burwell Smith Supply Co., Oklahoma City; Adams Alexander Auto Co., Sioux City; Wentworth Brown Co., Amesbury, Mass.; C. V. Reich, Pittsburgh; E. De Tamble, Los Angeles; A. C. Galbraith, Milton, Pa.; O. L. Hutchins, Chanute, Kan.; R. C. Weissmantel, Southampton, L. I.; Shoemaker Bale Co., Little Rock, Ark.; The Motor Shop, Indianapolis; Brant Bros., Indianapolis.

Schramm Building New Garage.—The Schramm Auto Repair Co. is building a new garage at 5610-5612 Easton Avenue, St. Louis, Mo.

Repairs Radiators in Columbus.—The Auto Radiator Repair Co. is the name of a new concern at 153 North Fourth Street, Columbus.

Motz Tire in Toledo—The H. P. Dodge Engineering Co. has been named Toledo distributor for the Motz Tire & Rubber Co., Akron, Ohio.

New Columbus Garage. — Harry Moore, formerly with the Columbus Buggy Co., will open a garage and repair shop at Broad Street and Wilson Avenue, Columbus.

Rothweiler Heads Seattle Truck—The Seattle Truck Co. is the latest to enter Seattle, Wash., headed by H. N. Rothweiler, with a service department at Broadway and Denny Way.

Duluth Co. Builds—The Western Automobile Co., Duluth, Minn., proposes to erect a two-story, 100 by 140-foot, fireproof building for salesrooms and repair department. The estimated cost is $50,000.

New Cleveland Welding Building—The Cleveland Welding & Mfg. Co., Cleveland, O., will erect a $26,000 factory addition to its present buildings on West 117th street. It will be of reinforced concrete.

Cleveland Ball Bearing Adds—The Cleveland Ball Bearing Co., Cleveland, O., is purchasing considerable new equipment, which, when installed, will give the company's plant three times its present capacity.

McNaull Tire Opens Branch—The McNaull Auto Tire Co., Toledo, O., has opened a branch in St. Louis, Mo., at 5032 Delmar Boulevard. The office has been organized as the McNaull Tire Co. of St. Louis.

Polson's New Plant—The Polson Mfg. Co., 27 Chenango street, Buffalo, N. Y., manufacturer of automobile parts, will build a two-story, 85 by 100-ft., reinforced concrete factory at Main street and Lafayette avenue.

To Handle Accessories—The Pettibone-Peabody Co., department-store operators at Appleton, Wis., proposes opening a department for the handling of automobile accessories and supplies.

Perfection Starter in Hartford.—D. S. Rich at 64 Allyn Street, Hartford, Conn., has taken on the agency for the Perfection motor starter in the State of Connecticut, and the Stone shock absorbers in Hartford County.

To Repair Jitneys—The Worcester Motor Carriers Corp. has been formed at Worcester, Mass., to make a specialty of keeping in shape all machines that are used in the city for jitney lines. The company plans to operate a jitney line of its own after looking over the territory.

Garford Service in Frisco—A. W. McKenzie, district sales manager of the Garford Motor Truck Co., is at present in San Francisco, planning to establish a direct factory branch for the recently reorganized Garford company.

Springer Manager.—The Standard Auto Co. has opened a one-story garage, 60 by 70 ft., at 648-650 West Bridge Street, Grand Rapids, Mich. R. F. Springer is manager. A general repair and supply business will be conducted.

Packard's Chicago Service Station—The Packard Motor Car Co., 2357 Michigan avenue, Chicago, Ill., has purchased the site at 2340 Indiana avenue, and will build a five-story, reinforced-concrete service station, to cost about $125,000.

S. K. F. Increases Office Space—The S. K. F. Ball Bearing Co. has increased its office space in the Hudson Terminal Bldg., New York City. Within the last 4 months it has about doubled its offices, so that now they occupy a full wing on the sixth floor.

New Garage for Pomona — The new brick garage now in process of construction for the firm of Potter & McCormick on South Thomas street, gives Pomona, Cal., a string of four garages which have sprung up within the past few months ranging from $3,000 to $7,000.

Gets Goodyear Truck Tire Agency—J. E. Power, supervisor of San Francisco, Cal., has secured the agency for the Goodyear truck tire and has opened a service department on Van Ness avenue in that city. The name of the new concern is the Motor Truck Tire Service Co.

Toledo Garage to Move.—The United Garage Co., Toledo, Ohio, has arranged to move from its present location to larger quarters at Ontario and Jefferson Streets, about September 1. The company has taken a 20-year lease on the premises. M. R. Himes is general manager.

New Vancouver Garage.—W. F. Silver has opened a garage at Central Park, corner of Kingsley and Silver Avenue, Vancouver, British Columbia. In connection with the garage he will maintain an up-to-date service station, stocking Pennsylvania Vacuum Cup and Congress tires as well as accessories.

Hupmobile Opens Newark Salesroom.—A new salesroom for the sale of Hupmobiles was recently opened at 200 Halsey Street, corner of Branford Place, Newark, N. J., by the newly-formed firm of De Cozen & Riess. The firm consists of Alfred De Cozen and George L. Riess, vice-president of Chas. E. Riess & Co., Inc., Metropolitan distributor of the Hupmobile.

Milwaukee Co. Dissolved—The Graper & Paulus Welding Co., 254 Fifth street, Milwaukee, Wis., has retired from business and the partnership between F. E. Graper and Wenzel Paulus has been dissolved. The concern was a pioneer in Milwaukee in the welding, cutting, lamp and radiator and fender repair business. Practically all of its trade was in the motor car business.

To Make Motor Brushes—R. H. Seabury, a chemical engineer of Wellesville, N. Y., has located in Toledo, O., to manufacture motor brushes, used on electric motors. Mr. Seabury is the owner of the patents. Large orders for the brushes have been placed by the Electric Auto-Lite Co. Seabury has received his machinery and the factory will be in operation in the near future.

Cartercar Service Station Opened.—A new Cartercar service garage is now in operation at 1822 Hendrie, near Woodward Avenue, Detroit, Mich. It is managed by W. D. Block, who was comptroller of the Cartercar Co., Pontiac, Mich. This service station has been established because the Cartercar Co. discontinued its local branch and service department some time ago.

Leavitt Co. Agency in Fresno—J. W. Leavitt & Co., Pacific Coast distributor of the Willys-Overland Co., has established a branch in Fresno. Calvin C. Eib, executive supervisor of the company, is at present in charge of the new branch and is installing a service system and perfecting the general workings. The company will occupy a space 50 by 150 feet in the main section of the town.

Hegeman Heads Milwaukee Firestone.—The Firestone Tire & Rubber Co., Akron, Ohio, has permanently established a Milwaukee factory branch in the new Oxford building at 481-483 Jefferson street, which provides nearly 12,000 square feet of floor space and stockroom for 7,500 casings. J. L. Hegeman is in charge as local manager. Practically every important tire manufacturer now has a direct factory branch in Milwaukee, and nearly all are located on Milwaukee, Oneida and Jefferson streets, built up during the last three years as Milwaukee's tire row.

Hartford Oakland Makes Alterations.—The A. C. Hine Co., Hartford, Conn., is making alterations in the store at 314 Pearl Street which, when completed, will be used as a salesroom for Oakland cars for which the concern recently signed up for the State of Connecticut. The basement will be used as a service station. A. C. Hine, formerly general manager of the Overland-Connecticut company, is the prime mover in the project and with him are associated his father, D. H. Hine, and E. N. Humphrey of the Traut & Hine Co. of New Britain. R. J. Flynn, formerly with the Auto Tire Co. as an Oakland salesman, has joined the Hine forces.

VOL. XXXIII NEW YORK—THURSDAY, JULY 22, 1915—CHICAGO No. 4

The AUTOMOBILE

$108,191,774 for Roads in 1914

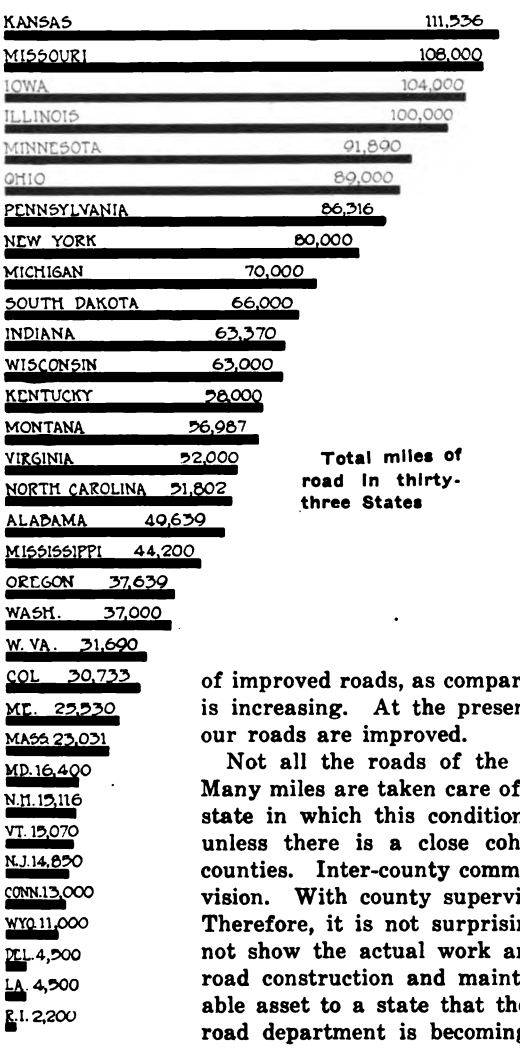
Over 6,000 Miles of New Road Added and Over 35,500 Improved During Year 1914 in 33 States

By J. Edward Schipper

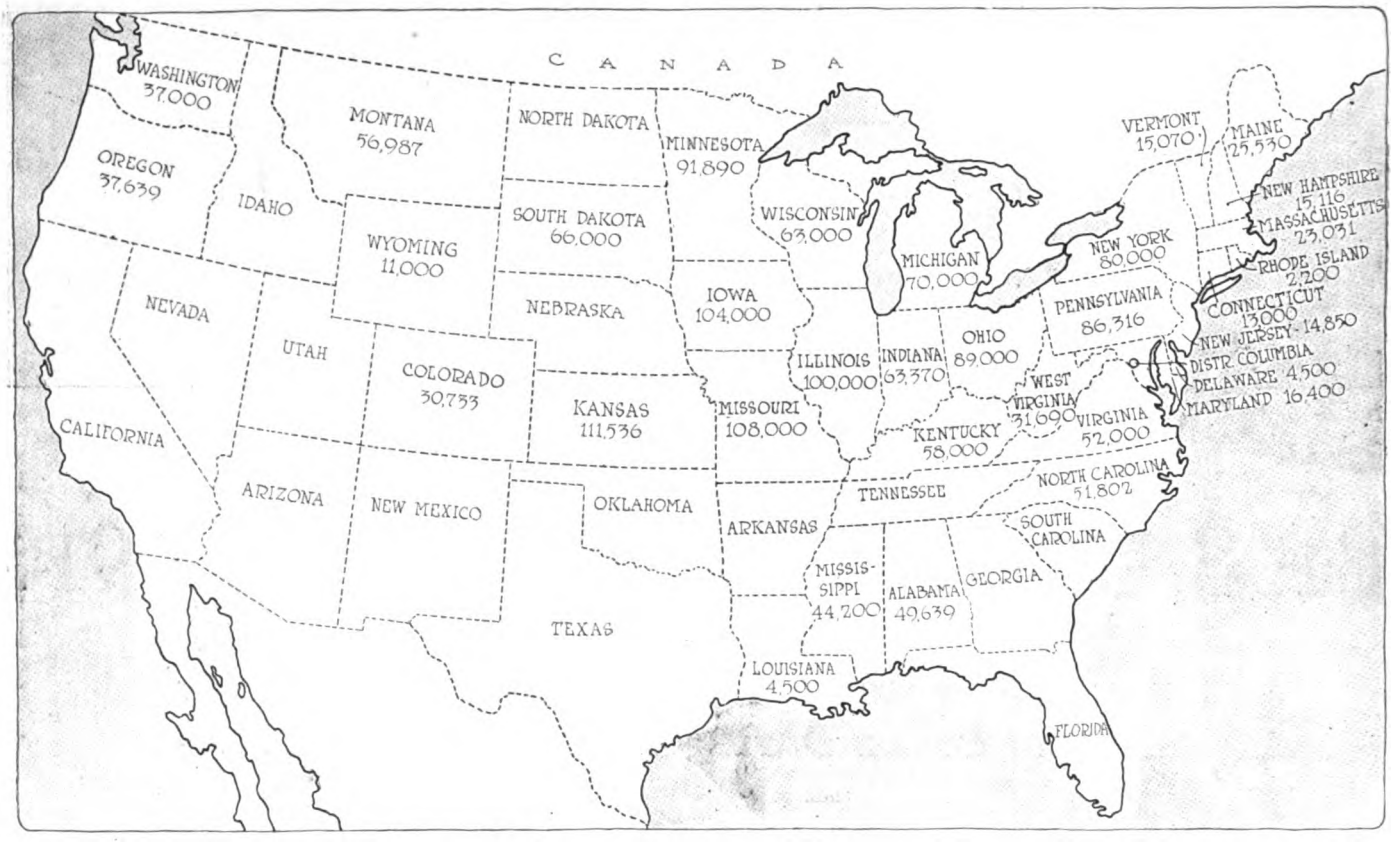
STRETCHED out in a single line the roads of the United States would encircle the globe more than eighty times. Traveling at the rate of 150 miles a day, it would take 36 years, or 13,000 days, to travel their length. The value of these roads is stupendous. At the lowest possible estimate of construction, $1,500 per mile, the value of the 2,000,000 miles of road in the United States is $3,000,000,000, but the sum which has been expended on the construction and maintenance of these roads is so far above this, that it would be impossible to even form the roughest estimate of the true amount of money spent for highways in this country.

Most of our roads have been gradually developed from the forest path to the highway. Even in our largest cities, the pathways that the oldest settlers followed in their trips to and from fresh water springs have been perpetuated in the form of streets. The old stage routes from city to city have become the automobile highways of the present day. Examples such as the old Albany trail, the Boston Post Road and the Boone Way are repeated all through the country. If present indications hold true, the pathways that the Forty-niners marked with the bleached bones of those who perished along the rigorous route will become part of an ocean-to-ocean boulevard.

While these gradual developments of some of our best known highways have been up to within recent years the greatest factor in the development of the highway system of the country, the automobile has introduced another factor which has become preeminently important in the road-building industry: The automobile stands for efficiency and anything with which it has to do follows its lead of well directed effort. The automobile road, unlike the old Indian trail, does not follow a serpentine course, but like the iron railroad path, follows the straight line, the shortest distance between the two objective points. The greatly increased speed of travel has brought the necessity for direct routes and smooth roads. In the days of the horse, the dirt road was good enough; in the day of the automobile—the present time—it no longer suffices. With the speed at the command of the motorist, irregularities in surface must be flattened out before the speed can be used. Rapidly the percentage of improved roads, as compared with the total roads in the country, is increasing. At the present time, approximately 7 per cent. of our roads are improved.



Not all the roads of the country are under state supervision. Many miles are taken care of by town and county authorities. A state in which this condition holds true is under a disadvantage unless there is a close cohesion of plan between the different counties. Inter-county communication is assured with state supervision. With county supervision it ought to be, but often is not. Therefore, it is not surprising that records from many states do not show the actual work and the actual results accomplished in road construction and maintenance. The roads are such a valuable asset to a state that the necessity for a well organized state road department is becoming recognized throughout the country.



Map showing number of miles of road in states scattered throughout the Union. The mileage includes all types of roads

More and more the state engineering department keeps its fingers upon the pulse of the road situation and by means of well organized effort and carefully kept statistics are systematically solving the road problem of the state.

Statistics from 33 States

Statistics gathered from the thirty-three states throughout the Union, in which records are carefully compiled, tell an interesting story of what this country is doing to keep its lines of communication from district to district in the best possible condition. In these thirty-three states there are 1,614,999 roads of all kinds. Of these 226,288 are improved, 35,704 miles having been improved during the year 1914. At the rate of 35,000 miles per year, these thirty-three states will have their entire mileage classed under the head of improved roads in less than 45 years. In these states during the year 1914 there were added 6,006 miles of new roads. Before the advent of the automobile, such a thing would have been unprecedented, but now it is becoming a yearly occurrence and gathering impetus as time goes on. In 1912, for example, these same states added over 5,000 miles of new roads and transferred from the classification of Roads of all Classes to Improved Roads more than 35,000 miles.

$108,191,774 in Twenty-nine States

All these improvements mean that money must be spent, and, again, drawing figures from the thirty-three states which are tabulated by name on page 141 the amount which it has been found necessary to expend will be perceived. During 1 year twenty-nine of these states expended $108,191,774. The greatest amount spent by any state was Indiana, which paid out $17,000,000. New York followed closely with $14,638,045; Iowa expended $11,000,000; Colorado spent $9,964,077; Wisconsin paid out $7,000,000; Montana, $8,389,278, and Illinois, $5,500,000. Thus, throughout the entire country it can readily be seen that the realization of the value of good roads is becoming complete. The citizens of these states are backing their knowledge of the necessity of these roads with millions of dollars. They have made the subject of roads of paramount importance in local politics and more careful supervision is being exercised.

Dirt Roads Predominate

America's representative road is still the dirt road—even a large percentage of the improved roads are dirt. Throughout the Union there are probably more than 1,250,000 miles of dirt road. In the thirty-three states from which records are available, there are 1,005,436, and even this is not an exact figure because many miles of highway in one state would be called a road and in another it would not. Even in the State of New York, with its millions of people, there are wild regions throughout the mountainous northern sections where mere trails are known as roads. The natives of this part of the state refer to old abandoned lumber trails as roads; whereas, as a matter of fact, they are impassable for any vehicle heavier than a buckboard. With the understanding that a dirt road, however, is any road composed of natural earth and which is passable in fair weather, the figure is quite accurate.

Among the improved roads the gravel construction is most typical of America, because the materials for its construction are generally quite close to hand and it is, therefore, possible to make good roads at a low cost. Taking the figure totaled from the estimates of the thirty-three representative record-keeping states, there are 78,846 miles of this type of road, or roughly, one-twelfth as many miles as of dirt. Ohio is the leader in gravel road mileage, having more than 14,500 miles of this type of road. Minnesota is next with over 11,400; Wisconsin has 7,000, and even little Rhode Island, with its total of 2,200 miles of roads, has 100 of these in gravel. Some of the states among those which keep careful state records of their highways have no gravel whatever. These are Connecticut, Delaware, Pennsylvania, South Dakota, West Virginia and Wyoming. Some of these states have roads of a composite type which resemble gravel to a great degree, but which are not the true gravel roads.

Macadam is probably the king of the automobile highways. When the average automobilist finds himself upon a newly finished macadam road he generally leans back against his seat and settles down for a period of comfortable riding. Ohio is the leader in macadam mileages, having 3,000 miles more than the second macadam state, Illinois. The respective mileages of macadam roads in these two states is 7,000 and 10,000. Kentucky has 6,000. Massachusetts, with its fine highway system, has 3,783. New York has 3,200, Wisconsin has 2,000, New Jersey 2,600 and North Carolina 1,209. Many states, such as Louisiana, have no macadam roads at all in the state. The total in the thirty-three states considered is 42,499. The other roads which are used to a sufficient degree to be separately classified are not many. Concrete and brick compose the majority of the other improved roads, but these have not reached a sufficiently high figure to be a vital factor when considered against the total. Many states are trying concrete on an experimental basis at the present time and it may be that this material, which has left such a heavy mark upon the building industry, will also be a factor in road development.

15,000 Miles New Road for 1915

To get the greatest mileage of roads at the least possible expense is one of the biggest problems that the state administration has to face. If a man wishes to construct a driveway from his front gate to his garage he is often appalled by the estimates of the contractors who aim to do the work. Yet, he has only 200 or 300 feet of road to construct perhaps and this is not apt to be of a nature to endure any appreciable traffic. When 1,000 miles of road is considered, the amount of money which its construction entails is so great that even a slight percentage of saving in any direction amounts to far more than the salary of the most highly paid engineers. Throughout the country in 1915 there will be perhaps 15,000 miles of road constructed and 35,000 miles improved. Already there have been $40,255,344.31 appropriated in fifteen states. There is no wonder that the road question is one of the biggest factors in internal politics in this country!

Convicts Used in Road Building

One of the big factors in recent years has been the employment of prison labor on the road. In the second annual report of the state highway commission of South Dakota, in making their recommendations to the Governor, the statement is made that the movement to have the prisoners of the state work on the highways has been enacted into a law in the states of California, Colorado, Oregon, Washington, Ohio, Virginia, West Virginia and others with splendid results to all concerned. The state is benefited by the material gain of good highways and by the moral and physical improvements of its charges. The prisoner is benefited from the physical and reformatory standpoint. This experiment has positively proven that the prisoners have profited by the fresh air and sunshine, were willing to work hard and looked forward to the next spring when they might again be so employed.

The Honor Camp

The State of Washington which successfully employs convict labor maintains what are known as Honor Camps. In this state under the indeterminate sentence law, convicts are given a minimum and maximum term and the plan is to place such convicts in the service wherever possible. The scheme is to allow the men a credit of 1 year's time for each 9 months' service on the road, arranging the term of service of the men, that when their 9 months' labor expire they will be discharged. The men are well fed, comfortably clothed and provided with well-equipped sanitary quarters. In general, the men prefer to serve in the quarry rather than in the penitentiary, and the results of their labor show a marked increase in efficiency. It has been found that the average cost of subsistence per man per day is 26.8 cents and the average cost of maintaining each convict per day including guarding, subsistence, clothing, items of general expense, medical,

Table of Highway Statistics of all States in Which Figures are Available

STATE	Total Miles of Roads in State	Total Miles of Improved Road	Miles of New Roads Built in 1914	Miles Improved Road in 1914	Miles of Macadam Roads in State	Miles of Brick Roads in State	Miles of Dirt Roads in State	Miles of Gravel Roads in State	Miles of Other Roads in State	Total Amount Expended for Roads in 1914	Amount Appropriated by State for Road Work in 1915	Remarks

escapes and transportation is 74.5 cents per day, giving a total cost of maintenance per convict per day of $1.83.

Washington's Pledge System

Working of convicts on highway under which has been called the honor system is an experiment in which the State of Washington has probably operated the most extensively of any state in the Union. Each convict signs the pledge of honor that for the clemency extended by the Governor and the state Prison Board for permitting him to work in the honor camp and the payment of 50 cents for each day's labor he agrees to perform such work as may be assigned to him and not to leave the camp without permission. Upon the acceptance of the conditions of the pledge, the Governor issues a conditional pardon to each man. The disposition of the honor men toward the system is in general very favorable. The freedom of the camp and the life in the open appeals to the men with the results that the work is done well and very few fail to keep their trust.

Bridges Bring Up Cost

Bridges are one of the big factors in raising the cost of road construction and in some states are a serious factor owing to the large number of small streams which must be crossed. In the State of Minnesota, for example, there are 20,603 bridges over 10 feet in length. The roads in this state are largely under the jurisdiction of counties, but in 1914 a new law went into practical effect which gave direct state supervision. However, the cost of the roads is to a large extent borne by the counties under the state aid system in which the state furnishes a part of the money required for road building. The county of Murray, which is 704 square miles in area, has 568 of these bridges, or in this county, in other words, for every twenty inhabitants there is a bridge. In the county there are 1,200 miles of road, or 9.8 people for each mile of road. To look at it from another angle there is a bridge for every 2.1 miles of highway. It is evident that road construction in counties such as these will be an expensive undertaking, and this is only a random example which is probably exceeded in many parts of the Union.

Kansas Leads in Mileage

The greatest road state in the country is Kansas with 111,536 miles. It has increased from 98,000 in 1912 when it was in fourth place. Missouri, which in 1912 had the highest mileage in roads, has now dropped in second place with 108,000, the same number it had at the end of that year.

Movement Is Nation-Wide

Iowa is now third with 104,000 miles of road; in 1912 it was second with 102,000 miles. Illinois has dropped from third to fourth place since 1912, having 100,000 miles of road. Thus there are continual changes in the mileages of the states, but one prevailing factor dominates the entire road building situation. This is the relative percentage of improved roads to total roads. Slowly this figure is advancing up the scale as the enlightened legislative bodies perceive the necessity for good roads. In 1912 the percentage of improved roads, as compared with total miles of roads, was a little over 6 per cent. In 1915 it is about 8 per cent. The advance is nation-wide. It is being demanded by farmers, manufacturers and merchants. It is not confined to one class, nor to cities or the country but is one universal movement which is reflected throughout all the industries of the United States.

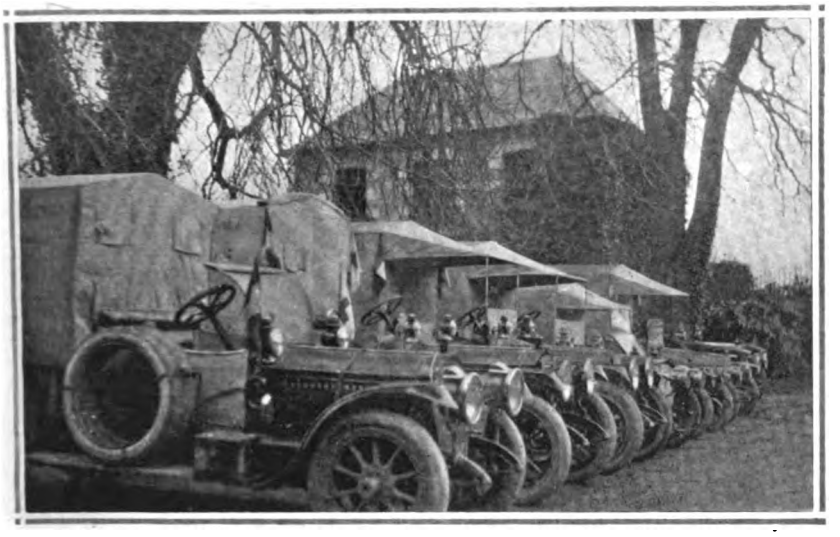
Road Models for the Public

The Office of Public Roads of the United States Department of Agriculture made an exhibit of road models for the first time in 1909 at the Alaska-Yukon-Pacific Exposition. The aim was to put on view such striking examples in miniature of model roads that visitors would not only appreciate the beneficent effects of improved roads but would, at the same time, be able to understand the methods of their construction.

Since the Alaska-Yukon-Pacific Exposition closed, the exhibit of the Office of Public Roads has been displayed at Omaha, Neb., during the National Corn Exposition; at Knoxville, Tenn., during the Southern Appalachian Exposition; at Chicago, Ill., during the National Land and Irrigation Exposition; at New York City during the Travel and Vacation Exposition and the Domestic Science Exposition; at Atlantic City, N. J., during the American Road Congress; at Lethbridge, Alberta, during the International Dry-Land Congress; at Buenos Aires, Argentina, during the International Agricultural Exposition; at Turin, Italy, during the International Exposition; and at various other expositions and fairs. The models have also been displayed on road trains at all important places along the route of the Pennsylvania Railroad in the State of Pennsylvania and along the entire system of the Southern Railroad, also along the St. Louis & San Francisco Railroad, the Atlantic Coast Line, the Nashville, Chattanooga & St. Louis Railroad, and the New York Central & Hudson River Railroad. A comprehensive exhibit of these models, illustrating all standard types of construction, has been installed at the Panama-Pacific Exposition.

American Cars in Red Cross Work

Day and Night Trips to Firing Line for Wounded



Fleet of automobile ambulances attached to field hospital at Montdidier

HOW Packard automobiles and American volunteers assisted in Red Cross work on the Allies' front is a thrilling story told by Curtis Goode, brother of the Paris manager of the Packard company. When the French armies took up their present position, after the Battle of the Marne, H. H. Harjes, of the banking firm of Morgan, Harjes & Co., secured from ex-minister of finance Klotz the use of a suitable building at Montdidier, and furnished it at his own expense as a field hospital. The Packard company supplied eight touring cars which were quickly transformed into ambulances and placed in the hands of volunteer drivers operating under the control of the French army. Curtis Goode was one of these drivers.

5-Mile Trip with Wounded

Although the Packards were directly attached to the Harjes hospital at Montdidier, they were at the call of the chief military doctor of the district, and had to take cases either to their own or other hospitals, as directed. From October to May the automobiles have been engaged in the task of making trips from the hospital to the firing line, the nearest point of which is only 5 miles away, and of bringing in the wounded. For 8 months the sound of guns has been so continuous that when a member of the hospital staff comes home on leave he finds the quiet of the city oppressive. Day and night, at irregular intervals, the call would come for ambulances to bring in wounded. Where road conditions allowed it, the ambulances went close behind the line of trenches, picked up the wounded men who had been carried out by their comrades, and hurried off with them to the hospital. By this rapid treatment thousands of lives have been saved and the men have been spared suffering inevitable with slower methods of transportation.

This portion of the front has undergone no change since the month of November. Both French and Germans are strongly entrenched, with a distance of only 100 yards between them. The position evidently is not of sufficient strategic importance to warrant the loss which would be sustained in a determined attack. Thus the men sit watching one another, and occasionally have the monotony relieved by heavy bombardments. Fortunately for the men, this kind of warfare is not very destructive. Curtis Goode relates that one evening the Germans began a bombardment on a serious scale. During the entire night big guns boomed as rapidly as if the huge shells were being fired from a machine gun. Occasionally a French gun joined in the welter of sound. Every window in the hospital trembled and rattled from 6 p. m. to 8 o'clock the next morning. The automobile staff was up early, expecting to have a busy day. The net result of the night's heavy firing was eight wounded cases.

A Trip to the Trenches

One of the experiences of which Curtis Goode has the most lasting remembrance is a trip he was allowed to make one night into the front line trench held by the French. "We set out from the hospital in a car," he stated, "and for the last 2 miles had to drive in complete darkness, for even a side light would have been observed by the enemy. At an indicated point we left the car in a farm building and proceeded ahead on foot. At this point there is a main communication trench 2 1-2 miles long leading right up to the French front line trench, but having branches off it to other trenches. During the daytime this main communication trench has to be used throughout its entire length.

"In this district numerous shells have exploded on the roads, but they have not made traveling impossible. On the main highways the surface is so hard that the shells do not penetrate and the damage done is annoying only at night if running without lights. On the lower class roads, with little more than a dirt surface, greater damage is inflicted and it is sometimes impossible to pass until soldiers have filled in the holes."

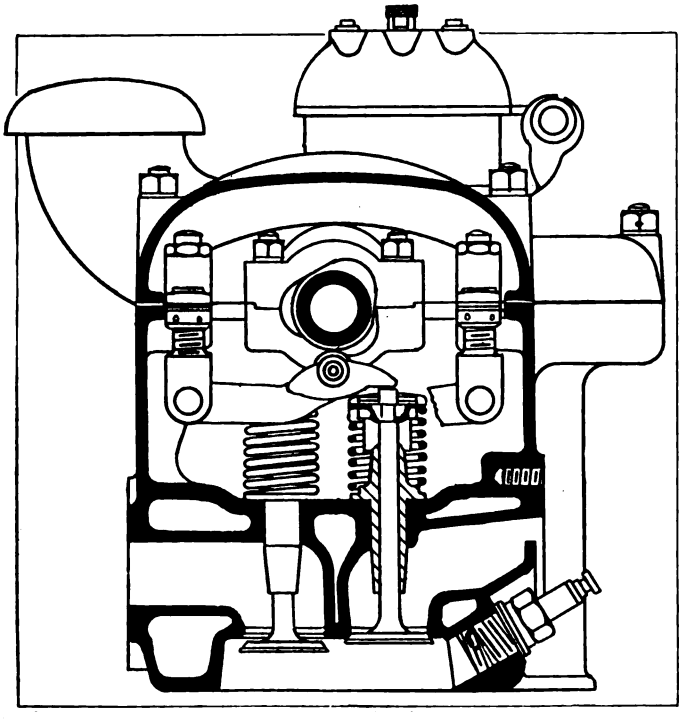
Chalmers Valve-in-Head Motor

To Be Principal 1916 Product—Good Acceleration and High Gear Ability—Rear Axle Gearset



Section through Chalmers valve gear showing rocker arms and tappet adjustment

FEW of the new cars appearing at the New York show last January attracted more attention by virtue of their design than did the new Chalmers with valve-in-head motor, on account of the remarkably clean outline of the engine and the chassis as well. Naturally with so much novelty of construction as was present in the motor, the performance of the cars on the road has been watched with interest, but the fact that the manufacturer is continuing the same chassis practically unchanged is the best proof that the new motor has worked out very well.

The Chalmers Motor Co. has three cars for 1916, and of these the 6-40 is the principal product. The 6-48 and the Master six are continued, but it is not anticipated that there will be so large a demand for these as for the smaller car.

Of the 6-40 there are two types, five-passenger and seven-passenger, the latter having 4 in. more wheelbase and semi-elliptic rear springs instead of cantilevers as used on the five-passenger. These two models are priced $1,275 and $1,350 respectively. The 6-48 which has a T-head motor and some other small differences in design costs $1,550 with a seven-passenger body, and the Master six, $2,175 with touring body.

For fitting to the 6-40 a new body is being developed which is either a standard open touring affair or a sedan, and the attachment of the upper works is made in a highly ingenious and secure manner. Whether the car is open or closed there is nothing to show that it is convertible and in the closed condition the appearance is handsome. This new body is not yet in production, but will be available later on.

Camshaft Driven Centrally

Coming back to the 6-40 chassis the unique feature of the motor is that the overhead camshaft is driven at its center by a large worm gear and to obtain a similar drive at the center of the crankshaft the middle bearing is divided into halves. This makes a four-bearing shaft and it is remarkable that it has been possible to get the middle bearings of such good width. Having a bore of 3.125 in. and stroke 5 in. the motor is intended for high speeds. Crankshaft rigidity has been obtained by using a 2.25-in. shaft and rigidity of crankcase by very rigid web work around the center bearing supports, and the use of a box form of crankcase with sides that come much lower than usual. This type of case is not uncommon where the bearings are put in endwise being first mounted on the shaft, but it requires considerable ingenuity to arrange them as in the Chalmers so that they can be scraped in with the shaft in its proper place. The detail of the design can be observed in the section of the motor on the opposite page.

The cylinder block consists of three portions, the lower in which the pistons work is as simple a casting as could well be made. On this rests the head casting which carries the camshaft, the valves and the spark plugs, while on top of all is an aluminum cover.

Compound Lubrication

Two features of great convenience to the driver are the positions of the ignition distributer and the oil filler, since both these parts are above the top cover, as can be seen in the photographic reproductions. Oil is poured into the camshaft case where some small part of it remains, and the overflow passes down the space surrounding the camshaft drive shaft to the base.

With an overhead-valve motor and an overhead camshaft also lubrication is liable to be troublesome, because enough oil must be pumped to the top and yet the supply to the camshaft kept down sufficiently to prevent flooding the valves. In the Chalmers the camshaft is hollow and a small hole is drilled through each cam, at the center there is a supply for the skew gear and, of course, holes for the supply to each bearing. Oil is pumped to the front end bearing direct, and thence passes along the shaft, but the size of the outlets prevents too much lubricant reaching the valve compartment.

Sundry gutters serve to catch what little drip there is and to conduct the oil back to the shaft tunnel whence it returns to the crankcase. For the crankshaft there is a supply to each main bearing, all the oil leads being copper pipes, and dip troughs are used for lubricating the connecting-rod bearings. Splash cares for the pistons in the usual way.

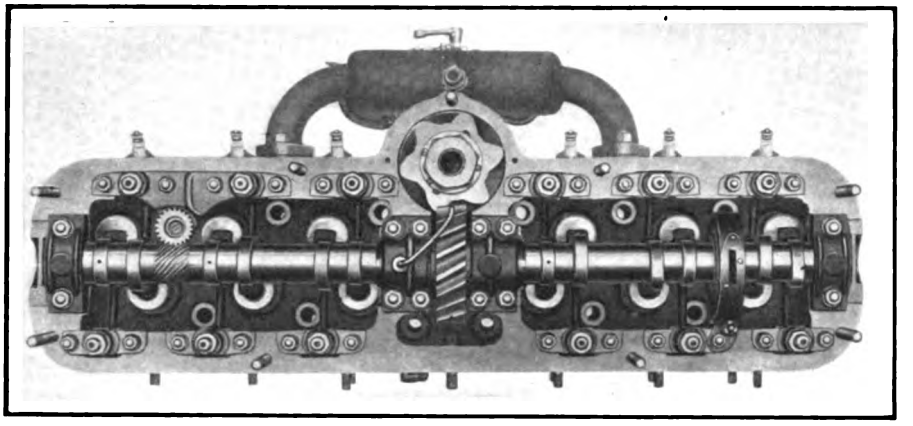
The same vertical shaft which drives the cams is used for the oil pump drive, as the pump is mounted directly beneath it and connected by a short, jointed shaft that allows the pump to be taken off for cleaning without disturbing other parts.

Accessories Disposed Neatly

Having all the valve gear on top of the motor means that the generator and starting motor can be put in any convenient place alongside, without interference with other parts. Thus, instead of the starting motor being low down and almost in the mud pan as it sometimes has to be, it is carried high on a bracket on the crankcase side. There are several bearings and joints in the mechanism which slide the pinion into mesh with the flywheel rim gear, and the high

The New Chalmers Valve-in-Head Motor

Chalmers 6-40 valve-in-head motor which is 3.125 by 5 in. Observe the large camshaft driving gears and the arrangement of the oil pump at the foot of the vertical shaft. The easy intake and outflow for the gas can be appreciated from this view. Note also the construction of the crankcase which is designed to give extreme rigidity



View of Chalmers valve mechanism as it appears when the aluminum top cover is removed

placing of the motor makes these points very easy of access.

A very simple and yet completely effective means for adjusting the generator drive chain is employed, this being made possible by the method of support for the motor. In the crankcase are two large holes, one at each end, extending transversely clear through the aluminum, and steel tubes are put through these holes to form the crankcase arms.

The Gray & Davis generator is hung just beneath the right hand end of the front tube, where it is sufficiently accessible for all purposes, and the bracket which holds it is gripped to the crankcase supporting tube by a clamp screw. The drive chain is outside the crankcase, as can be seen in the photograph, so, by slacking the clamp screw and gently tapping the bracket along the tube the chain can be brought to any desired tension and held there by a turn of the clamp. The whole operation of adjustment can be performed very easily and quickly.

Careful Balance a Feature

It is well known that the main trouble in the way of producing a successful high speed six is the vibrations which arise in the crankshaft. To eliminate these is partly a matter of design and partly one of manufacture. From the drawings can be seen the way in which design affects the Chalmers motor, for not only is 2.25 in. very large for a 3.125 bore motor, but the crank webs are also very substantial. The box form crankcase must help a good deal and no doubt the divided middle bearing is, from the rigidity viewpoint, the equivalent of a bearing the full 4 in. long.

In the factory processes there are two balancing operations, one for the flywheel and the other for the crankshaft, the parts being run on a special machine designed by the Chalmers engineers and developed from a couple of known tools into a much simpler form. The operation consists of running the parts in one direction only and balancing by drilling the flywheel rim or the crankpin.

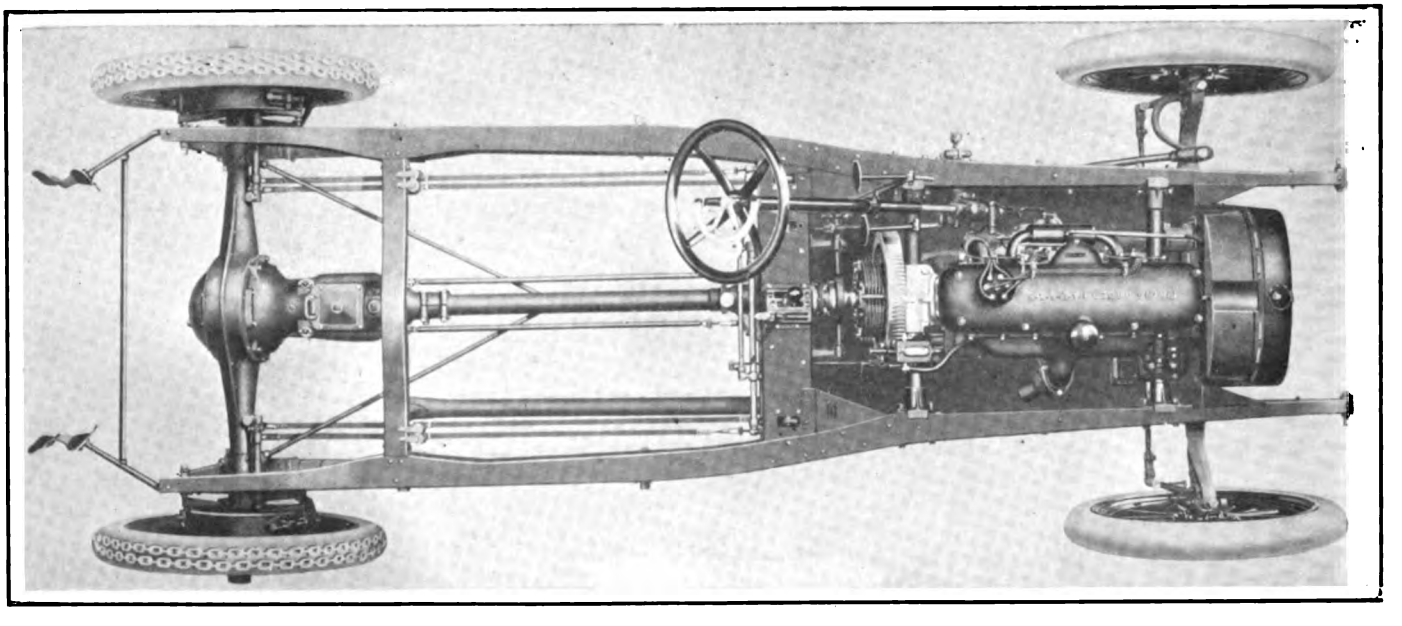
This method of handling the crank is made possible by the absence of internal oilways in the shaft, as frequently a quite large amount of metal has to be drilled out. Skill and experience of the workman count for almost everything in this operation as a practiced man can judge in a moment where it is that the shaft is heavy and to get smooth running at 1500 to 2000 r.p.m. very little inaccuracy is permissible. The crank webs are not machined externally, of course, as this would be of but little use. It is said that shafts and flywheels balanced on the special machines which Chalmers uses are always in static balance when their running balance has been corrected, which is not always the case with some other methods.

Tubular Connecting-Rods

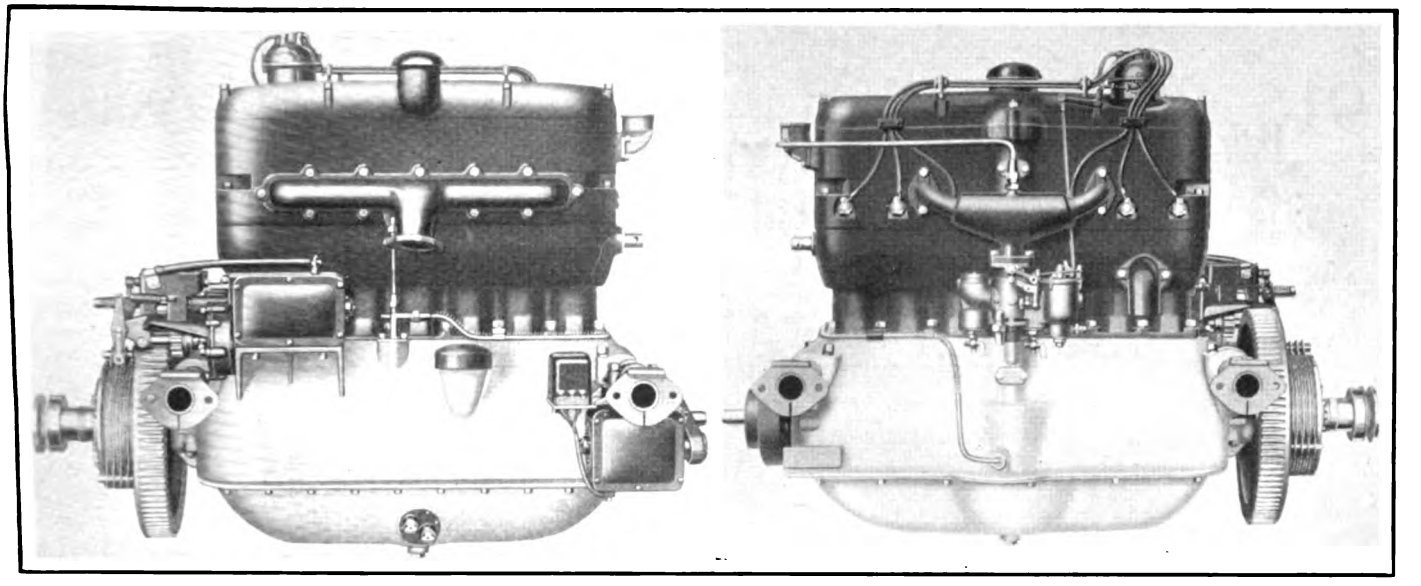
Another small detail that is of interest is that the round-section, hollow connecting-rods have small holes drilled through them near the bottom, this being to allow the escape of any oil which might find its way inside. As the rod is drilled right through the hole at the upper end is closed only by the piston pin bushing, and it is possible for oil to slowly work its way past this bush and so gradually fill up the rod. If this happened to one rod and not to the others the balance of the motor would be interfered with seriously.

Lightweight Axle Gearset

Back of the motor is a simple form of dry-plate clutch with a light action and a very decided grip, and then comes the short double universal to which the front end of the drive shaft attaches. Chalmers pins its faith to the rear axle gearset so that the chassis divides into but three main assemblies, the motor, the gearbox and the frame with springs and front axle. To cut the unsprung weight a carefully designed aluminum gearbox is used and another point which should



In this plan of the Chalmers 6-40 chassis notice that the springs are all under the frame and observe the direct brake connections. These latter are strips of thin spring steel which cannot rattle



Left—Exhaust side of Chalmers motor, showing Gray & Davis generator and starting motor. The cap on the crankcase side is a breather only as the oil is all put in through the top cap. Notice the accessibility of the Atwater Kent distributer. Right—Intake side of Chalmers motor. Observe the fins on the oil supply pipe which cool the lubricant on its way to the bearings

be mentioned is that the gearshifting rods are laid out on such centers that rough roads and high speed combined, have no tendency to throw the gearshift lever to and fro. This is a fault to which some rear-axle-gearset cars have been somewhat prone and to eliminate it is not quite so simple as might appear.

It is not easy to describe a car like the Chalmers, which is designed and made in its own factory and does not depend on assembly parts, without running to great length, so, having considered the main units of the chassis, the others may be hastened over a little. First, the brakes are 14 by 2 in. and 14.375 by 2.25; all rods and links are arranged to have a straight pull and the levers are well proportioned, so that plenty of arresting power is available without heavy pedal pressure. Again, special pains are taken to make the steering free and precise, this being a matter of large thrust bearings and a proper setting of the front axle swivel pins.

In the side view of the chassis the substantial support toward the middle of the cantilever spring can be seen, also the long shackle which permits very free action at the front. Putting the middle spring support *under* the frame instead of alongside it removes all twisting stresses on the side rail and saves weight in the brackets and attachments. In practice the springs behave in a most exemplary manner giving easy riding over the worst possible dirt roads and yet the rear springs are free from roll.

Car Performance

In a short demonstration run over a particularly vile piece of sand road near the Chalmers factory it could be noticed that there was very little tendency for the car to plunge, even with the rear seats unoccupied, and incidentally the same run showed the ability of the motor to pull smoothly on high gear through fairly heavy going. Naturally, one would expect plenty of high-gear ability with a 5.25 to 1 ratio, but a good deal of vibration round about 30 m.p.h. would also be anticipated and this most certainly does not occur even at speeds a good deal above this. The Rayfield carbureter suits the motor well and provides a very good acceleration, a couple of trials on a brick road showing from 5 to 30 m.p.h. on high gear in between 14 and 15 sec.

The touring bodies have an almost straight-line side and the high hood makes the car look powerful. Ample leg room and upholstery deep enough to give the soft feeling of a good arm chair, combined with careful finish, are the principal characteristics. Equipment is complete and includes a particularly handy rain vision windshield. Tires are 34 by 4 in. all around and there is one spare demountable rim. There is no need to mention everything in the smaller detail save to remark that it is in proper keeping with the character of the chassis.

—

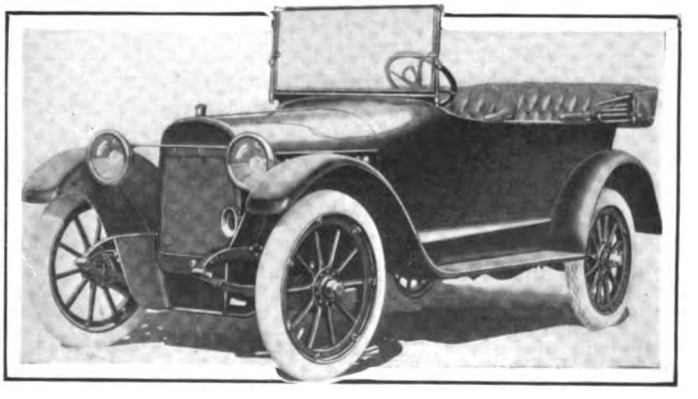
New Washington Law Is Sensible

TACOMA, WASH., July 17—It is the opinion of the automobile dealers of the State of Washington that the new motor vehicle code is being administered in a common sense manner by State officials and particularly by the Secretary of State.

Dealers in motor vehicles have given the law considerable study during the past thirty days, and have seen a great many things that would cause the motor car people generally a great deal of trouble if carried out literally.

One of the things which has been of especial interest is the matter of having licenses on new cars that are being taken from the freight sheds or distributing points to the dealer's place of business. In cases where dealers want to move several cars at one time, it would work a considerable hardship on them to have each car equipped with number tags, as it would mean the buying of several additional licenses that would not be needed except on these occasions.

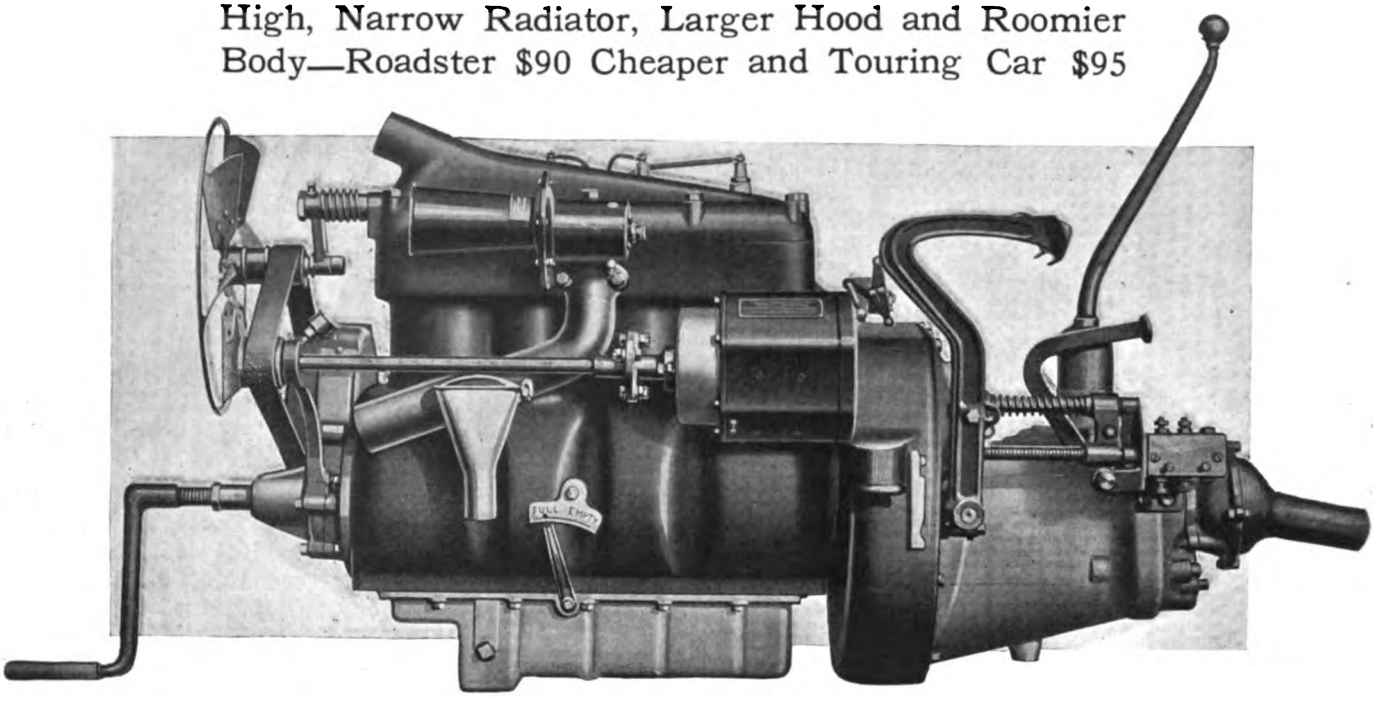
Secretary of State I. M. Howell, has advised that in his judgment it is not the intention of the law to require all cars to be tagged with State numbers when they are operated in such a manner if they are kept all together and the front and last car carries license tags in the regular way.



Chalmers 6-40 five-passenger car for 1916 which sells at $1,275

1916 Maxwell Larger—Price Lower

High, Narrow Radiator, Larger Hood and Roomier Body—Roadster $90 Cheaper and Touring Car $95



Left side of Maxwell four-cylinder block power plant for 1916. Note new oil gage and also fan drive

A BIGGER, better-appearing car at a reduced price is the offering of the Maxwell Motor Co. for 1916. The fitting of a high, narrow radiator, a larger hood, a more roomy body and the incorporation of a number of detail refinements in chassis and in comfort particulars have increased the value of the car to the purchaser while at the same time the Maxwell company has made a price cut of $90 on the roadster and $95 on the touring car. For 1916 the Maxwell touring car is $655, the roadster is $635.

While built upon the same chassis of 103-in. wheelbase, the new Maxwells appear larger than their immediate predecessors. The higher radiator, the changed body lines, and the rounding of the bodies into fuller lines, have produced this effect. The hood has been raised and the body where it meets the hood has been rounded out.

While the size of the motor has not been altered, greater port area has resulted in an increased power. Other changes in the unit power plant construction include the complete inclosing of the clutch and flywheel instead of the former construction whereby there was a yoke passing around the open flywheel and supporting the gearset. An entirely new feature is the running of the cone clutch in oil. The housing is designed to be oil tight, and thus the clutch is constantly bathed in the lubricant, which cushions its engagement.

In the Maxwell design of clutch, a woven asbestos fabric is used as a facing for the cone, thus the oil does not harm it in any way. It is probable that leather could not be used with an oil bath of this kind. A slightly heavier adjustable clutch spring is used with the new oil-bath construction. The cone is now made of cast aluminum instead of pressed steel, so that the unit is really lighter than before.

Oiling More Positive

Instead of introducing the oil at the front trough, and then allowing it to find its way through ducts to the other troughs, the new method is to introduce oil into each trough individually, making a more positive arrangement. A supply pipe runs along the inside of the crankcase and there is a lead to each trough. Along with this change a new aluminum base is now fitted which replaces the former pressed steel base and acts as the reservoir. An oil gage on the side of the crankcase is another new fitting. It operates by having a float-controlled pointer indicate the level. Another refinement is the fitting of a combination breather and oil filler on the left side. Although this breathes downward, the filling is from the top, and hence any oil that might be thrown out from the crankcase is sent to the drip pan instead of spraying over the engine.

The engine is of the detachable-head type, and this year an improved form of head is fitted. It is split higher up, and carries the water outlet connection as an integral part.

Power Plant Features

Reviewing the general features of the Maxwell power plant, the engine retains its bore of 3⅝ in. with stroke of 4½ in., and it has a S. A. E. rating of 21.1 hp. The dimensions give a displacement of 185.8 cu. in., and the stroke-bore ratio is 1.24.

Cylinders and the upper part of the crankcase are integral, making for a rigid construction. Valves and manifolding are on the right, as is also the Simms high-tension magneto. The two-bearing crankshaft is exceptionally large. Two bearings support the camshaft also, and the front gears are spiral bevels.

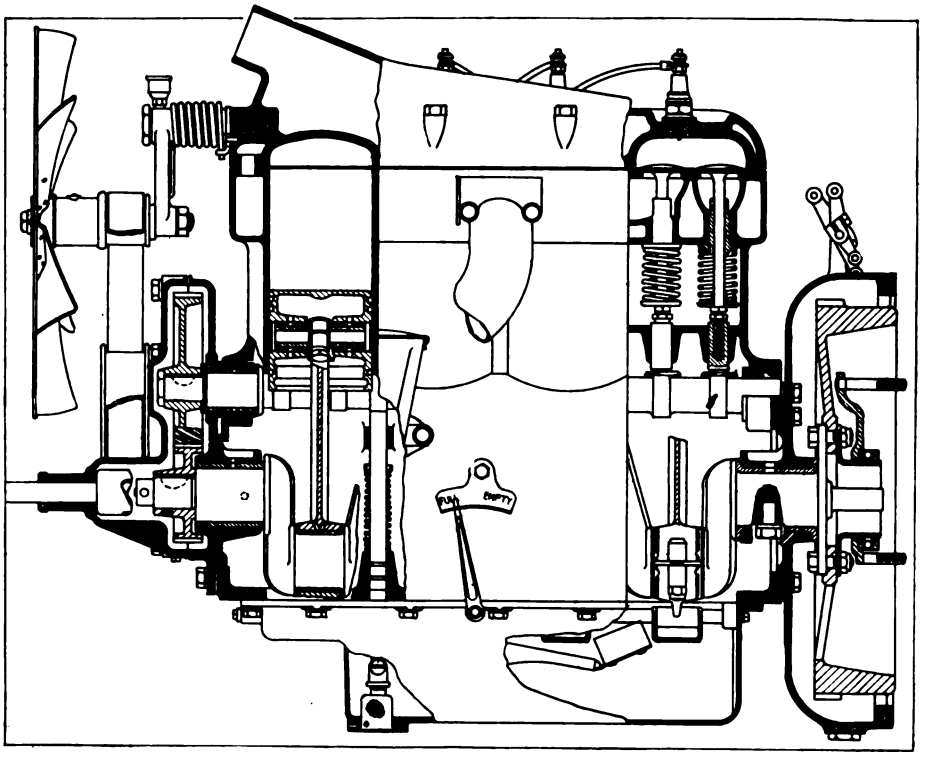
Principal Motor Dimensions

The bearing sizes and valve dimensions follow:

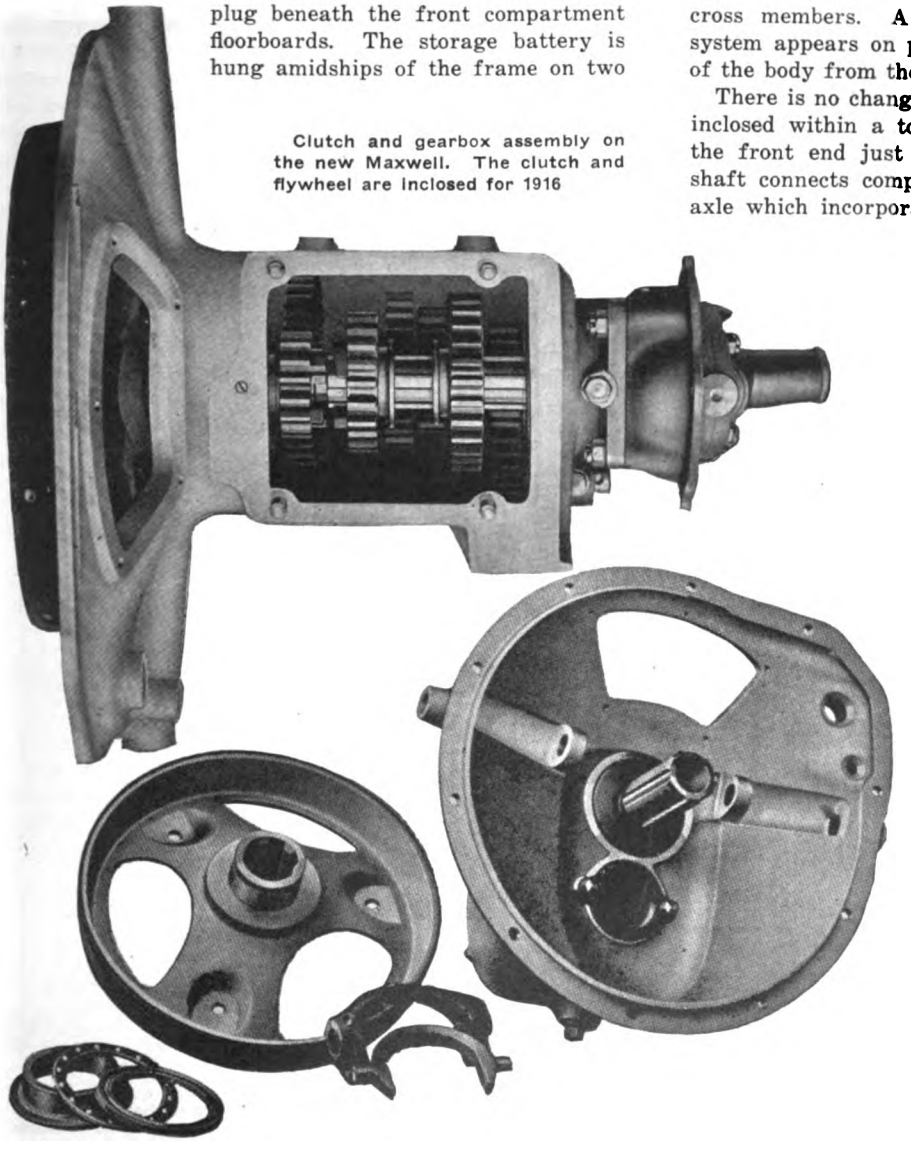
Front main bearing: 1⅞ by 2½ inches.
Rear main bearing: 1⅞ by 2 13-16 inches.
Connecting-rod lower bearing: 1⅞ by 1½ inch.
Camshaft front bearing: 1¼ by 1 13-16 inch.
Camshaft rear bearing: 1¼ by 1⅜ inch.
Valve diameter: 1 9-16 inch.

The Simms-Huff motor-generator unit is carried on the rear of the engine, and the one new feature is in the complete housing of the gearing which connects with the flywheel for starting. Driven as a generator, the unit is run by a shaft, but as a motor, it gears with flywheel teeth. Operating on a 12-volt current, the motor turns an average engine at about 100 r.p.m., although this will vary with the weather. Drive for the generator shaft is by a belt, which passes over three pulleys. The driving pulley is placed on the outward extension of the magneto shaft, and it passes over the fan pulley as well as the generator shaft pulley. Tension is kept constant in the belt by a spiral spring attached to the arm which carries the fan and its shaft and pulley. This bracket is carried by the cylinder head, and the spring holds the pulley up against the belt with sufficient force to maintain a good drive for both fan and generator with little or no slip. It makes a practically noiseless assembly.

There is a commendable refinement in connecting the wires on the body with those on the chassis by a junction plug beneath the front compartment floorboards. The storage battery is hung amidships of the frame on two cross members. A diagrammatic illustration of the new system appears on page 150. It greatly facilitates removal of the body from the chassis.



Part section through Maxwell four-cylinder block motor for 1916



Clutch and gearbox assembly on the new Maxwell. The clutch and flywheel are inclosed for 1916

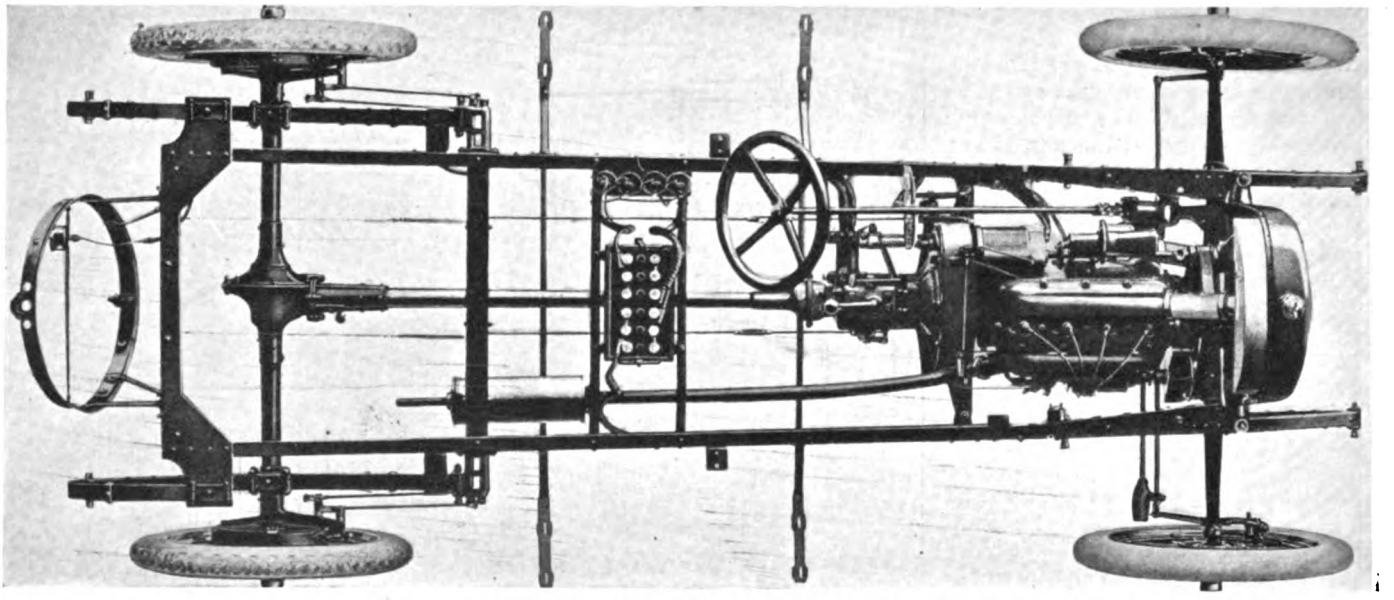
There is no change in the drive system. The driveshaft is inclosed within a torsion tube and there is a universal at the front end just back of the three-speed gearbox. The shaft connects compactly to the three-quarter floating rear axle which incorporates five Hyatt spiral roller bearings in its construction. There is one bearing under each wheel, one carrying the pinion and one on either side of the differential unit. Ball thrust bearings are used in conjunction with the Hyatts in the latter three positions. The axle shafts are of nickel steel, and are housed in tubes of seamless steel which rivet to the malleable iron differential housing. An axle ratio of 3⅝ to 1 is used.

Springing is continued as in 1915, with three-quarter elliptic rear springs 40 in. in length, and front springs 32 in. The rear pair is fixed at the front to transmit the drive, and attaches to the axle on a rocking seat, giving unrestricted action.

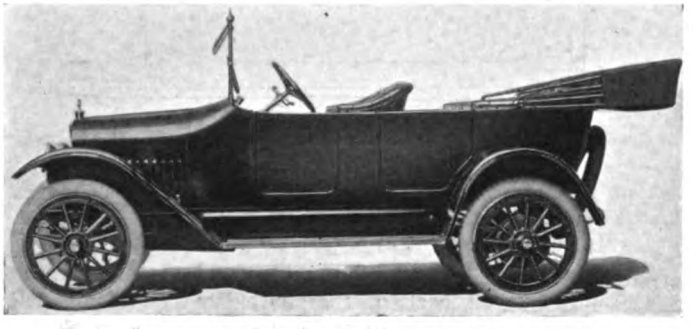
By tapering the frame, it gives good support to the body along the entire length, the rear width being 33 7/16 in. as compared with 28 in. at the front. There are three cross members, the rear forming a mounting for the upper end of the springs, while the tire carrier is also attached to it.

Tires are 30 by 3½ with non-skids in rear. A new feature on the 1916 cars is the use of demountable rims instead of the straight clincher type.

Aluminum-covered running boards are used instead of corrugated metal. On the floor of the front compartment,



1916 Maxwell chassis, showing tapered frame with cross member for tire carrier and giving an idea of the new radiator



The 1916 Maxwell touring car which sells for $655

linoleum is also used in place of the former rubber matting. Non-rustable metal edging is used to hold down the edges of the new covering for these parts, making a very neat job.

More rigid supporting of the headlights is secured by bracketing them to the fenders instead of by vertical supports from the frame. A noticeable change is the fitting of a well-arranged instrument board with speedometer and gages set flush with its surface in contrast with the former portruding attachment. The electrical connections are all brought to one unit which is removable so as to readily reach the terminals. In the center of this unit there is a plate held by a spring. This exposes the fuses, making it very convenient to replace them.

Body Longer and Wider

The body is widened and lengthened so that more leg room is provided as well as 3 in. greater width in the seats. There is 29 in. leg space in the front and 28 in the rear of the touring model. Pockets have been put in all four doors, which are considerably wider. Accelerator and starter pedals have been farther separated.

Points that do their part in adding to appearance are the louvres in the hood, the improved two-piece windshield which has substantial side supports to carry the front of the one-man top—also a new feature—and the domed fenders which are made unusually strong.

The gasoline tank has been somewhat enlarged so as to hold 10 gal. A conveniently-located sediment cup on the right under the hood strains the fuel going to the carbureter and is fitted with a shut-off cock.

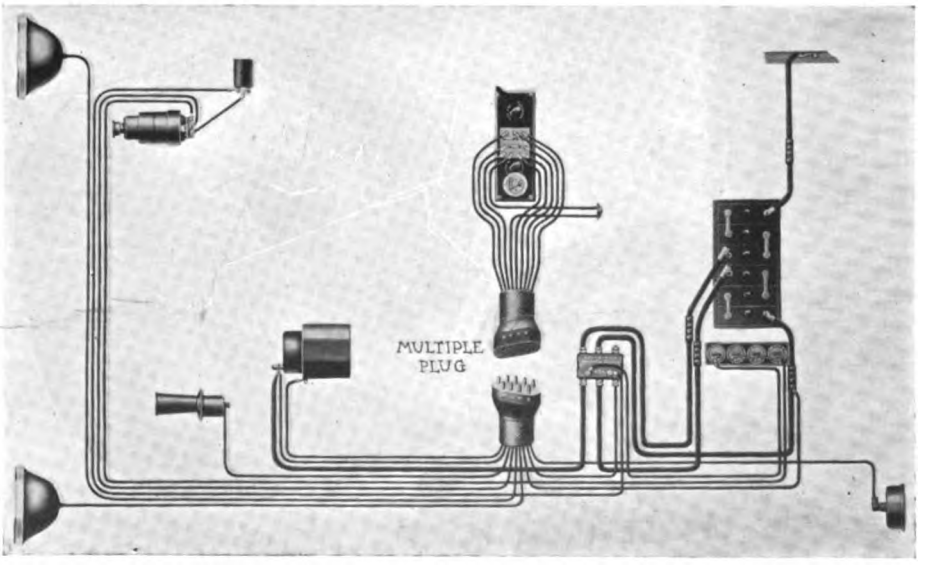
In addition to the open body models already mentioned, Maxwell offers a five-passenger permanent-top convertible-body type at $935, a six-passenger town car at $915, and a two-passenger cabriolet at $865. The first-mentioned is fitted with sash in the sides which may be slipped down into compartments in the body when desired, leaving all open with only the top permanent.

—

Regulate Truck Size in Ohio

CLEVELAND, OHIO, July 18—The weight and speed of motor trucks are to play an important part in the new laws now being enforced on city streets and county roads. The weight limit on any stone, brick or macadamized road is 3,400 lb., with vehicles having a tire less than 3 in. wide.

Vehicles with a greater total weight will not be allowed to travel over county roads without permission from the board of county commissioners. Vehicles or contrivances having flanges or lugs are prohibited.



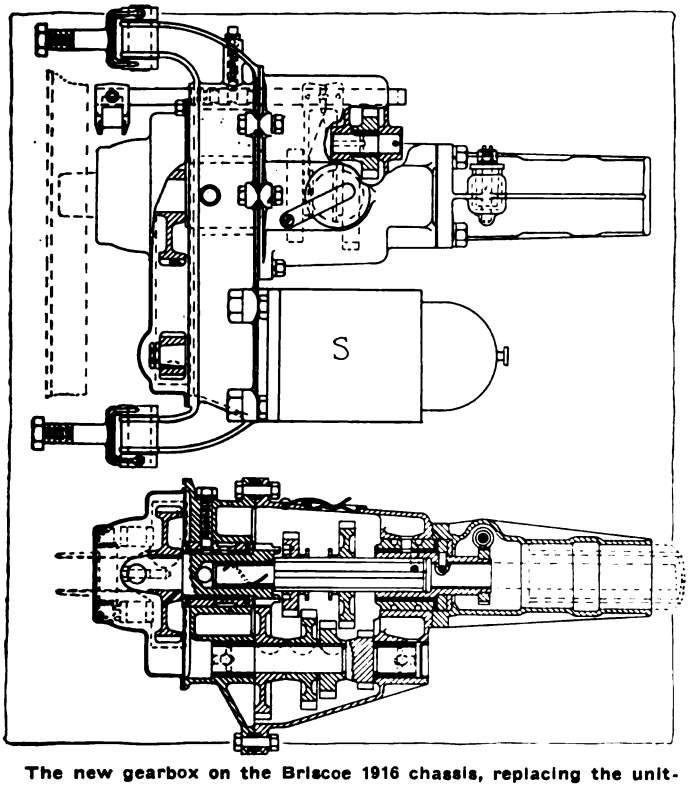
New Maxwell wiring system permitting easy removal of body from the chassis

Briscoe Eight and Four in Same Chassis

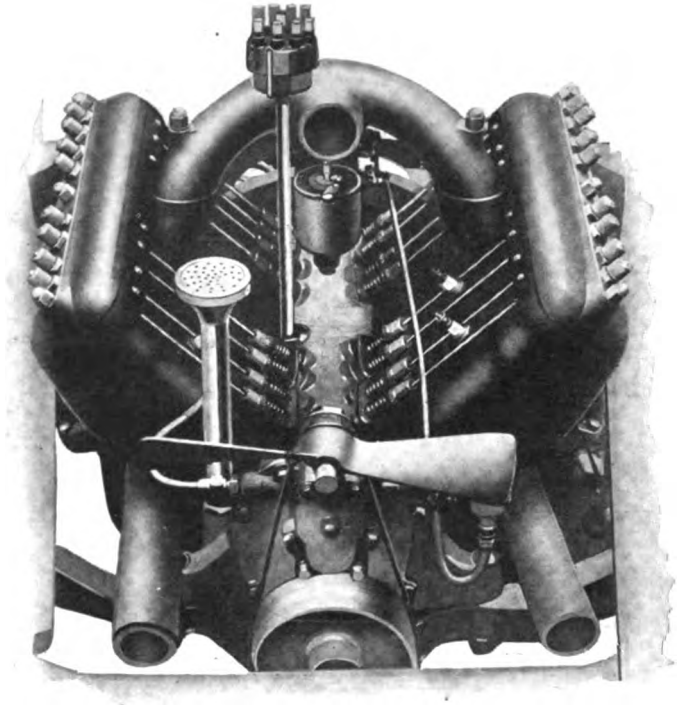
Eight Is Ferro 3 by 3 1-2 and Four a New Briscoe Design 3 7-16 by 5 1-8—Gearset Reconstructed To Render Motors Interchangeable—New Rear Suspension by Cantilevers—Two Headlights for 1916

THE 1916 season will, with a few companies, be the proving out as to the desirability of fitting two different motors on the same chassis, the chassis design being such as to make this possible at a nominal increase covering a larger motor. As announced in these columns some weeks ago, the Briscoe Motor Co., Jackson, Mich., has such a program and is prepared to furnish either a four-cylinder or eight-cylinder motor in the same chassis, giving a buyer the option of using the four-cylinder motor for thirty days and if at that time he decides on an eight he can secure the same at $200 additional, the Briscoe company taking back the four-cylinder motor and installing the eight. The four-cylinder motor is a brand new design and the eight-cylinder motor is built by the Ferro Machine and Foundry Co., Cleveland, Ohio, and characterized by having valves in the head and having the eight cylinders and upper half of the crankcase formed in one casting. This motor was exhibited during the recent New York show and has been undergoing development ever since. The four-cylinder motor which the Briscoe company fits is 3 7/16 by 5⅛. It is claimed to give 38 hp. at 1700 r.p.m. It is an L-head block design with detachable cylinder head and valve stems and springs inclosed.

The eight-cylinder motor is a conventional V-type design with cylinders 3 by 3½ giving a piston displacement of 198 cu. in. as compared with 190.4 cu. in. on the four-cylinder. This motor, like the four, has detachable cylinder heads.



The new gearbox on the Briscoe 1916 chassis, replacing the unit-with-motor construction, due to the necessity for interchangeability of the eight and four-cylinder motors in the same chassis. S is the motor-generator



The valve-in-the-head Ferro motor used in the 1916 Briscoe eight-cylinder model. This engine has a bore of 3 and a stroke of 3½ in., giving a piston displacement of 198 cu. in.

Owing to offering either eight- or four-cylinder motors in the same chassis, the Briscoe company has now mounted the gearset as a separate unit in the middle of the chassis whereas formerly it has been in unit with the motor. The substitution of one motor for the other is hence a matter of connecting the shaft between the clutch and the gearset insofar as the driving elements are concerned.

Two Headlights Instead of One

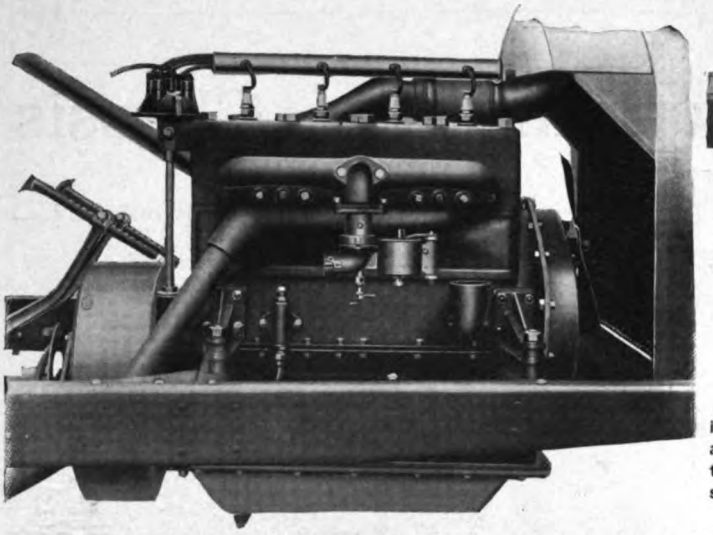
Externally, the 1916 Briscoe car is quite different from the 1915 model chiefly in that two headlights are used in place of the single light incorporated in the radiator, which scarcely met the requirements of certain states where two lamps are compulsory equipment.

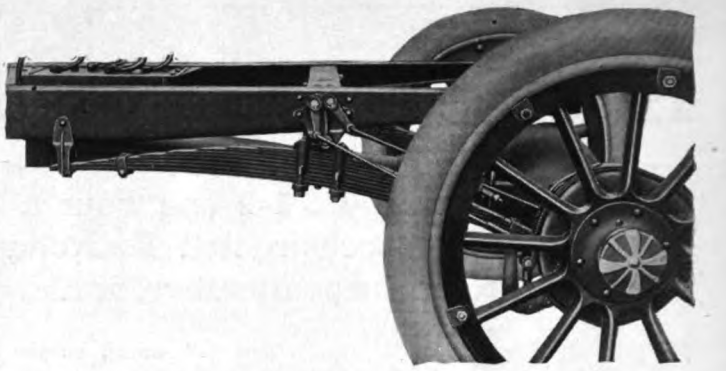
Domed fenders add to the general appearance, and they have been more rigidly fastened, by attaching them directly to the body in place of the previously used method of mounting them by brackets to the frame. Obviously there is less chance for rattle and wabbling by this method of construction.

The four-cylinder machine is so radically different from that of last season that it may rightfully be called a new job throughout. The scheme is to furnish either engine the customer desires, charging $750 for the car with the four and $950 with the eight.

New Cantilever Suspension

The new body gives 3 in. more leg room in the rear, and a new rear suspension supersedes the semi-elliptic design of 1915 models. It is of a nice cantilever type, and makes an exceedingly easy riding car. The wheelbase has come in for





Left—Manifold side of the new four-cylinder Briscoe motor, showing carbureter and distributer mounting. Note combined intake and exhaust manifold. Right—Cantilever rear suspension used on the 1916 Briscoe chassis. Note that the lower end of the spring is secured below the axle housing

a 7-in. increase to 114 in., and along with the general enlargement of the car, tires have been increased from 30 by 3½ to 32 by 3½ size. Control pedals are now adjustable; and the double internal expanding brakes have been replaced by the more usual internal expanding emergency and external contracting service sets.

Summed up, the new Briscoe four is a larger and more powerful car than the 1915 model, so that it is more value for the money. The motor is an entirely new design with a bore of 3 7/16 in., as compared with the 3⅛-in. bore of the previous engine. The stroke is the same—5⅛ in. Another important difference is the separation of gearset and engine, the former now being located amidships in contrast to the former unit power plant construction.

The eight-cylinder Ferro engine adheres very closely to the design as brought out the early part of this year. The valves are overhead, with rods running up from the single camshaft in the center of the V. Cylinders have a bore of 3 in., and a stroke of 3½ in., giving a piston displacement of 198 cu. in.

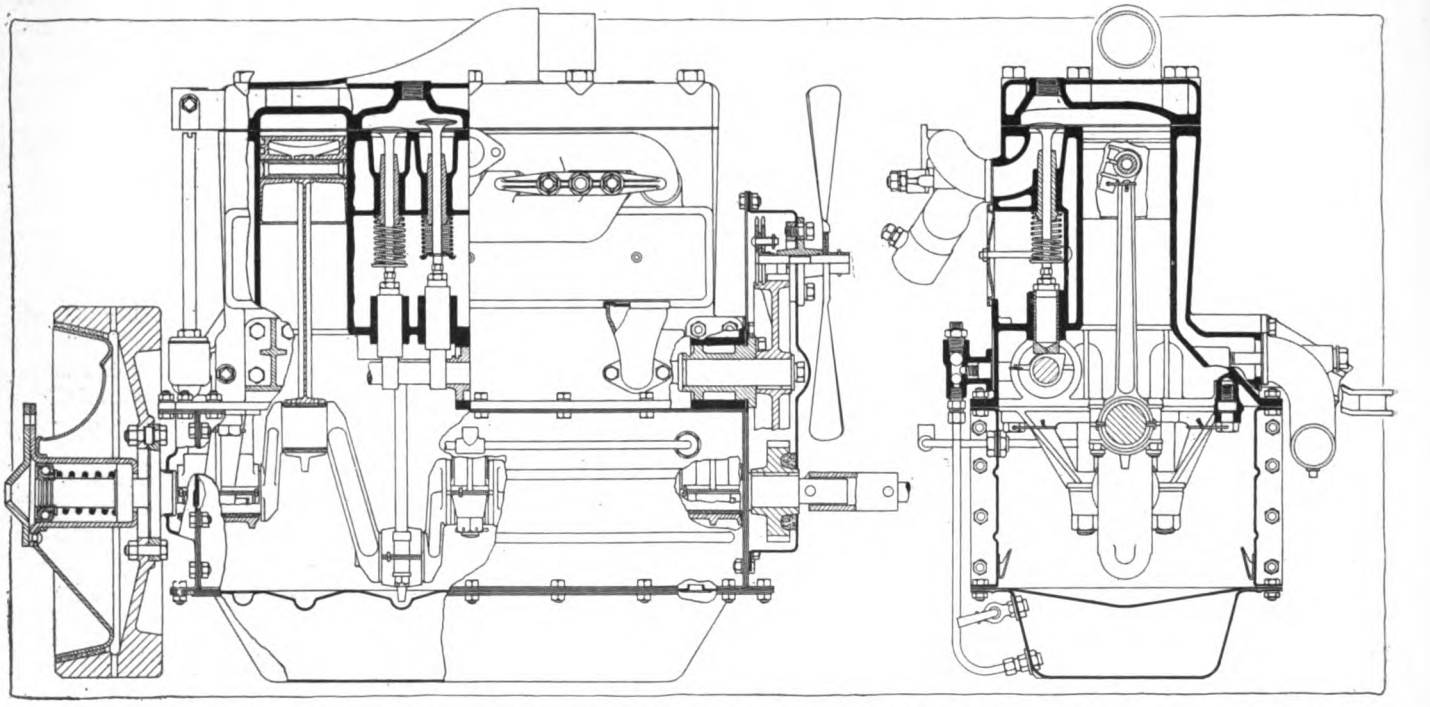
In this engine, the two blocks of four cylinders are set at the usual 90 deg., and the upper half of the crankcase is made integral with the cylinders. Thus, their eight cylinders and upper case are cast as one piece, and greater rigidity is claimed for the design.

Single Camshaft Used

Sixteen cams are used on the single camshaft, mounted at the center of the V, giving a cam for each valve and making possible a simple duplicate four-cylinder timing. That is, No. 1 cylinder on the right is followed by No. 1 left, and so on. There is also another special feature of the engine, namely, the use of hot-pressed steel rocker arms for operating the valves. These are so pivoted in the top of the cylinder heads on ball joints that adjustment is made through the use of knurled nuts protruding through the top of the cylinders. Thus, in order to take up any play between valve rod and rocker, it is a simple matter to loosen the lock nut and turn the knurled adjustment screw until the proper clearance is obtained, the location of these being very convenient on the top of the cylinder blocks.

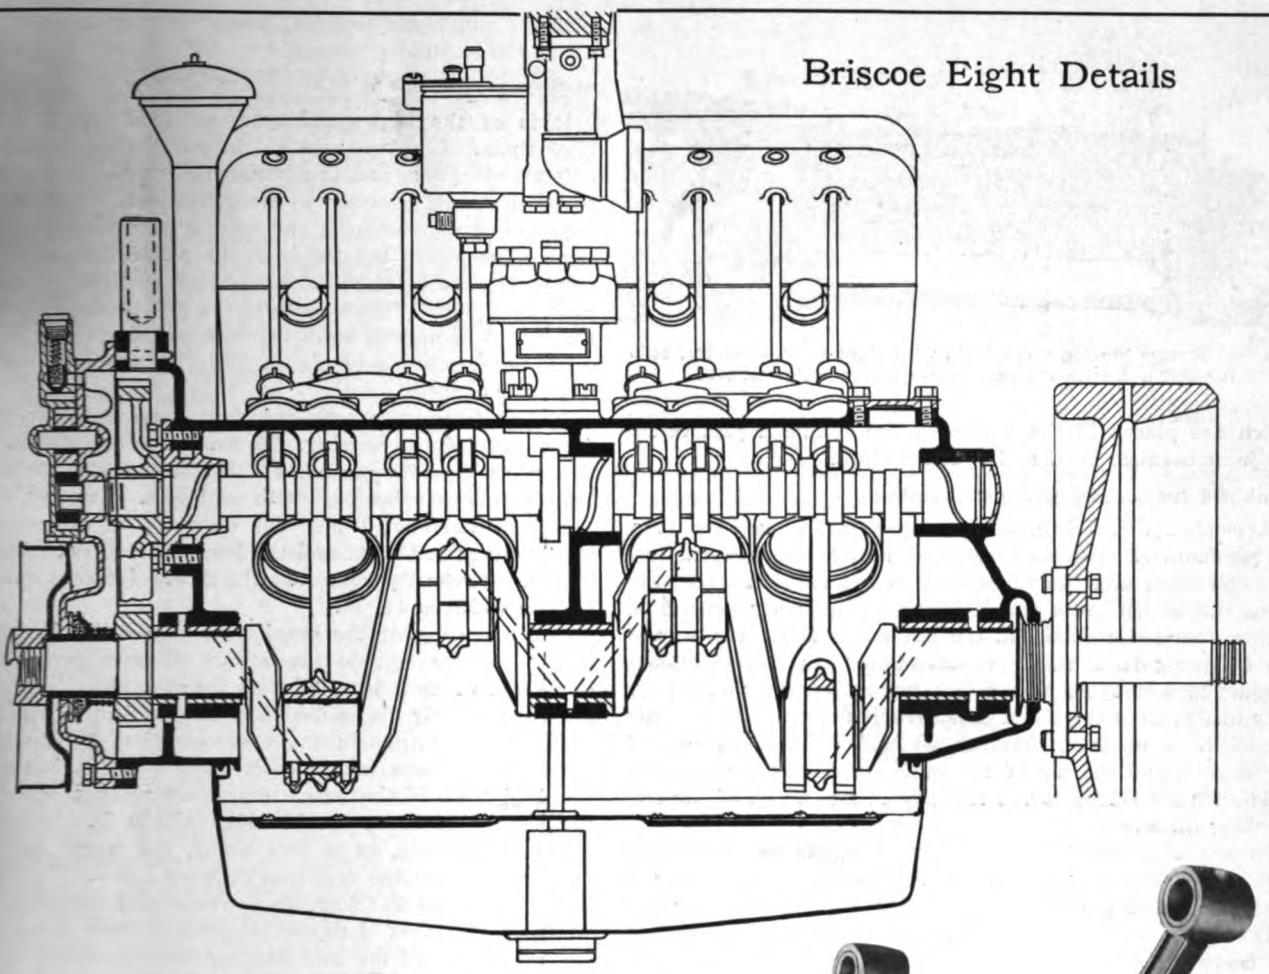
Cylinder Heads Detachable

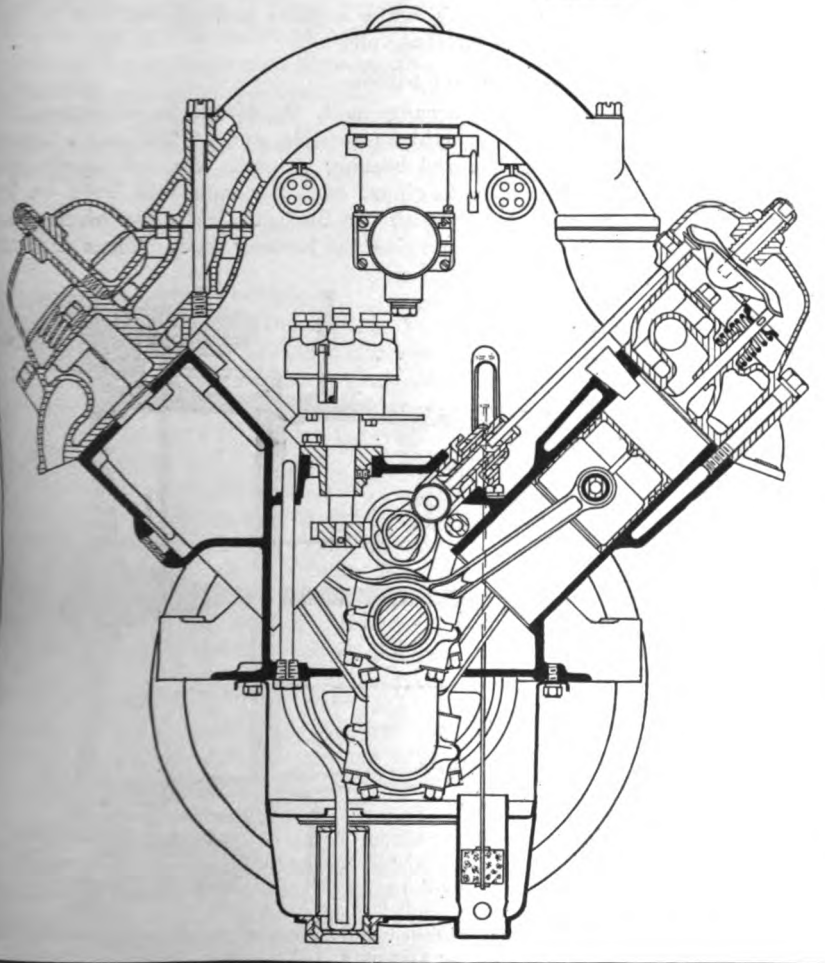
The cylinder heads are detachable, their removal giving access to the pistons. These heads carry all the valve mechanism, the water outlet connections and everything at the top part of the cylinders with the exception of the spark plugs

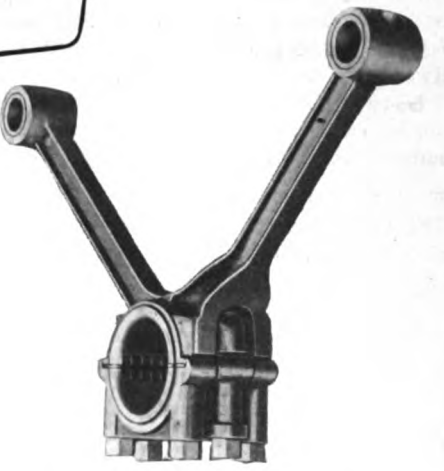


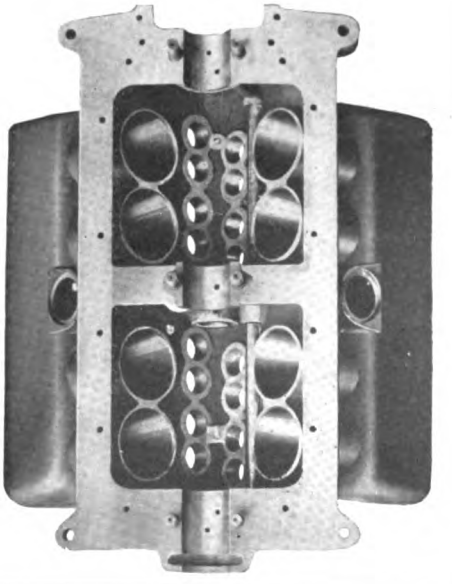
Longitudinal and transverse sections through the new four-cylinder Briscoe motor which has combined intake and exhaust manifolds, detachable cylinder heads, etc.

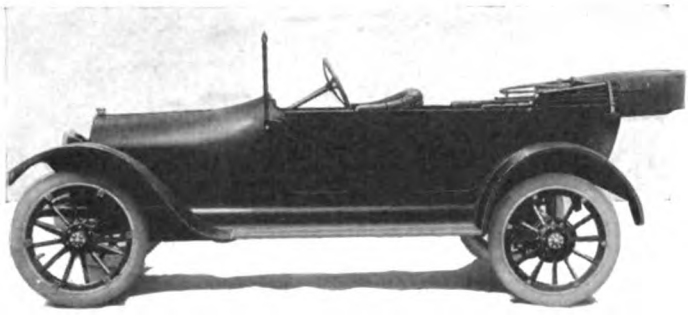
Briscoe Eight Details











The 1916 Briscoe touring car, which, with eight-cylinder motor, sells for $950 and with the new four-cylinder design at $750

which are placed in the V-side of the cylinders just below the joint between head and cylinder block.

Combined Intake and Exhaust Manifold

A combined fuel intake and water outlet manifold is a unique feature. The water passage really surrounds the inner fuel pipe, and the connection to the radiator is at the front side of the cross double-duty manifold. By the use of such a concentric manifold, the hot water circulates around the incoming fuel, aiding vaporization. As thermo-syphon cooling is employed, this outlet water construction works very nicely, since there is a considerable distance between the top of the combustion chamber, which is the hottest part of the engine, and the top of the radiator, due to the V form. This adds materially to the rapidity of movement of the circulating water.

In the attachment of the connecting-rods to the crankshaft, the forked design is used. That is, one rod has a yoked end, and the other rod for the opposite cylinder fits between the arms of this yoke. So as to make adjustment of the caps as easy as possible, the bearings have been split on a horizontal plane, instead of at right angles to the centerline of the rod.

The New Four-Cylinder Motor

With practically nothing in common with the previous Briscoe motor, the new four is an extremely smooth-appearing design, with the cylinder block and upper half of the crankcase in one piece. The head is detachable, and valves are located on the right and very compactly inclosed. It is suspended at four points in an unusual manner by four brackets which are separate pieces bolting to bosses on the sides of the cylinder casting.

38-Hp. at 1700 R.P.M.

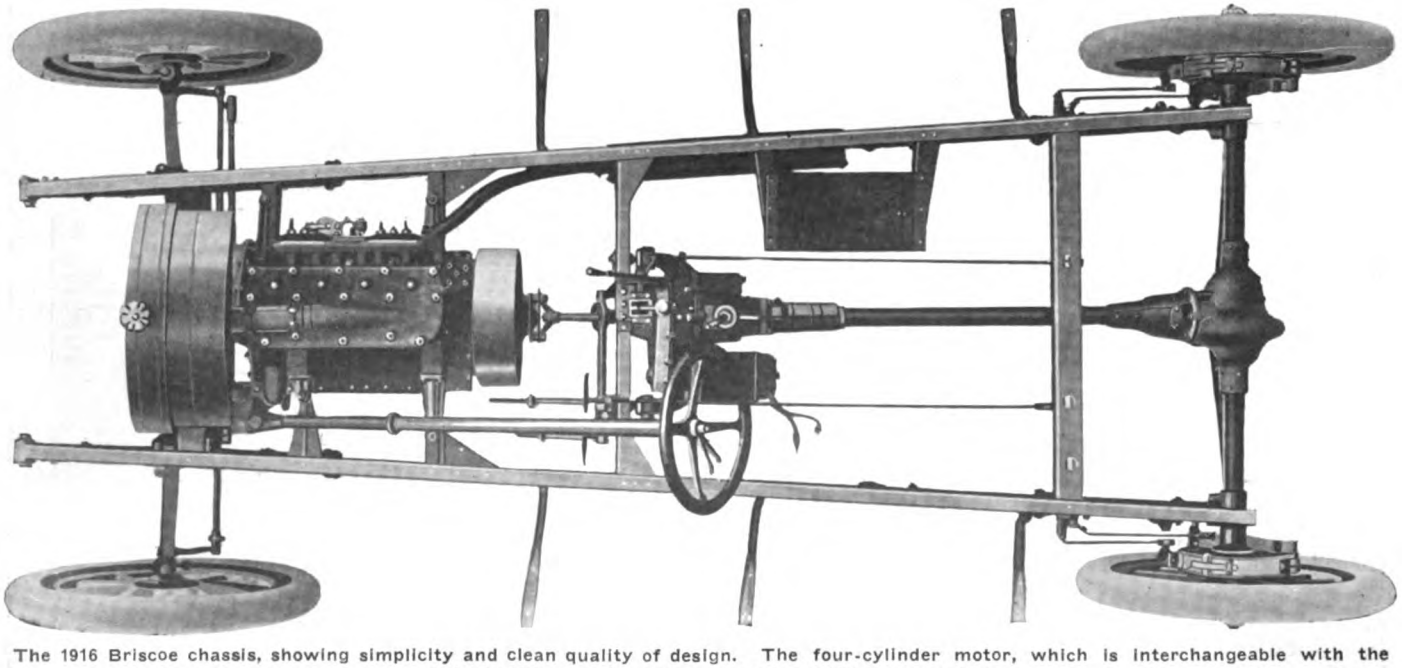
It is of the high-speed type, with 38 hp. produced at 1700 r.p.m. Light pistons aid in permitting of high speed without vibration, and in addition the crankshaft is of large proportions and mounted on three bearings. The connecting-rods are of regular form and forged from chrome-vanadium steel. The piston bearing is in the piston bosses, the upper end of the rod being split on one side, and the pin clamping in it by a bolt. Two bolts hold the cap to the lower end of the rod. The pistons are fitted with two rings, and the heads are concaved, so as to give a desirable semi-spherical combustion chamber.

A few features of the specifications are 1¾-in. valves; front crankshaft bearing, 1⅛-in. diameter, 2¾-in. long; center crankshaft bearing, 1 9/16 in. diameter, 2 in. long; rear crankshaft bearing with a 1⅝-in. diameter, 3¼ in. camshaft diameter, 1 in. The diameter of the connecting-rod bearings is 1⅝ in. and the length is 1¾ in., there being 9⅞ in. between the centers. The flywheel diameter is 14 in. and its width is 4¼ in.

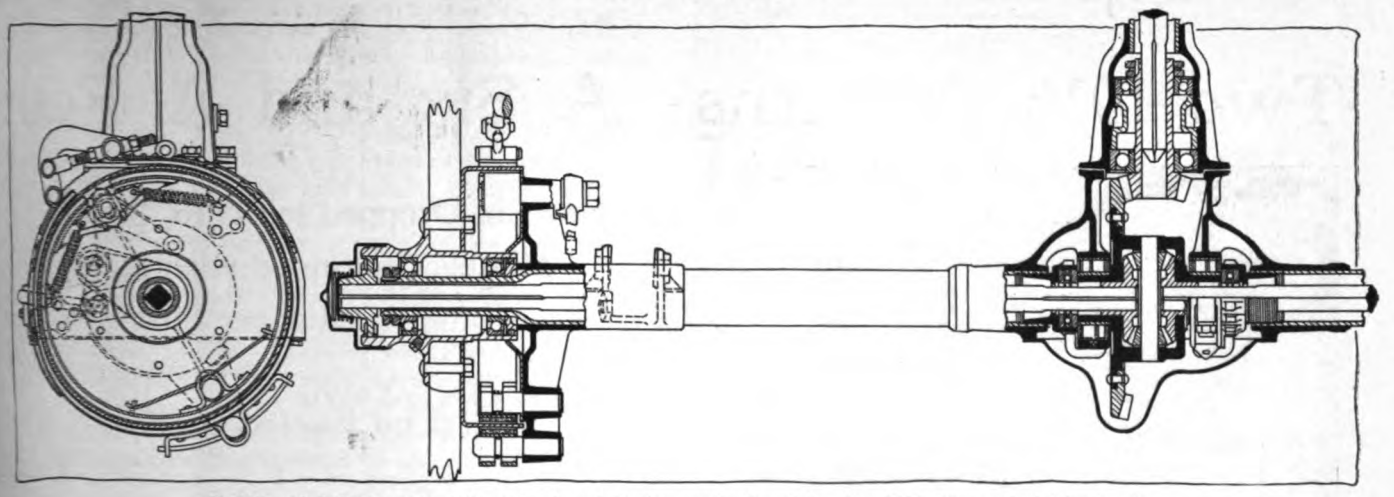
The mounting of the crankshaft is peculiar in that separate brackets bolt to the bottom of that portion of the crankcase which is integral with the cylinders. These brackets have exactly the same function as the usual integral crankshaft bearings in the crankcase, but the construction is lighter, because with equally rigid support, less metal is required than if the entire crankcase were extended down far enough to carry the bearings within it. This is especially true where, as in this motor, the upper part of the case is a part of the cast iron cylinder block. To extend the heavy metal all the way down would add materially to the weight. As it is designed, a pressed-steel cover acts as the lower part of the case housing the crankshaft and these bearing brackets, while another piece closes the bottom and acts as the oil reservoir.

Engine Light but Strong

The whole arrangement, therefore, is designed to make the engine as light as possible, and at the same time crankshaft rigidity and bearing strength are not sacrificed. The brackets are forgings, and the caps are held on by two 11/16-in. bolts which run up to the cylinder block extension, and assist in carrying the bearing load. Thus that part of



The 1916 Briscoe chassis, showing simplicity and clean quality of design. The four-cylinder motor, which is interchangeable with the eight in this chassis, appears in this particular assembly



Details of Briscoe rear axle, wheel and brake as designed for the 1916 four and eight chassis

the crankcase which really incloses the shaft is merely a housing or cover and has nothing to do with carrying the load of the shaft.

Thermo-syphon cooling is well applied to the engine, with a 2-in. water outlet connection integral with the cylinder head. The heads are entirely water jacketed, while the jacketing of the cylinders is uniform, due to the comparatively even thickness of the space around all the cylinders. Also, the water is carried down the entire length of the cylinders, and the water inlet is at the extreme lower front side of the casting.

Friction Drive for Fan

Drive for the cooling fan is unique in that a friction means is employed. The camshaft gear face is made wide enough so that two grooves can be accommodated in the face and back of the gear teeth. These grooves receive two small steel friction disks mounted on the fan shaft. Pins carrying small spiral springs pass through the two disks and the fan shaft flange, thus maintaining an even tension of the disks upon the grooves in the driving gear. The result of this scheme of drive is a noiseless and extremely simple combination which revolves the aeroplane type of fan at the required speed for proper cooling. This mechanism as well as the front gears is all inclosed by a pressed steel front plate.

Atwater Kent Ignition

Driven off the end of the camshaft is the vertically-mounted Atwater Kent ignition distribution unit. The balance of the electrical functions are provided for by the motor-generator mounted on the left side of the gearbox. This charges the battery and lights at 6 volts, and uses 12-volt circuit for starting.

In lubricating the engine, the circulating-splash method is used. The oil is brought up from the reservoir by a plunger pump operated by the camshaft, and it is delivered through a sight-feed on the dash and thence to the oil troughs under the connecting-rods, these having dippers on their caps to catch the oil and throw it to the bearing surfaces, from which it drains back to the sump.

New Gearbox Construction

The transmission mechanism is very simple. The gearbox is really in unit with the torsion tube which surrounds the propeller shaft. The front of the gearbox has two arms which hinge to a cross member. Thus axle variation is due to road unevenness is provided for by this gearbox hinging. As the rear of the gearbox attaches to the torsion tube, there is no frame support for it except at the front.

A floating Salisbury rear axle is fitted. This has two ball bearings supporting each wheel, one on either side of the vertical centerline of the wheel. This is in contrast to the type in which a single bearing is placed directly under the wheel, and there is obviously better support and less chance for misalignment and resultant wheel wobbling. Likewise, two ball-thrust bearings carry the pinion shaft, and there are also roller and ball-thrust bearings on either side of the differential.

Full Cantilever Springs

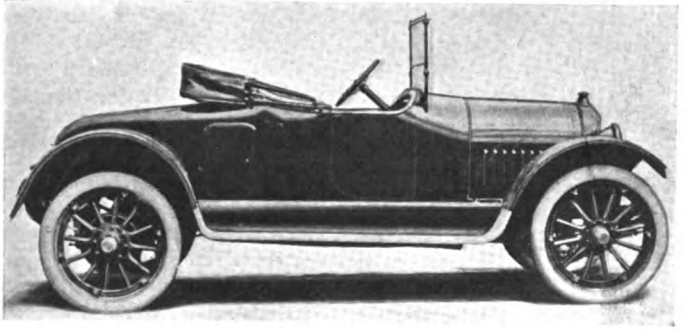
In its application of cantilever springs, Briscoe uses the full cantilever type, with trunnion mounting at the center to a frame bracket, a sliding bracket at the front, and attachment of the rear under the axle tubes. Plenty of action is afforded, due to this design. This year, bushed spring eyes are provided, making possible the elimination of grease cups.

Three Body Types

Three body types are offered, all of graceful lines. These are the touring car, three-passenger roadster and two-passenger coupé. The roadster is still styled the Clover Leaf, as the center seat is set somewhat back of the two outside ones. The coupé costs $1,000 with four-cylinder motor, and there is, of course, the same exchange proposition for the eight.

—

A New Moline-Knight Roadster Model Just Brought Out

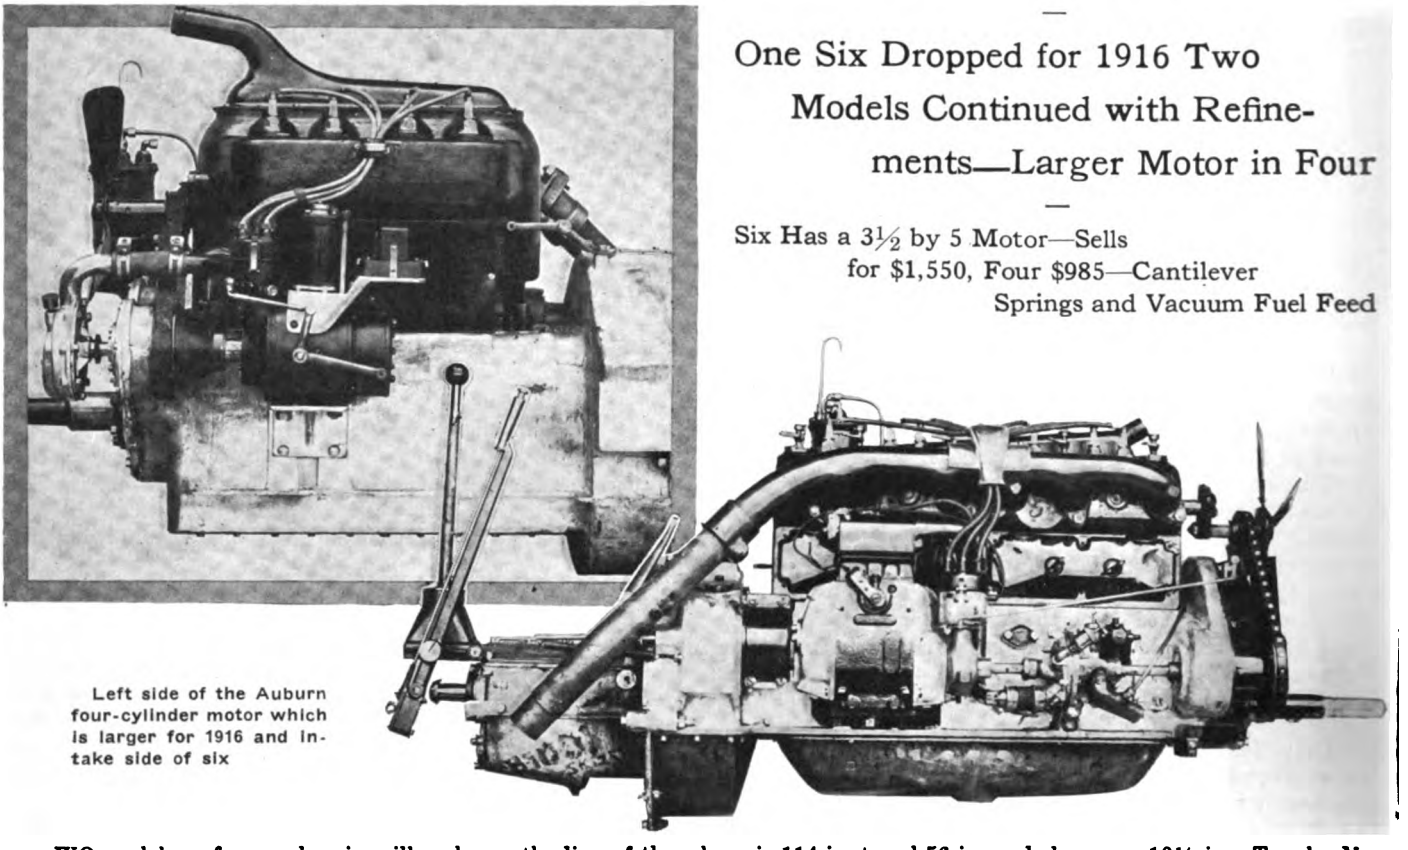


The Moline Automobile Co., East Moline, Illinois, maker of the Moline-Knight, have recently placed on the market a two-passenger roadster listing at $1,475. The new 40 horsepower roadster body is similar to its sister car, the model 50, roadster. It is mounted on the identical chassis of the present five-passenger touring model. The roadster has a large carrying capacity, the rear part of the body being divided into two compartments—one parallel with the seat and entered by an oval shaped door on the right side of the car, while the larger compartment opens from the rear. The large compartment is of such ample dimensions that it will permit the carrying of a steamer trunk, spare tires, suit cases and other luggage

Two 1916 Auburns—A Six and A Four

One Six Dropped for 1916 Two Models Continued with Refinements—Larger Motor in Four

Six Has a 3½ by 5 Motor—Sells for $1,550, Four $985—Cantilever Springs and Vacuum Fuel Feed



Left side of the Auburn four-cylinder motor which is larger for 1916 and intake side of six

TWO models, a four and a six will make up the line of the Auburn Automobile Co., Auburn, Ind., for the 1916 season. For 1915 there were three, a four, and two sixes. For this season the larger of the two sixes has been dropped, and the other continued along with the four. No radical changes have been made in the new models, although some of the alterations are of importance including the introduction of cantilever springs, vacuum gasoline feed with rear tank, flush doors, invisible hinges, flush door handles, roomier bodies and disappearing auxiliary seats in the seven-passenger car.

New Four Has Larger Motor

The four-cylinder model which last season was known as the 4-36 is now known as the 4-38 and in place of the 3.75-in. bore of 1915, the 1916 car has a bore of 3.875 and a stroke of 5 in. the latter figure being the same as for the 1915 season. The stroke bore ratio is 1.29 and the S. A. E. rating 24. A claim of 38 hp. on the brake is made by the manufacturers. As would be expected in a T-head design, the valves are large having an outside diameter of 2 3/16 in. with a port opening of 2 in. clear. The valves are interchangeable with cast iron heads on nickel steel stems.

Other features of the motor are a three-bearing crankshaft, three-bearing camshaft, chrome-nickel steel piston pins and a special patented lubricating system. This is a splash design with two overflow basins located in the lower part of the crankcase. In addition to the regular splash arrangement, there is cast integrally with the upper half of the crankcase an oil pocket over each main bearing. These are kept full, continuously providing oil to the crankshaft.

The timing gears are spirally cut and the generator is mounted on the pump shaft. The starting motor is installed back of the flywheel housing and the pinion meshes with a hardened ring gear on the rim of the flywheel. The wheelbase is 114 in. tread 56 in. and clearance 10½ in. Two bodies are fitted on this design, a two-passenger roadster and a five-passenger touring, both selling at $985, fully equipped.

Six Different in Design

Model 6-40 A is the only six-cylinder car listed by the Auburn company this year. It is an entirely different design from the four having its six block-cast cylinders L-head instead of T. It uses the three-point suspension system in connection with the unit power plant. The cylinders are cast from reverberatory air-furnace iron and then rough bored finish bored and ground. The pistons are cast from the same grade of metal as the cylinders and are fitted with three diagonally split, concentric expansion rings. The rings in the four are eccentric. Oil grooves are turned on the outside of the piston for collecting and distributing the oil over the inside of the cylinders. Piston pin is of annealed steel tubing, hardened and ground, and held stationary in the piston bosses by means of a simple locking device. The bearing surface is a long, large bronze bushing which is pressed into the connecting-rod.

I-beam connecting-rods are employed made from 0.35 carbon steel, drop-forged and heat treated. The connecting-rod caps are held in place by nickel-steel bolts properly secured by a locking device. The camshaft is drop-forged from carbon steel in one piece. The shaft runs in white bronze bushings and the valve pushrods are mushroom design special steel.

Three-Bearing Crankshaft

The crankshaft is carried on three main bearings. It has a special thrust arrangement in the form of flanges on each side of the center main bearing. The timing gears are helically cut and the timing set is made up of a crank, cam and pump shaft gear.

An ample size flywheel is bolted to a flange which is drop-forged integrally with the crankshaft. To this it is fastened by six bolts. A leather-faced cone clutch engages with the flywheel and transmits the drive to a gearset providing three speeds forward. These gears are drop-forged from nickel steel and carried on annular ball bearings. From the gearset the drive is taken to the rear axle by a shaft fitted with two universals. The torsional strain on the shaft is obviated by the use of a double tube torque arm, the front end of which is spring-mounted.

Other specifications of this car give the wheelbase as 126 in., tread, 56 in., clearance 10½ in., tires 34 by 4 and body capacity seven and three passengers. The two auxiliary seats in the tonneau of the seven-passenger car are large and are out of the way when not in use, folding back into the rear of the front seat. Full equipment is furnished with both bodies and the price is the same for each, $1,050.

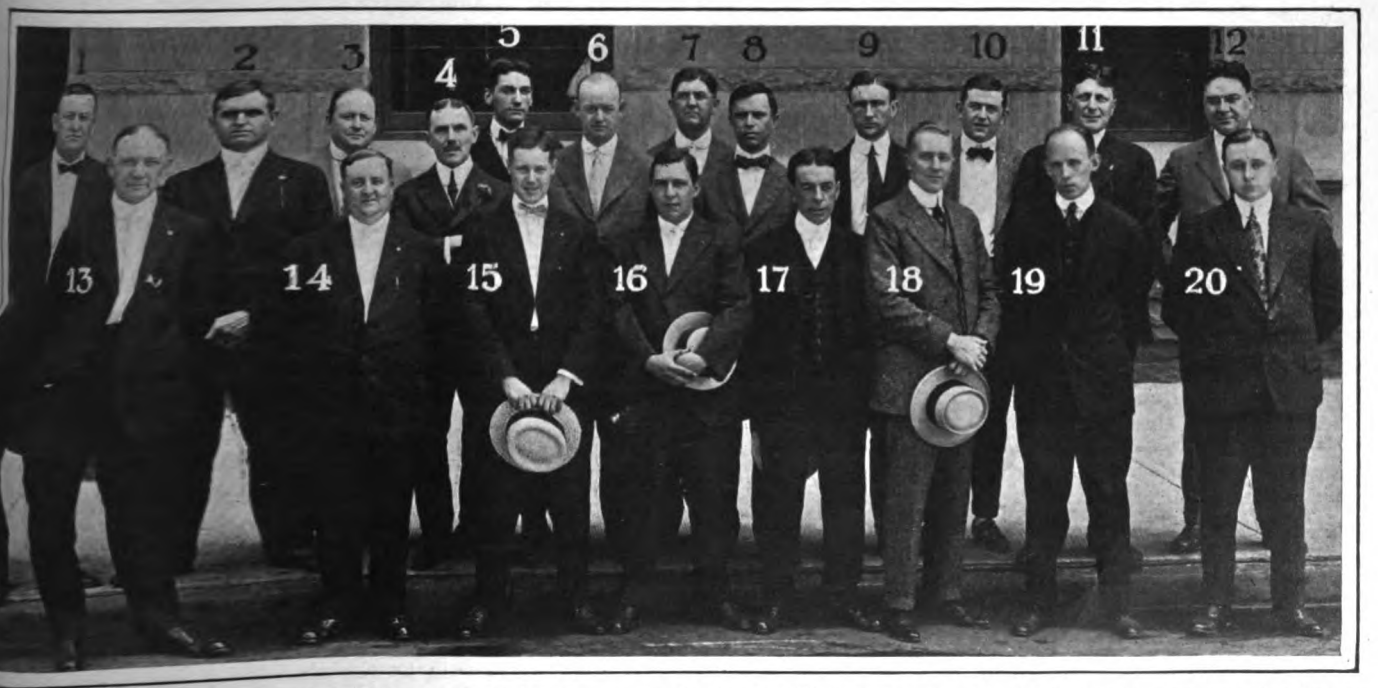
Fifth Avenue bus equipped with safety fender to guard against pedestrians walking into rear wheels

Safety Fenders for New York Buses

NEW YORK CITY, July 19—Long wooden safety fenders have been hung beneath the bodies of all the motor buses operated by the Fifth Avenue Coach Co., on Fifth Avenue, Riverside Drive and other thoroughfares of New York City. The fenders are hung on either side of the buses between the front and rear wheels and curved outward toward the rear so that the rear wheels of each vehicle are thoroughly protected. The fenders are shown in the illustration herewith.

It has been noted for some time past that the majority of accidents to pedestrians in the streets of both New York and London have been those in which the rear wheels have done the damage. It has been a peculiar fact that people wait for the front wheels of the bus to pass them and then heedlessly walk into the path of rear wheels. With the installation of the fenders it is believed that accidents of this kind will be eliminated. This will, it is hoped, eliminate a large part of the few accidents which do occur, as the statistics kept by the Fifth Avenue Coach Co. show that there is only one pedestrian injured to over 1,500,000 miles of service.

One of the interesting phases of the installation of the fenders was the shop work in connection with it. It cost the company $7.50 per fender for labor and material alone and this work was done on the company's own initiative as its safety record has not been criticised. It was desirable that the full fleet of vehicles should appear upon the streets with fenders attached on the same day. With this in view, everything was in readiness for the installation when the crews brought in their buses late Saturday night, July 17. A corps of mechanics was on hand and the fenders, fully assembled, were piled at convenient points nearby. As each vehicle rolled in, it was quickly attached by the workmen, who were equipped with jigs for drilling the frames and long before daylight the twenty-five workmen had fully equipped the 150 vehicles with fenders.



Organization convention of the Sheldon Axle & Spring Co., at the factory in Wilkes-Barre, Pa. The following were present: 1. Thomas Palmer, Gen'l Supt. Spring Mills; 2. F. L. Martin, Sales Mgr. Auto Axle Dept.; 3. H. L. Spohn, Class Journal Co., N. Y. City; 4. G. M. Wall, General Manager; 5. E. W. Acker, Detroit; 6. J. Fred Armstrong, Secretary; 7. J. A. Young, Trenton; 8. Chester A. Ide, Treasurer; 9. R. A. Schaaf, Engineering Dept.; 10. W. M. Jones, Cincinnati; 11. F. W. Kleist, Chicago; 12. David Landau, Consulting Engr. Spring Dept.; 13. O. A. Timberlake, Cincinnati; 14. E. J. Roth, Spring Dept.; 15. E. A. Shelly, Advertising Manager; 16. J. B. Kaler, Eng. Dept.; 17. A. M. Laycock, Chief Engineer Auto Axle Dept.; 18. L. E. Lyons, Detroit; 19. E. B. Flanigan, Eng. The Rostrum

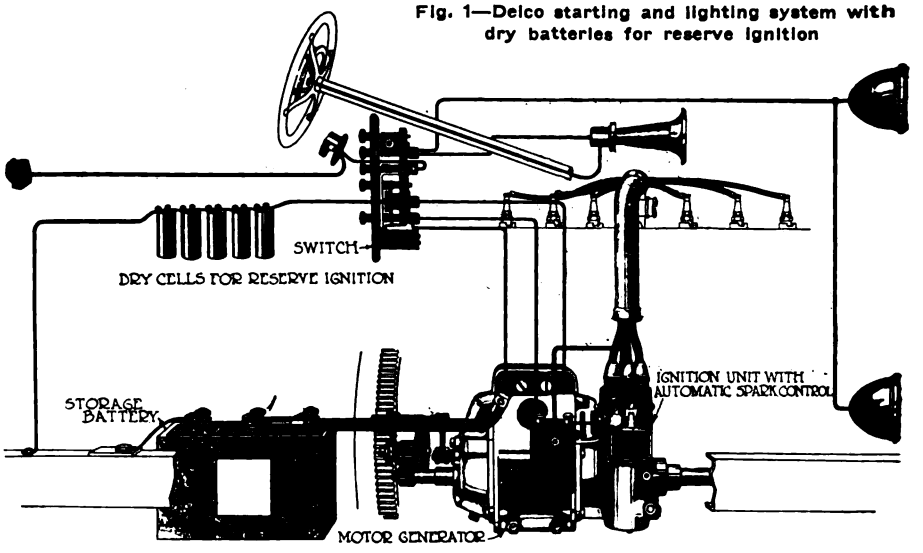

Fig. 1—Delco starting and lighting system with dry batteries for reserve ignition

Wizard D. C. Magneto Can Charge Battery

EDITOR THE AUTOMOBILE:—Several years ago the writer bought a Wizard magneto for furnishing current to run a model N Ford. I still have the magneto and have rigged it up on a 1912 Chalmers 30, and it furnishes current for a Klaxet horn. I have no way of telling the amount of current it makes, but from the way it blows the horn I thought possibly I could charge a 6-volt storage battery with it and in that way could equip my car with electric lights. This instrument was made by the Hercules Electric Co. of Indianapolis, and is their type FS-1.

As I understand it, it would require some means of controlling the output and a relay ammeter, etc. What information can you give me on this?

2—Would appreciate an estimate by you on the cost of everything necessary, exclusive of the battery and lamps.

Kings Mountain, N. C. W. S. D.

—Since the Wizard magneto is a direct current instrument, referring to type FS, it may be used for battery charging. This magneto can be used without an automatic cutout and when this is done it can be direct-connected to the motor by belting, the pulleys being so arranged that on minimum motor speed, the magneto speed will not be below 1600 r.p.m. At average motor speeds, the magneto speed should be around 2000 r.p.m. An installation of this kind will be the most simple because with it, the only switch which is required is a simple cutout placed between the magneto and the battery so that when the engine is stopped the circuit is broken and there will be no danger of the battery becoming discharged through the current flowing back through the magneto. Should this happen, it would be virtually a short circuit of the battery and would not only discharge same, but would also be likely to destroy it. When the magneto is connected to the battery in this way, direct-connected brushes or shunts should be used in the brush holders.

The Wizard magnetos are made for commercial power engines, and are designed especially for ignition with this class of work. For this reason, they require any transformation work to be done by mechanics of electrical knowledge and experience. It would therefore, be advisable in case you are not so equipped to turn the work over to an electrician.

2—The price would vary to such an amount with the manner of installation, that it would not be possible to give an estimate upon it which will be sure to be accurate.

In work of this kind it is rare that even the mechanic will fix his price in advance.

Dry Batteries Can Be Installed for Ignition

Editor THE AUTOMOBILE:—I have a D-45 1916 Buick which does not come equipped with dry batteries. Can they be installed? If so, how?

Would four batteries be sufficient for starting, in case the starting system should get out of order?

Round Lake, N. Y. W. N. G.

—Dry batteries are of practically no use on a car equipped like the Buick 1916, as the storage battery in the first place is sufficient for all requirements and in the second place, the batteries could not be substituted for the storage battery because the generator could not charge them and the chances are the generator would be damaged by working against the dry batteries. An ammeter is fitted on this car which shows immediately if the battery is not charging and gives plenty of warning should the storage battery be out of order. If you desire to fit an entirely separate dry battery ignition system working on the dual principle, it can be done by fitting the dry batteries to the car, then wiring to the distributer and coil, allowing the same high tension plug leads as are used for the present ignition system to carry the dry battery current. This would be solely an ignition system and would have nothing to do with the lighting or starting system which cannot be operated on dry batteries. As there is not sufficient energy contained in them.

Should the storage battery go wrong, which is quite unlikely, in a 1916 car for some time, you would have to start with the hand crank. In installing the dry batteries, five cells should be used, one terminal of the series connection being grounded and the other connected with the battery ignition switch. A diagram of the Delco system with dry cells for reserved ignition, is shown in Fig. 1. This is regularly placed on some cars.

Lifting Brush Protects Generator Circuit

Editor THE AUTOMOBILE:—In case it becomes necessary to take a battery off any of the starting and lighting systems of a car to be repaired, will the lifting of a brush protect the generator until the battery is put back into place?

2—Kindly explain by sketch the proper way to put new wristpins and bushings in a motor.

Pelham, N. Y. J. D.

—You do not state the make of generator to which you refer and hence it is impossible to give you other than a general answer with a few definite examples to cover the case you

mention. In general, it may be stated that the brushes of the generator should be removed if the battery is disconnected and the motor in use. Referring to the Gray & Davis system, for instance, if you were to remove the brushes a short circuit would be avoided and the possibility of burning out the dynamo would be removed.

Referring to the Delco ignition system, the lifting of one of the generator brushes will protect the generator during the operation of the car when the battery is removed. This method applies to all Delco generators prior to the 1916 production.

A constant potential system in general is not liable to injury if operated without the battery. A constant current system must be handled differently, as when operated without the battery, and no lamps lit, the generator endeavors to produce the constant current for which it is set and the only available place for this current to go is through the field circuit. The generator therefore reaches a sufficiently high voltage to send its rated current to the field circuit which is usually so high as to damage this field circuit unless individuality of design makes special provision for this and takes care that it does not occur.

On the Bijur system for example, the voltage regulated machine does not require any special attention to protect it and the lights may be operated directly from the generator if desired. On the constant current systems, however, produced by this concern, the brush must be lifted to protect the generator. On this instrument, the fields are excited from an auxiliary or regulating brush. On the Bijur Flexo generators, a fuse is provided in the field circuit which will automatically open the field circuit before damage occurs in case the gasoline engine is operated with the battery intentionally or accidentally disconnected. The most convenient way to protect the generator with this system when the battery is to be removed, is to remove the field fuse. The single unit systems do not have the field fuse and with them other means, such as lifting the auxiliary brush, should be used.

The automobile lighting generator of constant current type, with bucking series regulation, should not be run above the balance speed when disconnected from the battery. In case it is necessary to run the generator without the battery, the lamps and generator winding may be protected by removing either the positive or negative brush. This prevents the generation of a high voltage.

The Westinghouse lighting generators for automobile use using a Westinghouse automatic voltage regulator may be operated without the battery for a limited time without damage. This is possible because the voltage regulator prevents the voltage from being raised above a definite amount and protects the lamp and generator winding from being burned out.

2—Before this question could be answered properly by sketch or otherwise, it would be necessary to know the make of motor in order to determine the manner in which the piston pin is fitted. In some motors, the pin is held tightly at the upper end of the connecting-rod and oscillates in the piston bosses. In most motors, however, the wristpin is fixed in the piston bosses by means of a set screw which is passed through the boss and pin inside the piston and which must first be taken out before the wristpin can be driven out. This is a driving fit as a rule and can be hammered out by using a punch. The bushing for the wristpin generally fits in the upper end of the connecting-rod and is simply a bearing bushing which is installed in a manner depending upon the exact construction of the rod.

Tire Gages Proved to Be Inaccurate

Editor THE AUTOMOBILE:—A word of warning concerning the accuracy of tire gages might not be out of place.

Yesterday, while inflating with the free air supplied by that courteous gentleman, the garageman, three other drivers stopped and the subject of gages came up. Four gages were produced from as many pockets and all of different make. When tried on the same tire they were found to vary 15 lb. in their reading.

What of others in other pockets and their effect on tires? I submit the case to you.

Lansing, Mich. M. BECK.

—There is no question but that tire gages ought to be reasonably accurate and a variation of 15 lb. at an 80-lb. inflation is certainly more than reasonable. The question seems to be one which merits the attention of the gage manufacturer and also of the motoring public, who should insist on a comparison with a known accurate gage at the time of purchase. Naturally a dealer does not wish to sell inaccurate gages and if the customer so desires, he will be glad to compare the gage with one of known accuracy and if it is not within close limits, he should return same to the manufacturer. Gages should not vary to this extent ordinarily, because the concerns making them as a rule exercise quite rigid inspection methods to guard against this inaccuracy.

Transforming Phaeton to Fast Roadster

Editor THE AUTOMOBILE:—We have a 1913 Cadillac, phaeton body which we want to convert into a fast roadster. Can you give me any information regarding how we can fix up the engine? Also any other advice which you may have will be appreciated.

York, Pa. T. S. P.

—Generally, in arranging a motor for higher speeds, but two operations are performed by the ordinary motorist. One is to advance the magneto timing so that ignition is far enough advanced for the highest speed, and the other is to adjust the carbureter for high speeds. Sometimes the added expense of another camshaft is gone to, but not very often, as this entails the laying out of cams adapted to racing and the manufacture of an individual camshaft and the grinding of individual cams, which requires considerable money.

Another step which is often taken in adapting a motor to racing is to grind out the valve passage to allow for larger valves. On most motors this cannot be done and on the Cadillac the amount of metal which can be taken off at the valve seat would not justify the expense of the larger valve. If you will fit tight piston rings, advance the timing as far as you can carry it without having the motor knock and then adjust the carbureter so that a good powerful mixture is given at high speeds, you will probably have as good results as you desire. With the lighter roadster body, you would probably be able to stand a higher gearing than you have at present. As the country is hilly around York, however, it would be best not to go too far in this respect to get good performance. The same thing must be remembered in advancing the spark, in order that you will have good running when the engine is laboring in hill climbing.

Two Plugs Fire at Same Time

Editor THE AUTOMOBILE:—Having occasion a short time since to replace the crank, also the camshaft gear in a model B DeTamble D. opposed motor, after setting cams and magneto to fire at compression, was unable to get an explosion in the motor. The compression seemed good; also have new batteries. The plugs fired simultaneously. This car carries a Kurtz low tension magneto.

Three garagemen examined this and some said that it should not fire both plugs at once and others said it made no material difference. Can you say whether any cars fire two plugs in different cylinders at the same time?

3—I had an argument some time ago regarding the rota-

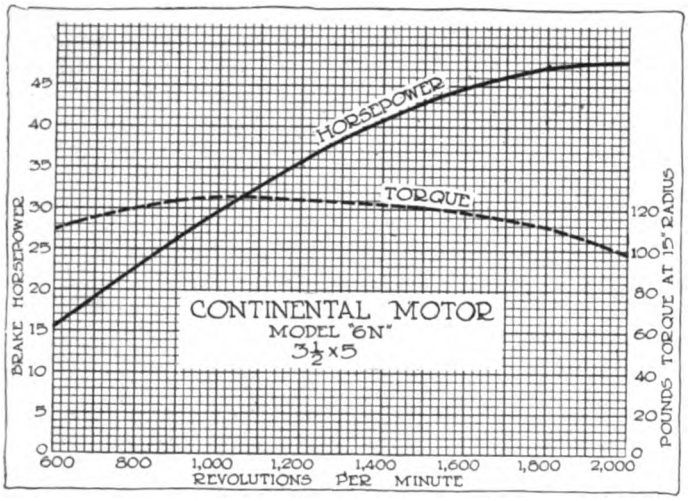

Fig. 2—Horsepower curve of 3½ by 5, six-cylinder Continental

tive speed of a camshaft. Can you mention a four-cycle motor wherein the rotative speed of the camshaft is different than at half of the crankshaft speed? The party claimed that it was different in different motors.

Hopkinton, Iowa. D. S.

—It is quite common practice with opposed motors for the magneto or ignition apparatus to be so arranged that a spark occurs in both cylinders at each revolution. This makes no difference as one cylinder will be on the exhaust stroke, with the other at compression. The reason you could not get an explosion was due to some other cause than that of ignition as long as you secured a good spark in each cylinder.

2—We have no record of any automobile employing a four-cycle motor in which the rotative speed of the camshaft is different than half crankshaft speed. Since the separate functions of a four-cycle motor occur at the same point during each alternate stroke. There are special design four-cycle motors with eccentric shafts geared one-to-one. Such a motor is described in this issue on pages 162 and 163.

Many Causes for Missing Motor

Editor THE AUTOMOBILE:—Would like an opinion on my motor trouble. My 1914 four-cylinder Studebaker misses when idling and when driving on high in different cylinders at less than 12 m.p.h. causing a very bad jerky motion apparently in the rear universal. Have had the valves ground recently and there is fairly even compression. The ignition seems to be all right and no change in the carbureter, which is a Schebler, seems to help it. There are apparently no air leaks and the car operates well when the motor has to pull; that is, when on a slight grade or on heavy roads.

Victor, N. Y. E. T. S.

—The motor missing may be due to loose connections in ignition wiring; broken conductors; breaker points burned out, dirty or improperly adjusted; valves not seating properly; dirt or water in gasoline; spark plug points improperly adjusted or not set deeply enough in the valve caps; weak battery; valve spring weak or broken; mixture too rich, or too lean; particles of carbon under the valves; defective spark plugs due to cracked porcelains or other causes; air leaks around the intake manifold, valve stem guides, valve caps, spark plugs or petcocks; valve lift improperly adjusted and many other minor causes. A good order of procedure would be to take the simplest points of the above list and go through those checking them off and then go into the more complicated causes.

The distributer contact should be carefully examined to see that good contact is being made and especially that all the contacts are clean. In case the valves are not seating properly, and the valves have been reground lately, examine the valve seat in the cylinder to see if it has become deeply pitted. It is sometimes necessary to take a light cut off the valve seat in the cylinder before proper seating can be secured.

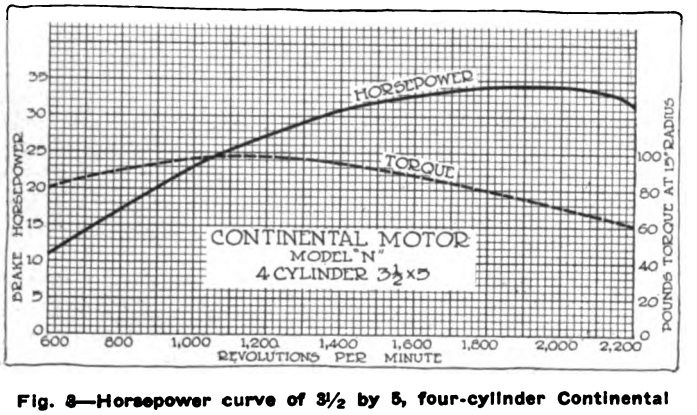

Fig. 3—Horsepower curve of 3½ by 5, four-cylinder Continental

Horsepower Curves of 3 1-2 by 5-Inch Motors

Editor THE AUTOMOBILE:—Have you a power curve of a typical 3½ by 5-in. motor such as in use in the representative makes of automobiles? What horsepower do these motors deliver at a speed of about 800 r.p.m.? I am figuring upon building a small gasoline tractor and any information you can give me about this size motor will be appreciated.

Mentone, Cal. J. L.

—Horsepower curve of typical 3½ by 5-in. motors such as are used in representative cars are shown in the accompanying illustrations. From these curves the horsepower and torque of this size motor at different revolutions per minute can be determined and as these curves give about as good an idea of the characteristics of this size motor as anything can do, further comment is unnecessary.

Connecting-Rod Bearing Probably Loose

Editor THE AUTOMOBILE:—I have a 1915 small Winton six and it developed a knock in the engine after running about 300 miles. This knock takes place when the car is running slowly on direct, or when the throttle is being opened and the car picking up. It seems to come about every two revolutions of the crankshaft. At the Winton shop they tell me that it is probably a side play of the connecting-rod between the piston bosses. I do not think that this looks probable as a connecting-rod with side play would also have side play on the crankshaft. They advised me to run the car a little and see if the knock did not disappear. I have run it 1000 miles and it is naturally still there. Can you give me any information on this?

Hopkinton, Mass. F. A. R.

—From the information you give the motor is evidently suffering from a connecting-rod knock. It is impossible to state whether the knock is due to side play or bearing looseness. Another possibility is that the motor has a piston slap which occurs at every explosion stroke. It sometimes happens that practically all the bearing of a piston is taken upon one ring. The result is that the piston oscillates about this ring which gives rise to a slap audible every two revolutions. Since you have had the car such a short time, you no doubt can make arrangements with the Boston branch of the Winton company to have this repaired.

Bad Oiling System Cause of Smoke

Editor THE AUTOMOBILE:—The other day when you found yourself in a dark blue fog of oil smoke, choking your breath and smarting your eyes, did you cuss motor cars in general? Well, you shouldn't. They do not all smoke—there is no real reason for any of them to be even in the slightest degree

objectionable on this score. You see many cars which are perfectly free from smoke from the exhaust. This *should* be the condition with all of them.

In some instances, it is true that the car user is responsible because he either carelessly or deliberately allows his motor to be over-supplied with oil. In the majority of cars which are smokers, however, the fault lies with the manufacturer. He has neglected to incorporate in his motor a competent oiling system.

The fact that many cars, or many different makes of cars do not look like soft coal burners turned loose on the street is ample and sufficient evidence that cars can be satisfactorily operated without the plume of odoriferous oily smoke.

The car user is as vitally interested in not smoking as his neighbors can be. The smoke offends them and destroys their peace of mind, but it costs the car owner dollars of his hard earned cash. For excessive smoking from a motor exhaust indicates the use of an excess of lubricating oil. The use of too much oil is not merely unnecessary, but positively vicious. It induces undue carbonization of valves, spark plugs and cylinder walls.

Carbon on valves means that they cannot properly do their work, and you have a motor of the hit and miss variety. Carbon on spark plugs means that they will ultimately short so cannot fire properly and must be removed and cleaned, which work, mark you, cures the trouble only temporarily.

A coating of carbon deposited upon the walls of that part of the cylinder used as a combustion chamber means a gradual increase of compression until finally your motor knocks easily when called upon to do a bit of real work. Such knocking is not pleasant or enjoyable, and if allowed to persist, causes undue bearing wear; such a condition means trouble of that variety which soon gets you into the mood where you feel like consigning your car and all that concerns it to that place where woolen underwear is not regarded as an absolute necessity.

Public demand has put the carbureter where it spends its time vaporizing gasoline, and does not try to set itself up as a perfume factory. Why not insist just as strongly that we get rid of that blue, greasy, foggy cloud of smoke from excess lubricating oil? It's easily done.

Detroit, Mich. W. A. BRUSH.

Formula for Calculating Piston Displacement

Editor THE AUTOMOBILE:—How do you calculate the displacement of a four-cylinder engine, a six-cylinder and an eight-cylinder engine in cubic inches? What I want to know is this: What is the displacement of an engine with four cylinders and a bore of 4.5-in. by 6.5-in. stroke? The formula I used was the following:

$\pi R^2 H$. $\pi = 3.1416$

$R^2 = R^2$ or radius squared

$H =$ Stroke of cylinder or 6.5 in.

The above formula is for one cylinder and for a four-cylinder engine would be four times the result of the above formula. The following is the result I obtained:

$\pi R^2 H$. $\pi = 3.1416$ $R^2 =$ Radius squared

$H =$ Stroke

4.5-in. bore by 6.5-in. stroke.

$R = \frac{1}{2}$ of 4.5-in. $= 2.25$ in., 2.25-in. squared $= 5.0625$ in.

5.0625 by $3.1416 = 16.00435 = \pi R^2$

16.00435 by stroke, or $6.5 = 104.028275 =$ Displacement of 1 cylinder; hence, for 4 cylinders $= 4$ by 104.02625, or 416.1131 cu. in.

I feel confident that the above formula is not correct and would thank you to put me right on this.

Detroit, Mich. E. M. DEW.

—Your method is absolutely correct but you have not carried out the work correctly. The fault is in the multiplication of 5.0625 by 3.1416. You have obtained as a result 16.00435 whereas, this should be 15.90435. Carrying the work to a conclusion will give you piston displacement of 413.5 which is correct for this size motor.

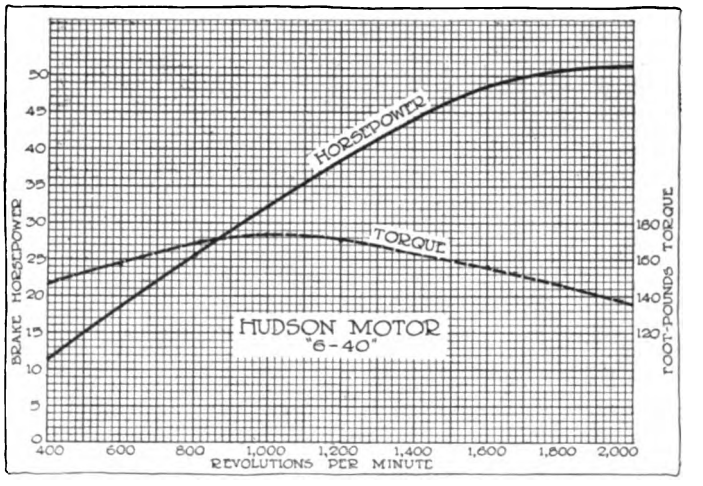

Fig. 4—Horsepower curve of 3½ by 5 Hudson six motor

Dimensions of Blitzen Benz and Jay Eye See

Editor THE AUTOMOBILE:—What is the size of the bore and stroke of the two racing cars, Blitzen Benz and Jay Eye See?

2—What compression have they?

3—What is the comparison of gears?

4—What are the sizes of the front and rear axles?

5—What is the horsepower?

St. Louis, Mo. R. L. H.

—The bore of the Blitzen Benz is 7.2835 and the stroke 7.8741 in. The Jay Eye See has a bore of 9.75 and a stroke of 8.625 in.

2—We have no records of any compression measurements on either of these two motors.

3—The gear ratios are changed frequently to meet track conditions.

4—The meaning of this question is not exactly clear as you do not state to which axle dimensions you refer. Since THE AUTOMOBILE has no detailed drawings of these parts at its disposal, a full set of dimensions cannot be furnished. The horsepowers of the two cars according to the S. A. E. rating would be 85 for the Blitzen Benz and 152 for the Jay Eye See.

Sign Your Inquiries

THE AUTOMOBILE *is in receipt of a number of inquiries signed by initials, the words Subscribers, Reader, Interested, etc. Since these letters give no clue to the sender they cannot be published in the Rostrum Columns. If you desire to use a nom-de-plume it is only necessary to add it to the signature, but the signature is necessary as an evidence of good faith.—Editor.*

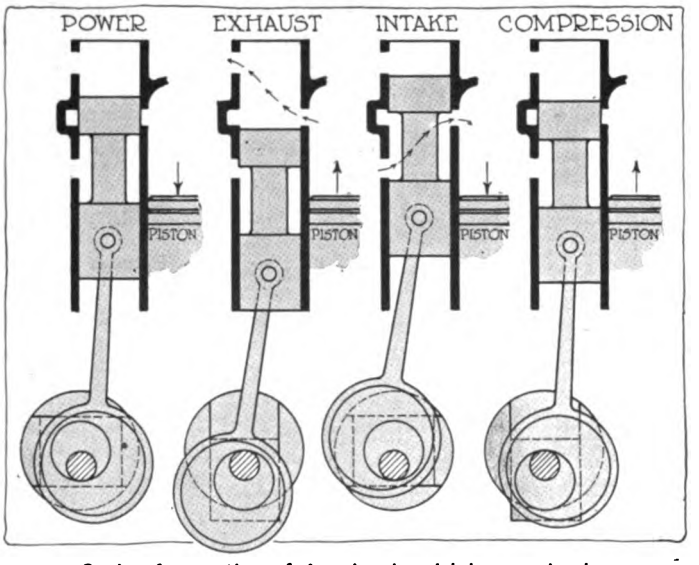
Appel Is Novel Valve-Driving Mechanism

A Positive and Silent System for Piston or Poppet Types



Cycle of operation of Appel valve-driving mechanism

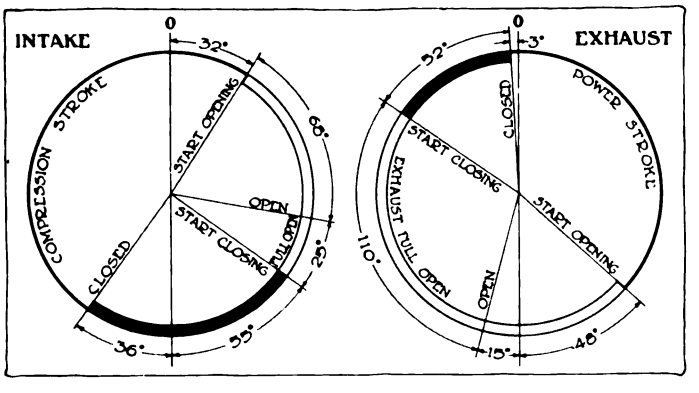


Diagram of Appel valve gear on intake and exhaust strokes

A VALVE-DRIVING mechanism for piston or poppet valves which is designed to be at the same time positive and silent, has been brought out by Daniel Appel, Cleveland, Ohio. This article is not being manufactured at the present time but has been brought out and is described as a novel development in valve gears.

The valve gear is so designed that it will operate a piston valve from a valve shaft which is driven at crankshaft speed by a set of one-to-one gears. On this shaft which is mounted as a countershaft on the model engine shown in the accompanying illustration, are arranged the operating eccentrics, one eccentric for each cylinder of the engine. The eccentrics are in pairs and are spaced at 180 deg., and between each pair of eccentrics and surrounding the valve shafts is a cylindrical rotary member which is arranged eccentrically with respect to the valve shaft and has a central sleeve-like portion journaled in a suitable bearing and provided at its ends with disk-like projections. The outer faces of these projections are provided with central transverse slots at right angles to each other and have parallel sides forming slideways for the slide blocks of the operating eccentric.

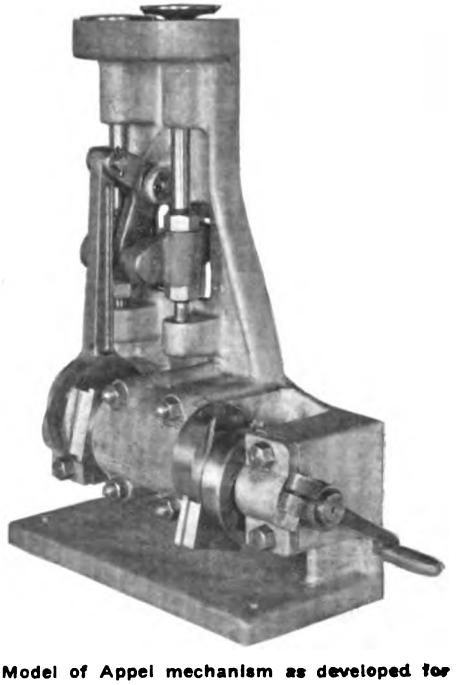
These slide blocks which form a part of the valve operating eccentric are bored to receive, with a running fit, the driving eccentrics of the valve shafts. Each block carries a valve operating eccentric which engages an eccentric strap and a transmitting rod, which operates the valve. This is shown in the constructional section view.

Rotary and Horizontal Movements

The drive is such that each of the slide blocks is given two movements, a rotary movement and a horizontal movement. Two cycles of reciprocating movement, and one cycle of rotary movement are completed during one complete cycle of engine operation. The resultant of the two movements, the rotary and reciprocating, is imparted to the valve operating eccentric, the center of which during one complete cycle of engine operation describes a closed approximately elliptical figure, having a re-entrant horizontal inward loop at one side about midway between the upper and lower ends of the figure. The center of the valve-operating eccentric while sweeping through the path of movement, has a velocity which varies from a high maximum to a low minimum. Assuming that the valve is in its lowest position with the center of the eccentric at the lower end of the figure or path of movement, and that the piston is at or near the middle of the exhaust stroke, the center of the transmitting eccentric is now at its maximum distance from the axis of the valve shaft and traveling upward along one side of the elliptical path of movement. This travel has the effect of giving the piston valve a very rapid stroke upward to its full open position so as to close the exhaust port and open the intake port. The intake port is full open when the valve reaches its uppermost position.

During the later part of the suction, and the early part of the compression stroke, the valve is given a quick but diminishing half-stroke downward, closing the inlet port, but at or near the end of the suction stroke, and during the major part of the compression stroke, the movement along the figure of travel is very slow, little movement being given to the valve.

When the center of the transmitting eccentric is near the end of the loop, firing takes place, and during the major part of the working stroke, the center of the eccentric is passing along the upper side of the loop, imparting practically no movement to the valve. During the latter part of the working stroke, and early part of the exhaust stroke, the valve is again given a quick and accelerating half-stroke downward to its lower position, again opening



Model of Appel mechanism as developed for poppet type motors

the exhaust port for gas passage.

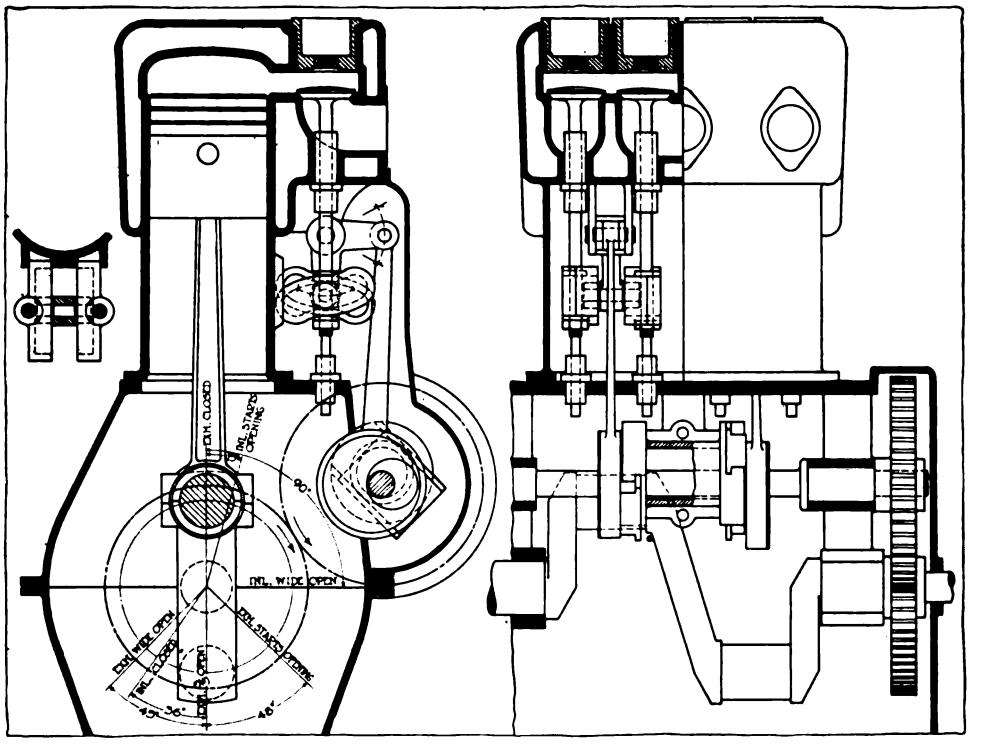
It will be seen that the movements thus given to the valve are such as are required to cause the poppet valve to function in the desired manner, for the inlet and exhaust ports are opened and closed at the proper time and the valve is held almost stationary in the mid-position with both ports closed during the major portion of both the compression and working strokes.

Both Movements

The two valve eccentrics used in this gear have both the movements which have been described. The exhaust valve passes through its 90 deg. before the intake and in a four-cylinder motor the other two cylinders, an opposite valve gear is provided for proper timing.

For Poppets

While this mechanism is intended primarily for piston or any other type of non-seating valves, it may also be used to operate poppet valves if connected with a device which will divide the valve gear movement so that the upward motion above the loop of the elliptical diagram will operate the intake valve and the downward motion below the loop the exhaust valve. The loop movement itself takes care of the active period of compression and expansion. Such a poppet-valve operating device is shown in the accompanying illustration. The movement of the poppet valve will be readily understood from the accompanying illustrations, the motion imparted to the bell-crank being identical with the valve motion above described.



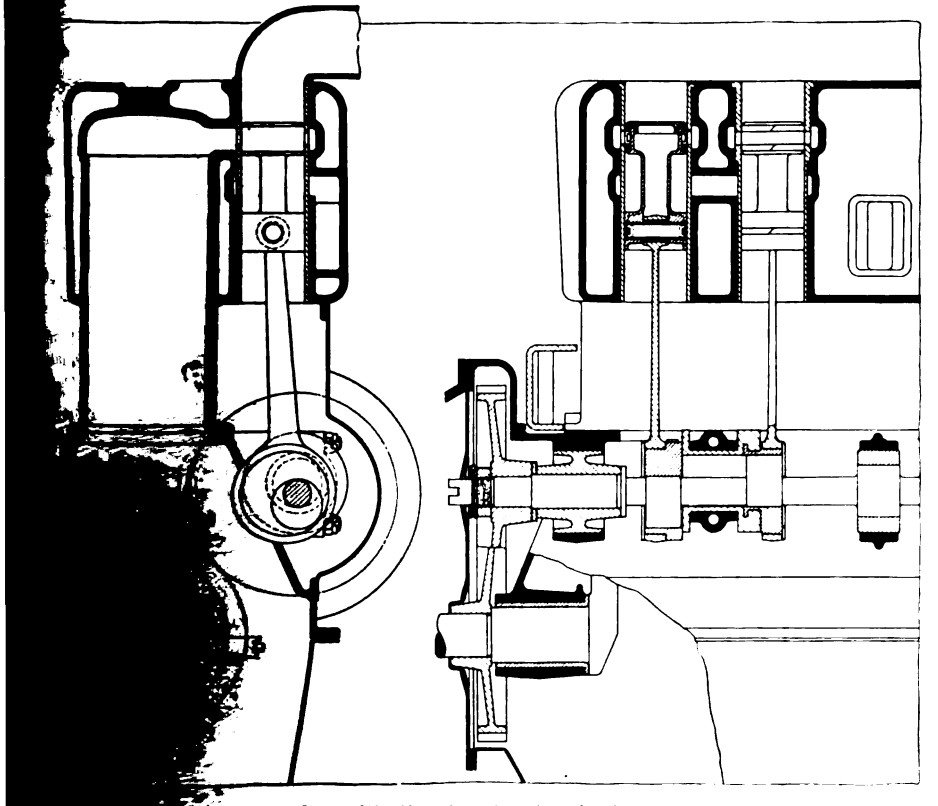
End and side sections of Appel valve-actuating mechanism with timing on a poppet-valve motor

The elliptical figure which is described by the valve linkage in its movement is shown in the sectional view of the poppet construction. The re-entrant loop will also be noted in this same figure. The functioning of the valve is so arranged that the quick opening and closing is secured without the noise which occurs from hammering of a follower on a flat-sided cam.

As will be noted in driving a piston valve the action is direct, the eccentric rod being pivoted directly to the piston valve and transmitting the motion imparted by the eccentric and slide-blocks without any intermediate linkage. For this reason, the full advantage of the motion would be gained in a piston or sleeve valve, although the action is not at all undesirable for poppet valve motors due to the possibility of securing quick opening and closing.

One of the advantages claimed for this type of drive is that at no part of the cycle is there any impact between different members of the operating mechanism, all contacts being of a sliding nature and hence without shock. No sacrifices in timing need therefore be made considering the intervals between the time that the valves start to open and are fully opened. Referring to the diagram given on the opposite page it will be noted that the intake starts opening at 32 deg. and is fully opened at 100, the travel being through 68 deg. while opening. The valve remains full open during a period of 25 deg.

With the exhaust the opening period is 63 deg. and the valve remains fully open during 110 deg. and closing during 52 deg. This timing can of course be varied.

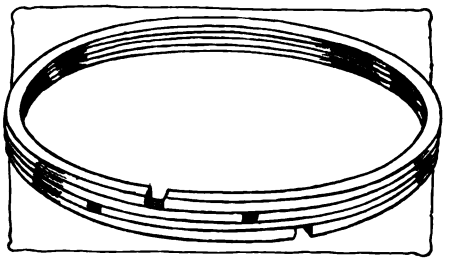


motor with the Appel valve-driving mechanism. Note timing

ACCESSORIES

Perfection Piston Rings

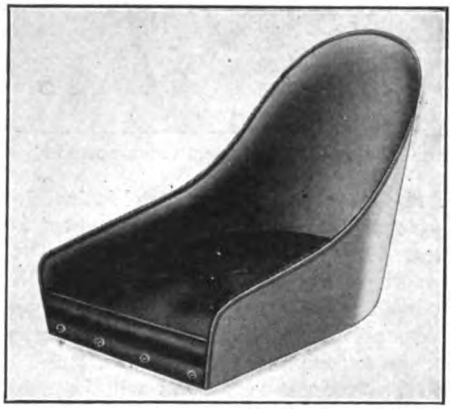
PERFECTION is the title of a piston ring of the multi-part, anti-leak variety. It is in the form of four small rings fitting into a single groove, the rings being made of special soft steel, heat treated, so that they soon lap themselves into the cylinder, and because of the softness of the metal, as compared with the cylinder walls, there is said to be no possibility of scoring the latter. This type of piston equipment is claimed to prevent leakage of mixture and oil past the piston. An additional advantage is that in installing the ring it is not necessary to spring it over the piston head. The separate rings are made in sections less than ⅛ in. wide and afford sufficient space to retain oil between the sections and also between the unit ring and the groove.—Automobile Construction & Engineering Co., Philadelphia, Pa.



Perfection piston ring which is made as four small rings fitting into a single groove, these rings being made of special soft steel so that they cannot score the cylinder walls

Belfast Racing Seats

To meet the demand for racing type seats which can be installed on any body by simply fastening them to the body frame with wood screws, the Belfast seats have been produced. The back is of 22-gage metal, well ironed to the wood-framed bottom and upholstery is in red or black imitation leather, well padded. The bottom cushion is removable and the back of the seats is painted battleship gray. The seats sell for $8 each or $15 per pair.—Belfast Mfg. Co., Station K, Cincinnati, Ohio.



One of the Belfast racing seats designed for cars remodeled into raceabout or speedster types. They are light but strong in construction and the cushion is removable

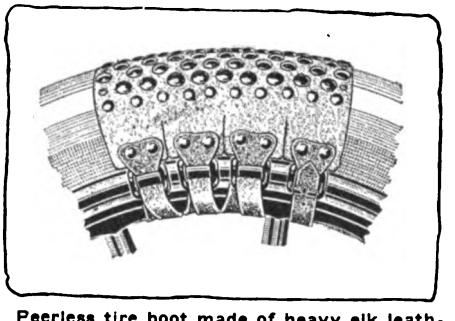
Schrader's Valve Box

As an improvement in the packing of its valve insides, the Schrader organization has brought out a small tin box large enough to carry five insides. This container is damp proof and dust proof, and is grooved so that each inside is kept separate from the rest, insuring their reaching the consumer in perfect condition. The box will appeal especially to dealers who have had to handle the valve insides in bulk up to this time. The box sells for 20 cents.—A. Schrader's Son, New York City.

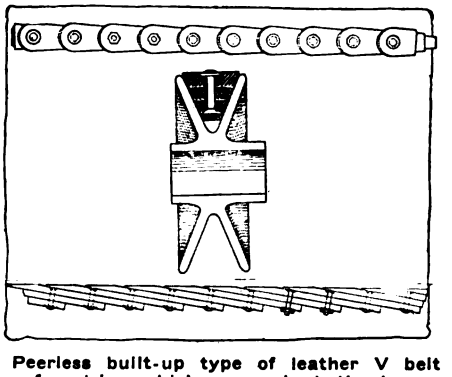
Peerless V-Belts and Boots

A strong and flexible V-belt for fan service, which hugs the pulley well. Both chrome and oak-tanned leathers are used. Prices, chrome, ½-in., 60 cents per foot; ⅝, 66 cents; ¾, 72 cents. Oak, 42, 48 and 54 cents per foot.

Elk leather is being used on a number of the Peerless products, one of the products being a heavy boot, fitted with straps so that it can be attached to any tire. The leather is tanned in such a way as to make it non-stretching and waterproof, the maker states; and the tread is reinforced with a studding of flat-headed rivets that will stand about 1000 miles service. The attaching straps are of 1-in. width, of heavy stock. A lighter strap boot is also made, as well as light and heavy boots of the hook type. Price, 3-in., $1.95; 3½-in., $2.25; 4-in., $2.50; 4½-in., $2.75; 5-in., $3.—Leather Products Co., Denver, Col.



Peerless tire boot made of heavy elk leather and studded with steel to endure 1,000 miles of service. The attaching straps are 1 in wide and of heavy stock



Peerless built-up type of leather V belt for fan drive which comes in both chrome and oak-tanned stock. It hugs the pulley

Bumper and Fender

A combination bumper and fender is shown in this sketch, the idea being that the usual position will be horizontal, but that the driver has a hand control that allows the device to drop should an accident threaten. Since the bumper fits on the spring bolts it is easy to attach, and no holes have to be drilled. It can be adjusted to suit any sort of car, though special patterns are made for Fords and trucks. Three classes of finish are made, all black, part nickel and all nickel, the prices being $22.50, $25 and $27.50, respectively.—Auto Safety Fender Co., Pittsburgh, Pa.

Raffia Tonneau Mat

A green tonneau mat of raffia grass which is very soft but tough and which is claimed to be more durable than other varieties of tonneau floor coverings has been put on the market recently. It is made in all sizes and for all makes of car, the price varying from $5 to $7, according to the size.—Pastre's Auto Garage, Brooklyn, N. Y.

Orolo Carbon Remover

A new carbon remover and engine cleaner is called Orolo. This is a liquid, which, when heated is said to be immediately converted into gases which completely destroy the asphaltum contained in carbon, leaving only a black powder or soot which is blown from the exhaust when the motor is started. It contains no acid, is not injurious to human flesh and cannot possibly injure metal of any kind. This is demonstrated by the fact that it is put up in thin, sheet-iron tinned cans. The use of Orolo every 30 days or 6 weeks will keep a motor free from carbon and add at least 300 per cent to the life and efficiency of the motor, it is claimed. It sells for $2.50 a can.—Orolo Mfg. Co., Louisville, Ky.

Frey Shield and Goggles

Rain or snow on a windshield prevent the driver from getting a clear vision of the road ahead and render driving dangerous. With this in mind the Frey organization is marketing a shield designed to prevent this difficulty, a visor-like device made of pyralin, a transparent ma-

terial like celluloid, being attached to the windshield by five vacuum cups, which the makers guarantee to hold so firmly that the shield cannot blow off. The shield keeps the rain off the glass, a rubber sealing strip fitting tightly against the glass so that there is no crack where it can leak through. When not in use the shield can be rolled up and stowed away. It sells for $1.50.

A line of two-color goggles is also put out by the Frey concern under the name of Dimmer goggles. These are also made of pyralin which is unlike celluloid in that it is not easily affected by heat and does not give off a disagreeable odor in an excessively warm atmosphere. The goggles are divided, as illustrated, the lower part being of an amber shade while the upper is green or orange. By raising or lowering the head the line of vision may be made to pass through either the upper or the lower portion of the lens. Different color combinations are offered. The goggles are listed at 75 cents.

Another Frey accessory is a paste varnish called Protexacar which is claimed to effectually protect the finish of a car from the deleterious action of water, heat and dirt. When the paste is applied to the surface of the body and chassis it is said to form a hard coating impervious to the elements. It is necessary to renew the coating only once every five or six weeks, as washing of the car does not affect it. Protexacar is applied with a soft cloth and is said to dry instantly. It is put up in ½-lb. cans which are sold for $1 each.—Frey Mfg. Co., Chicago, Ill.

Stull Ford Starter

This starter for Ford cars adds but 18 lb. to the weight of the machine, can be installed without machine work or drilling and does not appreciably interfere with the accessibility of the side of the motor on which it is placed.

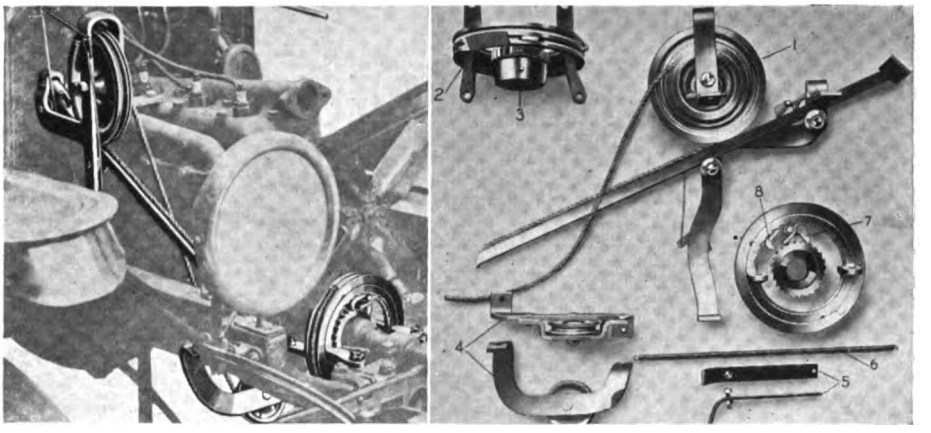
The starter consists of a pedal, projecting through the lower part of the dash just to the right of the coil box, on the end of a plunger rod; a pulley operated by a steel cable attached to the plunger; a smaller pulley integral with the first and carrying a second steel cable which extends over a guide pulley to the front of the motor; and a ratchet mechanism on the crankshaft which imparts motion when the pedal is pushed and which automatically disconnects in case of a backfire.

Referring to the illustration, it will be noted that the plunger rod has attached to its lower end one end of the steel cable that runs over the large pulley 1; the other end is fast to the pulley. The rod is guided by steel rolls running on studs on the bracket. One end of the second steel cable is attached to the smaller of the two integral pulleys, the purpose being to increase the leverage or, in other words, to lower the gear. The other end of this cable is fast to the crankshaft pulley 2. The pulley 4, bracketed at the front of the frame, serves to give the cable a right-angled change of direction. The crankshaft pulley has attached to it a long coiled spring 6, the other end of which is attached to the car frame. This brings the moving parts back to first position, ready for a starting stroke, when the pedal is released.

The final pulley is really a steel ring running on sixty-eight steel balls on a stationary ring which is held against rotation by arms bolted to the crankcase bolts. Attached to the crankshaft and carrying with it a special fan-belt pulley 3, which is part of the outfit, is a ratchet wheel driven by the main pawl 7, on the outer pulley ring. The stationary ring carries the backfiring pawl 8, which automatically releases if the motor kicks back.

As the tendency of the spring is to push the whole system, including the pedal, into starting position, the pedal is held down normally by a little latch projecting through it. Placing the foot on the pedal automatically releases the catch and permits the pedal to rise. A downward push carries two pistons over compression. When the motor is warm this is sufficient, as a rule, to start; but when cold, priming is required for a quick start. The starter is equipped with its own connection for priming the motor from the dash, replacing the original front primer.

The maker states that any first-class mechanic can install the starter in two or three hours. The cowl-dash Fords can be equipped, as well as the straight dash models. Full instructions and blueprint are furnished with each outfit, the whole being packed in a wood box. The price is $15.—Stull Starter Co., Sunbury, Pa. Nelson T. Gutelius, New York City, distributor to the trade.



Left—Stull mechanical starter for Ford cars, illustrating the method of mounting the starter on a Ford motor. Right—Parts of the device, showing simplicity of construction. The system is said to add but 18 lb. to the weight of the car and to be installed without interfering with the accessibility of the motor to any appreciable extent. The starter is actuated by a pedal which connects through steel cables to a ratchet mechanism at the front

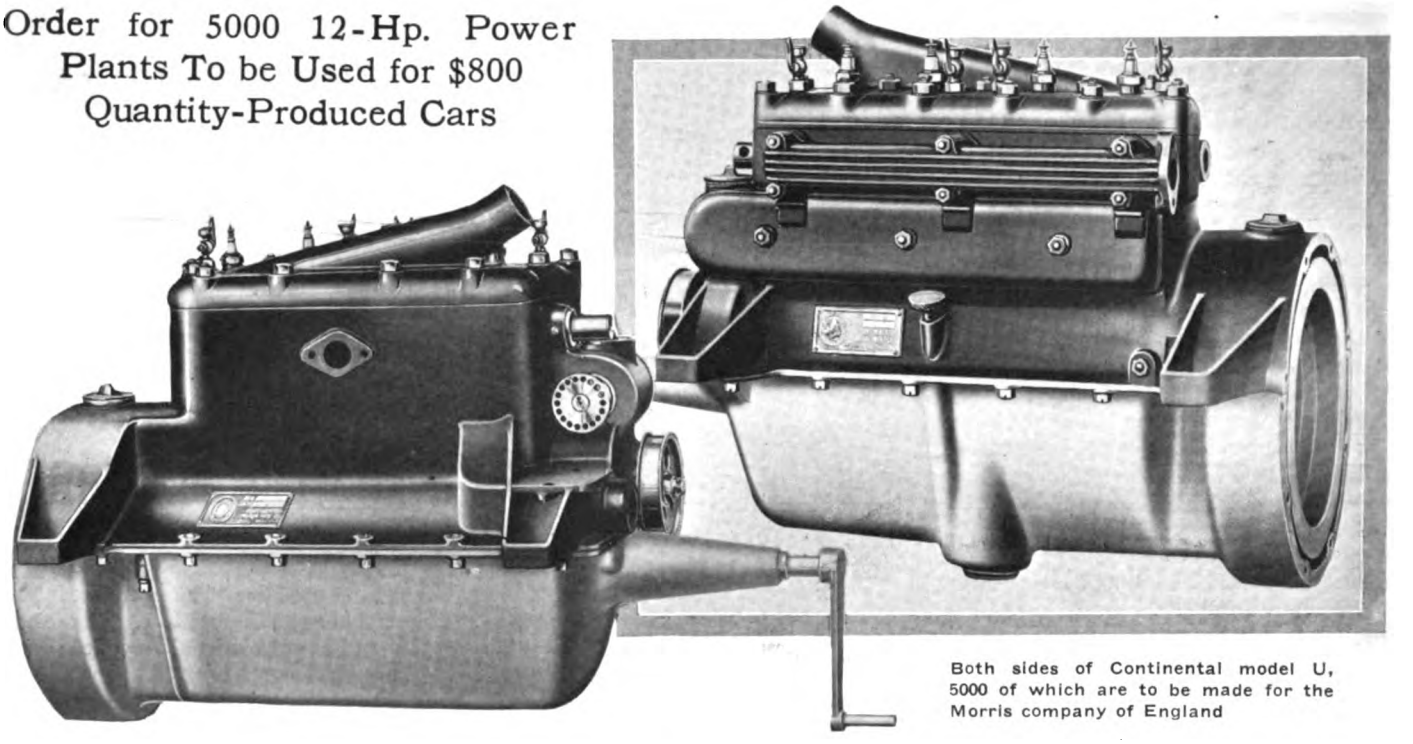
Continental Motor for British Car

Order for 5000 12-Hp. Power Plants To be Used for $800 Quantity-Produced Cars



Both sides of Continental model U, 5000 of which are to be made for the Morris company of England

DETROIT, MICH., July 20.—What probably marks the entrance of a car manufactured on the American assembly scheme into the English field, is brought out by the announcement of the Continental Motors Mfg. Co., which is to produce a light weight high-speed type of motor of small piston displacement in quantities for the Morris Motor Car Co., Oxford, England. This motor has been primarily designed to meet the European demand for minimum horsepower compensated for by high motor speeds, but may also be found suitable for use by American automobile manufacturers.

The motor is a four-cylinder L-head cast in a block with the cylinders and top half of the crankcase cast integrally. The cylinder head is detachable, permitting access to the valves, pistons and combustion chambers, and the lower structure of the motor is accessible by dropping the bottom half of the crankcase. Four supporting arms are cast upon the crankcase and the rear end is so arranged that a unit power plant could be accommodated, the size of the plant being such as to accommodate several of the standard gearset and clutch units. The bore and stroke are 70 by 102 millimeters or 2¾ by 4 in. This gives a piston displacement of 95 cu. in. and an S. A. E. rating of 12.08 hp. It is stated that the actual brake horsepower developed at 2000 r.p.m. is 18.

Three-Bearing Shafts

Both the crank and camshafts are supported on three bearings, the crankshaft being 1½ in. in diameter. The steels used in these parts is of special composition drop-forged and heat-treated, giving a tensile strength of 90,000 lb. per square inch. Lubrication is by force feed and splash and cooling by thermo-syphon. The carbureter is the side-outlet design bolting directly to a flange on the cylinder casting with the intake passage entirely within the cylinder blocks. The fan is four-bladed and is of steel, being driven from its pulley on the front end of the camshaft. The weight of the motor assembly, exclusive of accessories, is said to be approximately 270 lb.

According to the present understanding, the Morris Motor Car Co. has contracted for 5000 of these motors which will be known as model U. These cars which are to be made during the coming season will be the first assembled British automobile to be produced in any quantity. The car is to be rated at 12 hp. and will sell for about $800 on the other side, although it is stated that a car of similar type could probably be produced and sold in this country for considerably less.

Meeting Arctic Conditions—Buick on Runners

The big sporting event of the year in Nome, Alaska, is the annual sweepstakes race between teams of malamutes and Siberian wolves. The accompanying illustration shows how Jack McQuire took in the finish and the start of the race at Nome, having converted a four-cylinder Buick in that far northern gold camp into an automobile sled, which enabled him to keep up with the contestants throughout the race

Small Fours Returning

THAT fresh attention is about to be given to the fairly small four-cylinder motor is now certain, and there is little doubt but that we shall see shortly, not one but several, small fours emerging from factories where nothing but the very highest class of work is done. They will be made for quality just as carefully as the largest six or twelve and their price will not be very low, in fact, the cars will be built first and the price made to suit rather than the other way about.

Also it seems more than probable that at least one of the big producers of medium-priced cars will introduce a high-speed four of good quality at about the price now demanded for the average light six, between $1,000 and $1,250.

In making this type of car whether the price is $1,000 or $3,000 light weight will be the greatest consideration and the seating capacity will certainly not exceed five passengers. It is hinted that one car may even be produced at a quite high price with four passengers as the maximum load.

This, of course, is in accord with European practice, since the light, high-speed, four-cylinder motor is only really satisfactory for a reasonable load. With such a load, however, it makes the cheapest possible car to run, for, gasoline and oil efficiencies are very high and tire life in proportion to the light weight. Naturally such a car as a high-priced four will appeal to a certain class of user only, for the man to whom big seating capacity is everything will not find it suitable, but there must be thousands of people to whom a small car of high quality and great durability, good speed ability and the comfort that only costly bodywork can give, will appeal more strongly than larger and less well made chassis.

If things work out as the experiments in progress now indicate it is safe to predict there will be a mild boom in fours once more, the probable ultimate effect being to add a type of car to the American industry's output which will take a permanent place in America, and also be the finest export proposition possible.

Truck Safety

MOTOR truck owners are more than ever convinced that it is good business on their part to actively take up the question of greater safety in connection with the operation of trucks in our larger cities. Efforts on the part of truck owners to improve the safety precautions are not confined to such centers as New York, Chicago and Boston, but have been actively taken up in a score or more of the smaller cities. Experiments made in a Kentucky city last year, with folding rear steps on ice delivery wagons, showed a perceptible reduction in the number of accidents due to children riding on the steps. In New York certain mercantile associations are looking for safety devices and are willing to offer premiums in a few cases for feasible devices. The Fifth Avenue Coach Co. in voluntarily fitting fenders to guard the rear wheels of its coaches is a specific example of how strongly this safety movement has taken hold on our big motor vehicle operators. The coach company is convinced that it is a business investment.

This suggests how imperative it is for our police and traffic departments to better regulate the crossing of streets by pedestrians. It is accepted that pedestrians and vehicles have equal rights on our streets, each having at all times due regard for the safety of others, but it does seem unreasonable to hem the operation of motor vehicles around with restrictions and leave pedestrians free to wander at will to their own destruction.

Weekly Business Reports

THIS week THE AUTOMOBILE publishes the first of its weekly business reports on the condition of the industry not only in manufacturing centers but in many of the largest distributing centers. Our metal markets are reported each week through their respective channels, periodically our banks make public statements, weekly reports on building operations throughout the country are made use of, and it is opportune that the automobile industry is deserving of weekly reports that are carried into every State. The magnitude of the industry is yet not seriously considered by many of our 100,000,000. The time has arrived when the automobile light should not be hidden under a bushel.

300,000 Fords Built in Year

World's Production Record Established—Owners to Receive $15,000,000 in Rebates

DETROIT, MICH., July 16—To-day car No. 300,000 was turned out at Henry Ford's plant. It was not only a record for the Ford Motor Co., but it was the world's record, as no other automobile manufacturer has ever approached such a tremendous output, even in two years or three, not to speak of less than one.

Thus the prophecy that 300,000 Ford cars would be made in the 1915 fiscal year of the company has been realized, and when that fiscal year ends, July 31, the total output will be brought up to about 315,000 cars.

This total is by no means the most the company could make. At the present time the plant is not running to its full capacity, as is always the case when nearing the end of the fiscal year and when about to take its annual inventory.

Incidentally it might be mentioned that the history-making car No. 300,000 bears motor No. 850,938, which would seem to mean that up to that time just that many Ford motors, or Ford cars, have been made.

—

Hunt Packard Chief Engineer

DETROIT, MICH., July 15—O. E. Hunt has been appointed chief engineer of the Packard Motor Car Co. by J. G. Vincent, vice-president of engineering. Mr. Hunt was Mr. Vincent's assistant for several years. There are now over 200 members on the engineering staff of the Packard company, which concern expends from $400,000 to $500,000 annually on development work, it is said.

Graduating at the University of Michigan in 1907, Mr. Hunt followed another profession for two years and then determined to apply himself to the automobile industry. He obtained employment in the Packard drafting room and soon became chief draftsman of the truck department, following which he took over the body department and then became assistant to D. S. Waldon when the latter was vice-president. From this post he acquired the position of assistant chief engineer under J. G. Vincent in which capacity he was acting until his present appointment.

—

Hannibal Truck at $500

HANNIBAL, MO., July 17—N. L. LaBlond, manager of the Hannibal Wagon Co., announced to-day that his company soon would begin the manufacture of a light commercial motor truck the price of which will be in the neighborhood of $500. The new vehicle will be known as the Hannibal truck.

According to Mr. LaBlond, the company has an initial order of 100 trucks, which are to be delivered as fast as they can be put out of the factory. A large extension to the wagon plant at South Tenth and Collier Streets is now being planned.

An engine especially designed for the Hannibal truck is now being manufactured in Detroit, Mr. LaBlond said. The engine will be of 25 hp. and the hauling capacity of the truck will be 1200 lb.

—

Jackson Prices Lower—Two Eights and a Four

DETROIT, MICH., July 19—Three new models, two of them equipped with eight-cylinder engines and the third with a four-cylinder motor, are the 1916 line of the Jackson Automobile Co., Jackson, Mich., these replacing the four- and six-cylinder 1915 models. The eights are in two sizes, the smaller, designated as model 348, having 112-in. wheelbase and selling at $1,195, with 2⅞ by 4¾ in. motor. The larger eight, model 68, is a $1,685 car with seven-passenger body on a 124-in. wheelbase chassis. Its motor is 3½ by 4½. In the four-cylinder model 34 chassis, the motor is 3½ by 5 and the wheelbase is 112. This car is to sell at $985.

These prices are all big reductions for Jackson, as last season's four sold for $1,375 and the six was $1,650.

The motors used are all Northways, and the two eights follow the same general design throughout. The two-cylinder blocks are at 90 deg., and the crankcase is split vertically into two halves, one being integral with each set of cylinders. The four is the standard Northway design with detachable head. The larger eight has a horsepower of 70; that of the smaller eight shows from 45 to 50, and the four develops 38. These powers are all at 2700 r.p.m., and it is evident that the engines are really all of the high-speed type.

Models 34 and 348 have 32 by 4-in. tires, and the 68 is fitted with 34 by 4½.

—

Carter Capital Now $600,000

PONTIAC, MICH., July 17—Notice concerning the decrease of the capital stock of the Cartercar Co. from $650,000 to $600,000 was filed with the county clerk, the document being signed by President Thomas Neal, Secretary T. S. Merrill and Directors Thomas Neal, C. W. Nash, M. J. Murphy and Emory W. Clark. The decision to reduce the capital stock was taken at a recent meeting of the stockholders. It is stated that the amount subscribed after the decision to reduce the capital stock had been taken was $557,720.

Overland's June Shipment 9010

An Increase of 163 Per Cent Over June, 1914—11,400 Men Working at Plant

TOLEDO, OHIO, July 15—The Willys-Overland Co. shipped 9010 cars during the month of June, an increase of 163 per cent over the shipments of June, 1914, when 3298 cars left the Toledo factory. In the first six months of the calendar year the company has shipped almost as many cars as it did during the entire twelve months of 1914, or practically doubled last year's output.

The previous mark was in the month of March, when 7005 cars were shipped. The record shipment for June exceeds these figures by about 30 per cent.

Export shipments, not including Canada, this country having more cars shipped and sold there, so far this year, than during the whole of 1914, were found at the close of June to be fully 70 per cent of the entire export shipments of 1914.

A record was also established in unfilled orders which amounted to 20,000. The present production is about 400 cars a day. Mr. Willys plans to increase this production to 600 cars a day before the expiration of the present season.

The employees number 11,400 and the plant is going at full capacity. Many of the departments are working on a continuous 24-hour schedule, which keeps a night shift of 1500 men busy.

—

Prest-O-Lite to Make Steel Parts

INDIANAPOLIS, IND., July 19—The Prest-O-Lite Co. is preparing to manufacture car parts made out of cold-drawn steel, such as axle housings, cylindrical gasoline tanks, brake drums, etc. At the present time the company has at its local plant one of the largest batteries of presses for drawing steel. The facilities have recently been increased by the addition of some new presses, including one of 800 tons capacity, and the concern is ready to handle work of this kind from blueprints.

—

Prest-O-Lite Sues Sun-Lite

LOUISVILLE, KY., July 16—The Prest-O-Lite Co. has filed an injunction suit and a demand for an accounting of profits in the United States District Court here against the Sun-Lite Gas Co. a corporation of Louisville, Thomas F. Hackett, its president; C. A. Tucker, vice-president; J. J. Moran, manager and Margaret Moran, defendants. In the suit it is claimed the Louisville firm has been refilling Prest-O-Lite tanks.

Retail Car Sales Brisk—Marked Gain Over 1914—Reports from All Sections

New York Sales Heavier in All Classes of Cars—Boston Dealers Exhaust Allotments—Detroit and Indianapolis Factories Rushed—Parts and Accessory Concerns Busy

NEW YORK CITY, July 21—Automobile business throughout the country has during the past week averaged much above that of the corresponding week a year ago. With many of the popular-priced cars listing at under $1000, business has increased 100 per cent as compared with 1914, and in a few cases the demand of buyers has been three times that of a year ago. In the Central West there is a pronounced return of confidence in the financial situation, which is aided by improved road conditions, both potent factors in the purchase of cars.

Boston dealers all report increased trade as compared with the corresponding period a year ago, there not being a single exception. Some are being held up by lack of cars, but in general car shipments are in advance of last year and the business is waiting, dealers in four or five of the largest car producers being nearly two weeks behind in orders.

New York Trade

The New York metropolitan area embracing a population of over 8,000,000 is enjoying vastly improved selling conditions. Overland reports business 300 per cent ahead of a year ago, Ford is 135 per cent ahead, Buick places the increase at 300 per cent and Studebaker at 100 per cent. In the high-priced field Packard reports vastly increased business, Pierce-Arrow is on a par with a year ago and Locomobile has made gains. In the medium-priced field, namely $1000 to $2000, sales have been generally heavier than a year ago. Values in second-hand cars have gone up very materially largely due to the increased demand for new cars.

The Chicago field as representing the Central West has been very active. A few examples will serve to show how the demand has increased; Hupmobile business is double that of a year ago; Chalmers 25 per cent increase; Buick behind in 1916 deliveries; Hudson much in advance of last year.

Boston Market

A detail review of the Boston market as typical of New England shows very general increase in business. In the medium-priced class the well-known cars like Jeffery, Chalmers, Hudson, Velie, Reo, Cadillac, Chandler, etc., have left 1915 behind them and they are on the 1916 path. In the higher priced class the Marmon, Locomobile, Packard and Pierce did better than preceding weeks. The weather was good for sales because it was warm and tended to get people outdoors. The demand for second-hand cars exceeds the supply. And last week a number of people wandered into places looking for used cars and ordered new ones when assured of a speedy delivery.

In the electric car field some of the dealers reported the past week no better or no worse than before. Boston is not a first class electric pleasure car city. But some of the electric truck men said they did better than a year ago. And the hot weather seemed to have started business men into buying trucks, gasoline vehicles, for they made more sales. As a general summary if the dealers all had machines on the floor ready to pass out for cash the sales would have soared away up, for the preceding weeks had been rainy and cold so that motoring was not a pleasure, particularly over the week ends. And what is true of Boston is reflected in other parts of New England.

Indianapolis Makers

Conditions among the automobile manufacturers in Indianapolis are all much superior to those of last year in July.

The National states that its contracts for material and selling contracts provide for the building of 2500 cars for the year ending July 1. Officials state that this number will undoubtedly have to be increased to meet additional demands. The Empire has been kept in full swing throughout the entire spring and summer. The new plant will allow a great increase in production. Business for the season exceeds all other years by 50 per cent. This has been of four-cylinder models. Work has now started on six.

The Pathfinder company is basing its yearly production on 3500 basis of sixes and twelves. From present contracts its models will be very evenly divided. Officials say the sales outlook is wonderful. Hundreds of inquiries were received last week from distributors and contracts received to-day from ten large distributing centers.

Marmon is building cars at 700 capacity, and says that the demand is greater than before with the high spots in New York and Chicago. Say Pacific coast business is also excellent.

Stutz doing capacity business. Building cars in series of 500; expect to build from 1000 to 1500. At present rate of demand they will go over these figures.

Retail and wholesale conditions in St. Louis and territory are the best they have been for twelve years. This territory includes Missouri and parts of Kentucky, Arkansas, Tennessee and Illinois. Overland volume of business was four times that of a year ago during the same week. The distributor is 600 cars behind in delivery. Ford business is 150 to 200 per cent over last year. All dealers are booking heavily 1916 business and lack of cars is the greatest trouble.

Northwest Wants Cars

The practically universal note among Northwestern distributors in Minneapolis is inability to get cars. This condition was not improved last week, and yet orders began to come in for 1916 model deliveries. The new season begins here Aug. 1, but one firm had already sent out 100 new models. In this territory the slack season is July and August, and, somewhat delayed, it is undeniable that this drop is being felt just now. One reason is the unsettlement because of new announcements of models and prices. Another is that at this time the farmer, who is a heavy buyer of motor cars, is turning his attention entirely to his crops.

With this slight turn in the demand for cars one of the most remarkable seasons in Twin City headquarters of automobile concerns was interrupted. The only hindrance to business, apparently, was inability to get cars for the dealers.

In the truck line normal conditions seem to have reversed. Spring business ending at this time has been under expectation and the outlook to-day for fall business is unexcelled, if crops are up to the prospect.

Detroit at Pressure

For the week ending July 17 Detroit had no cessation in the demands of dealers for cars on the one hand, and in the efforts of the manufacturers of cars and parts to keep pace with required production, on the other.

July is proving a busy month. Last week six concerns besides Ford turned out well over 100 cars a day, two of these doing considerably better than twice that number.

Selling conditions throughout the country seem to have been in the best of shape last week. The farmers have been buying many cars, and the feeling seems to be that as the year's crops are among the best we have ever had, there is really more money in circulation in the farming districts than in many years.

With the foreign situation presenting no new or threatening aspects last week, the feeling was generally one of optimism. Prosperous days with the car makers are at once reflected in the activities of the parts people, who practically to a man have all the business they can handle.

Bell Delivery Car by Sept. 1

1200-Lb. Vehicle on Same Chassis as Touring and Roadster Models

YORK, PA., July 19—The Bell Motor Car Co. will have on the market by Sept. 1 a 1200-lb. delivery car. The car will be built on the same chassis as the touring car. There will be two prices with and without electric lights and electric starter. The former figure will be about $775, the price of the touring car and roadster. The delivery car will be equipped with a Bosch magneto instead of the battery-coil ignition system as used on the passenger cars. It will also have a lower gear ratio. The bodies will be built at the plant of the York Body Mfg. Co., operated by the Bell Co.

The first Bell car was completed and appeared on the streets last week. The new Bell car is built in two models, a touring car and a roomy roadster, the price of both being $775. Features of the car are a one-man top, three-point suspension engine, crowned fenders, control levers above steering wheel with horn button in center of wheel, ample body room with pockets in doors, leather-covered instrument board, genuine leather upholstery, Hotchkiss drive, double universal joint, 112-in. wheelbase, demountable rims, weight of the car 2200 lb., 22 miles a gallon of gasoline, Atwater Kent ignition, worm driven from the camshaft, speedometer, rain ventilating windshield, self-starter run by inclosed silent chain. The body of the car will be dark blue, chassis, hood and fenders enameled black.

—

Warren Motor Truck Co. Formed

WARREN, OHIO, July 15—The Warren Motor Truck Co. has been capitalized at $25,000. The stockholders are Warren men who at a meeting elected the following directorate: R. B. Wick, William Wallace, D. L. Helman, R. A. Cobb, C. B. Loveless, G. C. Braden and G. F. Proctor. The directors elected officers as follows: R. B. Wick, president; C. B. Loveless, vice-president; L. L. Jones, secretary; G. C. Braden, treasurer D. M. Bell, general superintendent. The new company has purchased all of the machinery and equipment of the Standard Motor Truck Co. and expects to continue to manufacture trucks in accordance with plans of the former company.

—

New Midget Cyclecar Price $325

SPRINGFIELD, MASS., July 17—The Midget is the name of a new cyclecar that is to be built at Springfield, Mass. C. S. Root and L. E. Bartlett are the men behind it. The car weighs about 600 lb., and will sell for $325. The principal field for it, according to its builders, is in the mail delivery service, a specially constructed body having been designed for it. The motor is a two-cylinder, four-cycle type, and water-cooled. The bore is 3⅜ and the stroke 4 in. The engine develops 12 hp. A. L. A. M. rating. The friction type of transmission is used with three speeds forward and reverse. No axles are used on front or rear as a special arrangement of the springs does away with both. The wheelbase is 102 in. and the tread is 36 in.

—

Kelly-Springfield Adds Four New Trucks

SPRINGFIELD, OHIO, July 16—According to the plans of the Kelly-Springfield Motor Truck Co., this city, four new vehicles will be added to the line of Kelly trucks. This brings the Kelly line up to seven vehicles ranging in capacity from 1 to 6 tons. The new vehicles known as K-31, K-35, K-45 and K-60 are 1½, 2, 4 and 6 ton. In the two smaller the K-30 motor is used, which is the same as that formerly employed on the 1-ton model, and on the larger two the K-40 model motor is used, which is the same as that employed on the former 3½- and 5-ton models. Improvements have been made, but no radical changes are noted, the carbureter is now the Rayfield and the motor has the lower part of the crankcase cast in two parts.

—

McGookin Leaves Stewart-Warner to Join Springfield Body

DETROIT, MICH., July 17—Earl McGookin, who has been connected with the Stewart-Warner Speedometer Corp. of Chicago, for the last 12 years, and has been in Detroit during the past 7 years, being manager of the local branch, has resigned and will leave Aug. 1. At that time Mr. McGookin will become identified with the Springfield Metal Body Co., Springfield, Mass., which will establish a plant here in Detroit, for production business, exclusively. Mr. McGookin has purchased an interest in the Springfield concern and with him in the new plant there will be associated Joseph Boyer, Jr., and W. T. Fry. It will be several months probably before the local plant will be in operation. Five factories have thus far signed contracts and will be taken care of by the new local plant, the Paige-Detroit Motor Car Co.; the Maxwell Motor Co. and the Chandler Motor Car Co. being among these concerns.

S. A. Douglass will succeed Mr. McGookin as manager of the Detroit branch of the Stewart-Warner Speedometer Corp.

Must Abandon Credit System

American Manufacturers Must Learn to Risk Their Pay in S. A.

DETROIT, MICH., July 16—Until the American manufacturer is willing to forget the credit system and take a chance on his pay, American-made goods will not find a ready market in South America.

This is the opinion of Peter Steenstrup, who recently returned from an eight months' trip to Central America, the West Indies and South America in the interests of the Hupp Motor Car Co. Mr. Steenstrup last fall told Detroit manufacturers trade with South America would not prove a "gold mine" because of the war in Europe and he has returned from another trip below the equator convinced that the war has served to make it harder to establish commercial relations with the Latin-American countries.

How Manufacturers Err

"The war destroyed three things most necessary for the South American trade," said Mr. Steenstrup. "It took away the credit of the countries, the ships for bringing them goods, and deprived them of a chance to get products at the terms necessary for their business. Manufacturers in this country attempt to do business with the Spanish merchants on the same basis as they do with local dealers whose credit is established. Where the manufacturer demands gilt-edge security before he will ship an order, the Spanish merchant expects from three to nine months' credit. He is forced to sell the goods before he can pay for them.

"There is no Bradstreet or Dun in South America outside of one or two big cities. Such business cannot exist because the merchant considers inquiry as to his credit as an insult. The Spanish are honest, but they demand that they do business in their own way.

Chance for United States

"Study of the conditions of the people and country made the German and English successful in South America. The United States has the same chance, but she must start twenty years back and attack the problem in the same way. The English even now are selling goods in South America and are making a play for the business from the countries.

"It takes a salesman of tact and patience to do business in those countries. He must be willing to await the pleasure of the merchant and he must sell him what he wants to buy, not what the

salesman thinks he ought to purchase.

"When the wave of 'sell to South America' swept the country last fall, a good many merchants imagined they could dispose of products with ease. This cannot be done, because what we call necessities up here are luxuries in the tropics.

"The retarded civilization of the countries eliminates a large number of products that have a steady demand in this country. Cotton goods is the most universally required article in South America, and England seems able to negotiate that trade.

"Another reason that retards trade at this time is the fluctuation of the currency of the countries. In some of them the exchange rate for United States money is getting higher all the time. Merchants hesitate to buy on that account, fearing that by the time that they pay for the goods their currency will have dropped lower in its relation to our money.

"What the United States exporter needs is an understanding of conditions. He needs salesmen who know the country, and above all he needs the grit to tide him over a period of loss before he can build up a paying trade."

—

Marion and Imperial to Be Marketed by Mutual Motors

JACKSON, MICH., July 17—The Mutual Motors Co., this city, has acquired the exclusive sales right, good will, trade name, etc., of both the Marion and the Imperial cars and will hereafter market both of these through individual and separate departments of its own company instead of as heretofore through separate selling corporations.

The Mutual Motors Co. has heretofore confined its program to the manufacture of Imperial cars for the Imperial Automobile Co. and Marion cars for the Marion Motor Co., all of Jackson, Mich.

The Mutual company does not take over any of the physical assets or assume any of the obligations of either of the other two companies but has simply acquired the sole selling rights of both.

The Mutual will continue the manufacture of both lines, the Imperial line consisting of the Four which heretofore listed at $1,085 but listing now at $995 and the Six which heretofore listed at $1,285 but now listing at $1,185.

The Marion Light Six will continue as heretofore, but at a new list price of $1,185 instead of $1,250 as formerly.

The taking over of the sales ends by the Mutual Motors Co. does not in any way affect the field and dealer organizations of either line. In other words the Mutual will go right along supplying Imperial cars to Imperial dealers and Marion cars to Marion dealers just as the respective selling companies have done in the past.

Electric System on 1916 Monroe

Standard at $495 Instead of Extra—Refinements Only Changes in Car

FLINT, MICH., July 16—The 1916 Monroe car is now out and is being exhibited in many of the branch distributing agencies of the company. The car shows very little change from last year except for a few refinements and the fact that the electric lighting and starting are now standard at the purchase price of $495, whereas for 1915 they were extra equipment. It is featured by a streamline body, left drive, center control and full equipment including top, windshield, etc.

The car has a block motor with valves in the head, the 3 by 3.75 power plant delivering the drive through a 10.5-in. clutch to a three-speed gearset. Cooling is by thermo-syphon and the radiator is supplied with an auxiliary tank at the top. Lubrication is by a combination splash and pressure system. The oil is taken by pump to the connecting-rod, main bearings and timing gears. Nickel steel gears are used and the shifting lever is mounted directly at the rear of the gearbox, providing a direct control without intermediate linkage. The rear axle is semi-floating and torque is taken through a tube connected to the rear end of the gearbox by a forked yoke. The control instrument set is mounted on the cowl board.

Michelin Reduces All Tire Prices 10 Per Cent

NEW YORK CITY, July 20—A price reduction of 10 per cent, effective July 19, has been declared by the Michelin Tire Co., Milltown, N. J. The reduction covers the entire line. The old and the new figures on some of the more popular sizes of tires are given here:

Size	Old Price	New Price
30 x 3	$11.50	$10.40
30 x 3½	15.70	14.14
32 x 3½	18.00	16.25
34 x 4	24.50	22.00
36 x 4	26.25	23.75
36 x 4½	31.75	29.25

Heinze to Make Electric Starter

DETROIT, MICH., July 20—John O. Heinze, for nearly 5 years chief engineer of the Northway Motor & Mfg. Co., has resigned to go back into electrical work, having organized the J. O. Heinze Co., at Springfield, Ohio, to manufacture electric starters and other electrical apparatuses for automobiles.

Wm. Pflum, former manager of the National Cash Register Co. and later head of the Wagenhals Motor Co., and A. S. Knoblock, general manager of the Northway company are among those associated with Mr. Heinze in the new enterprise, which also includes some of the business men of Springfield and Dayton, Ohio. The new company is already incorporated for $500,000.

A new concrete plant has been secured at Springfield and Mr. Heinze states that the apparatus is to be manufactured completely, everything is to be carried on with the view of a high grade quantity output, 50,000 starters being planned for the first year with a working force of 350. Details of the starter design and of other apparatus will be forthcoming later.

—

Premier Company May Move Plant to St. Paul

MINNEAPOLIS, MINN., July 17—Frank E. Smith, of the Premier Motor Mfg. Co., Indianapolis, is here, looking over the ground for a factory site. He met a committee of the St. Paul Commercial Club.

INDIANAPOLIS, IND., July 20—*Special Telegram*—Upon his return from St. Paul, Minn., Frank E. Smith, trustee of the Premier Motor Mfg. Co., stated that the Premier company was seriously considering moving its entire establishment to St. Paul.

The rumor that a movement was under way has been persistently denied by the Premier company until to-day. Mr. Smith stated that St. Paul capitalists had made an attractive offer for the taking over of the company through the St. Paul Chamber of Commerce.

Mr. Smith would not make public any details, but said that the deal may be completed in thirty days. While he would make no statement as to the inducement offered at St. Paul it is believed that a site and buildings are included. Although Mr. Smith will not admit as much it is generally believed that the deal is all but closed.

—

Indiana S. A. E. Postpones to Sept. 24

INDIANAPOLIS, IND., July 17—A change in date and some added features is the latest news in regard to the opening meeting of the Indiana section of the Society of Automobile Engineers. The meeting was announced for Sept. 17, but it has been made a week later which will be Sept. 24. J. G. Vincent will be the main speaker of the evening, discussing twelve-cylinder.

J. E. Diamond, engineer of the Aluminum Casting Co., Detroit, will make an address on aluminum, while Mr. Vincent's address will be entitled, "Modern Tendencies in Motor Design" and will deal with the twelve-cylinder motor. Mr. Diamond's subject will be "Aluminum Pistons," very closely related to the twelve-cylinder subject.

21,826 Cars and Trucks in Colorado

Registrations During First Six Months of 1915 Show Increase of 5000 Cars, or 30 Per Cent Over Same Period Last Year, and 3395 More Than 1914 Total—Registrations Analyzed

By H. G. Hedden

DENVER, COL., July 15—A total of 21,828 automobiles, representing 197 different makes, is Colorado's registration for the first six months of 1915. This is a gain of more than 5000 cars, or 30 per cent over the same period last year, and a gain of 3395 cars, or 18 per cent, over the total registration for 1914, which was 18,433.

Besides heavy sales this year, two other factors are named by Secretary of State Ramer as helping strongly toward this increase. One was the system adopted by the retiring Secretary of State of starting the 1915 registration on the first of December instead of waiting till January, which was followed by Secretary Ramer with rigid insistence upon prompt registration throughout the state. The other has been Secretary Ramer's introduction of a license inspection system, which has brought in a large number of delinquents. In addition to these influences, extensive road improvements throughout the state and an earlier opening of the roads in general from snow and other hindrances to travel have played a part worth mentioning. Good

crops last year and good prospects for this year have greatly helped along the sales feature.

Denver Has 6705

Of the total number of cars in the state shown by the June 1 returns, 6705 were registered from Denver and 15,123 from the outside counties. Denver's increase is 585 cars above the total of 6120 for last year, or a gain of nearly 10 per cent.

With the prominent exception of Mesa County, on the western border, the eastern part of the State shows the main bulk of the increase. Mesa County has 396 cars for this year as against 316 for 1914, or an increase of 26 per cent.

Among the eastern counties leading in the gain are Arapahoe, joining Denver on the south, with a gain of from 210 to 346, or 64 per cent; Weld, two counties north of Denver, showing 1170 to 1430, or a gain of 22 per cent; Phillips, near the northeastern corner, with 220 to 162, or a gain of 35 per cent; and Baca, in the extreme southeastern corner, with a jump of 37 to 166, or a 348 per cent gain.

The only county not reporting any cars since the new state motor vehicle law went into effect two years ago is Dolores, in the extreme southwestern corner of the state, a thinly-settled, mountainous county. San Juan, also in the mountains and at an altitude where the snow stays on late, has not reported any registration so far this year, but reported three cars late in 1914. Some of the mountain sections have shown a pleasing increase, which is thought to be due in part to a substantial growth in the metal mining industry in the last year or two.

Classified according to style of car, horsepower rating and kind of motive power, the registration is as follows:

Class	Denver	Outside Counties	Total
Gasoline cars to 25 hp.	3,061	8,699	11,760
Gasoline cars above 25 hp.	2,495	5,495	7,990
Electric passenger cars	493	189	682
Steamers	64	105	169
Gasoline trucks	308	79	387
Electric trucks	33	4	37
Dealers' cars	251	552	803
	6,705	15,123	21,828

Total gasoline pleasure cars, classified: Denver, 5556; outside counties, 14,194; entire state, 19,750.

Of the 197 different makes represented in the state, the leading six rank as follows:

Make	Denver	Outside Counties	Total
Ford	2,132	6,286	8,418
Buick	323	1,266	1,589
Overland	468	1,076	1,544
Studebaker	324	635	959
Maxwell	415	499	914
Cadillac	330	428	758

Besides the regular Studebaker, there are also 315 registered as E. M. F., sixty-four being in Denver and 251 outside.

Secretary Ramer estimates that the total registration for 1915 will come close to 28,000, which will be an increase of 50 per cent over last year. He estimates that the total revenue for 1915 from all motor vehicles and drivers' licenses will be approximately $125,000, as against $80,000 in 1914. More than $100,000 of this will probably be available for road work through the state and county highway funds, the net motor vehicle license revenue being divided equally between the state highway fund and the road funds of the respective sixty-two outside counties individually in proportion to the fees collected by each county. Last year the net amount so divided for road work was $76,600.

—

King Adds Three-Passenger

DETROIT, MICH., July 20—In response to a demand for roadsters, the King Motor Car Co. has added a three-passenger body mounted upon the eight-cylinder chassis, which has a wheelbase of 113 in. The roadster sells for $1,350, the same as the touring car.

Improvements have been made in the chassis itself, the bore having been increased from 2¾ to 2⅞ in. and to accommodate the larger volume of gas, the valve ports have been increased in size and a larger intake manifold fitted with an improved type of Zenith carbureter.

Roominess has been made a feature in the roadster, some of the principal dimensions being: dash to front seat, 20½ in.; floor to top of cushions 13 in.; thickness of cushions 8 in.; width of seat, 43 in.; front of seat to back, 18 in.; top of cushion to top of back seat, 19 in. Tires are 33 by 4 non-skid on the rear with one extra rim as part of the regular equipment.

—

Brush to Assist Scripps-Booth

DETROIT, MICH., July 20—Alanson P. Brush, of the Brush Engineering Association, has been retained as consulting engineer for the Scripps-Booth Co. on its 1916 models. W. B. Stout, chief engineer, also receives the added title of advertising manager of the Scripps-Booth concern, to take effect Aug. 1.

By these changes the position of the Scripps-Booth Co. in its unique field of design is further strengthened. Mr. Brush is well known in engineering circles, and his automobile experience dates back to his designing work on the single cylinder Oldsmobile and Cadillac cars. He also has consulting connections with Moline and Ferro companies.

Bay State Fees Over $1,000,000

83,868 Cars and Trucks Registered—Gain of 27.5 Per Cent Over 1914

BOSTON, MASS., July 17—Massachusetts automobilists have poured into the state coffers more than $1,000,000 for the first six months of this year, and the registration figures will exceed 100,000 for the year without any doubt. Even now with the year half gone it takes at least half an hour to get a car registered at the Highway Commission's headquarters, and every day there is a line extending out into the hallway waiting to get numbers. For the first six months of 1915 there were 83,868 machines registered in the Bay State. That was an increase of 19,252 over the same period of 1914, and it is 6652 more than had been listed for the entire year of 1914. About $200,000 more than was gathered in for the first six months of last year has been taken in for the same period this year, and it is about $34,000 more than was secured for the full year of 1914. Before the season ends it is expected that at least $1,250,000 will be paid the state by motorists.

The increase shows an average of 27.5 per cent above the figures of last year, a very big gain which shows that New England is prosperous. The number of people securing driver's licenses is jumping rapidly until now about one in every twenty-six Massachusetts residents is allowed to drive a car. This increase is about 27 per cent, and when the year ends about 125,000 licenses will be in the hands of Bay State operators. The trucks have gained faster than cars. The dealer class, too, shows a good gain, there being 1653 registered so far this year to 1145 for the same period a year ago.

—

Kentucky Gains 3743 Cars

LOUISVILLE, KY., July 16—According to Hugh Ramsey, deputy commissioner of motor vehicles, 15,500 automobiles are now registered in the State of Kentucky, a gain of 3743 since Jan. 1, 1915, when the official records showed the registration to be 11,757. It is predicted that a total of more than 22,000 cars will be registered by Dec. 31.

Massachusetts Registrations for 1914 and 1915

	Jan. 1 to July 1, 1914	Entire Year, 1914	Jan. 1 to July 1, 1915

Renewals, operators and chauffeurs	43,418	72,674	49,443
Examinations	3,885	7,497	5,317
Receipts	$781,965.35	$965,669.59	$999,524.90

National Rubber to Move Plant

Work Begun on 1000 Ft. Structure in Williamsburg, Pa.—Efficient Layout

WILLIAMSBURG, PA., July 19—The National Rubber Co., with factory and main offices now in Pottstown, Pa., broke ground here to-day for the model daylight factory which the company plans to have completed and in actual operation by Jan. 1.

Since the first of the year the business of this company has increased so rapidly that its factory facilities in Pottstown are no longer adequate to meet the demand. Rather than attempt to build additions to the present plant, it was decided to build an entirely new and model factory which would be able to turn out at least 1000 tires and tubes a day.

The National people have been quietly looking for a desirable location for over two months and after looking over the offers and advantages offered by 150 different cities finally decided upon Williamsburg because of its natural advantages.

Ten acres of ground which was found suitable were secured on a railroad siding and next to the Blue Juniata River from which it will be possible to obtain free water and power—two important items for a rubber factory.

The factory is laid out to secure the highest possible efficiency in manufacturing. The main building is to be 1000 ft. long and 65 ft. wide and one story high. The construction is of Ponds continuous steel sash throughout, insuring perfect natural light and ventilation. There will not be a pillar or post in the entire 65,000 ft. of floorspace.

It is planned to have all the machinery independently driven by electricity in order to eliminate all overhead belting and shafting, the factory being arranged so that the raw material will be received at one end of the building and from there travel through the long structure without once moving backward or requiring any duplicate handling.

In addition to the main building there will be separate buildings for the powerhouse, the machine shop and the office building. The powerhouse is to measure 40 by 40, the machine shop 65 by 120 and the office building 50 by 50.

The factory in Pottstown will continue in operation until the new factory is completed. The machinery will then be moved to Williamsburg and operations resumed, it is hoped, within a week after leaving the old factory. Considerable new machinery is to be purchased.

The National Rubber Co. is incorporated for $2,500,000 and employs over 200 men.

—

$1,000,000 Plant for Overland in St. Paul

ST. PAUL, MINN., July 15—The Willys-Overland Co., Toledo, Ohio, will erect a branch factory office building, warehouse and storage yards in St. Paul, costing $1,000,000. Work will begin in the near future on the plant on University Avenue, adjoining the Illinois Steel Co. plant.

The company has frontage of about 500 ft., with ample room for expansion. The plant here will assemble and ship cars to all Overland agencies west as far as the Pacific Coast. The plant will employ about 5000 people.

—

Metal Prices Lower

NEW YORK CITY, July 20—With the exception of metal prices, quotations in the markets this week remained unchanged. Lead, tin, electrolytic copper and antimony, were lower. Lead dropped to $5.55 a 100-lb. on Friday and held at that price until the closing on Monday. The metal is being freely offered at that price, but the buyers are looking forward to a continuation of the downward movement and are not taking much metal. The tin market prices fluctuated last week, the highest mark being $38 on Tuesday. The market continues its downward course under the pressure of the weak and heavy markets at London and the Straits. Electrolytic copper showed a fractional loss and it is predicted that a further reduction may take place.

1916 Allen Price $795

FOSTORIA, OHIO, July 21—The Allen Motor Co., this city, has announced the Allen "37" for 1916 selling at $795, the same price applying to both the roadster and the touring car. The 3¾ by 5-in. motor develops 37 hp. The motor is long stroke and is made by the Sommer Motor Co., Bucyrus.

Other features are Stromberg carbureter, Westinghouse electric system for starting, lighting and ignition, Stewart-Warner vacuum fuel feed system with tank hung at rear, full floating rear axle, pressed steel housing, 12-in. brakes with pressure equalizers, 55-in. long underslung rear springs, 112-in. wheelbase, 32-in. wheels, and a one-man top.

—

No Goodrich Common Dividend

NEW YORK CITY, July 15—Despite the fact that earnings of the B. F. Goodrich Co. are expected in some quarters to show at the rate of 10 per cent for the common stock, it is stated that officers of the company will recommend at this month's meeting of the directors, July 28, that no dividend be declared on the common stock. The company intends to build up an immense surplus before dividends are resumed.

—

Buys Entire Havers Factory Stock

CLEVELAND, OHIO, July 15—R. C. McLean, president of the M. & M. Co., 480-500 Prospect Avenue, has purchased the entire stock and equipment of the Havers Motor Car Co., Port Huron, Mich., from the receivers.

Mr. McLean is preparing to put the entire equipment and stock on sale at his warehouse, 515 Huron Road.

—

Racine Co. Files Petition

RACINE, WIS., July 15—The Racine Drop Forge Co., this city, filed a voluntary petition in bankruptcy on July 17, admitting liabilities of $9,462 and assets of $3,553. The concern was identified with the motor and car industry and transacted practically all of its business in this line.

—

National Spring & Wire Adds

ALBION, MICH., July 16—About $100,000 is to be spent by the National Spring & Wire Co., manufacturer of seat springs, in enlarging its plants here and

in Windsor, Canada. The additions to the local plant will consist of a two-story building, 294 by 60 ft., which will be an enlargement of the machine shop. A small section of the new structure will be only one-story high and will be used for enameling ovens and dip-room. Another addition, 146 ft. long now nearly completed, will include the new offices and tool rooms. A new building recently completed as a storeroom, will be fitted with machinery and become a part of the machine shops.

—

Great Western Enters Six Field

PERU, IND., July 20—The Great Western Automobile Co., this city, which has for years been manufacturing a four-cylinder car, has entered the ranks of the six-cylinder builders. Fitted with a five-passenger body and mounted on a chassis of 112-in. wheelbase, the new car sells for $1,185 f.o.b. Peru. It is provided with a 3- by 5-in. power plant and is featured by a body of streamline design with divided front seats and roomy tonneau. It is low-hung and has adequate storage space. Curtains are Jiffy, secured to the bows of the one-man top.

The tool box and battery box are under a hinged door in the floor in front of the driver's seat, allowing the driver to reach any of the tools without disturbing the passengers. Luggage compartments are placed under the tonneau floor, there being two, each large enough for two suit cases. The gasoline tank is in the rear along with the tire carrier which is patented, it being necessary to remove but one screw to remove the rim and tire.

General Motors Common Gains 32 Points on Dividend Rumor —Overland Another Feature

NEW YORK CITY, July 19—Securities closed on Saturday with some very substantial gains. The market as a whole showed a most remarkable advance, considering the fact that a big reaction was expected. Firestone common is now quoting at between 506 and 512, approximately 300 points higher than this time last year and General Motors common, which showed a record gain of 32 points last week, has shown a 100 per cent gain since last July.

Willys-Overland common and preferred gained 14 and 1½ points on the strength of the new Willys-Knight announcement. International Motors came to the fore again Saturday when its common rose to 17 and its preferred to 43, respective gains of 4½ and 8 points.

Tire issues, with the exception of Firestone, were not so prominent last week. All three Kelly-Springfield issues showed drops and U. S. Rubber preferred also showed a decline. Goodrich preferred made a slight gain of 1-2 point.

The Detroit issues were steady with a few gains. General Motors common showed a 32½-point gain, in sympathy with the Wall Street prices. Its preferred went 3¼ points. The rest of the changes ranged in gains from 1 to 3¾ points. In the inactive stocks, the only change that occurred was that of Canadian Ford, which was 75 points.

—

Pope's Westfield Plant Sold

HARTFORD, CONN., July 21—*Special Telegram*—The Westfield plant of the Pope Mfg. Co. was sold at public auction Tuesday afternoon to H. Preston Coursen of New York, representing Wilbur C. Walker of the Hartford Motor Car Co. and a former officer of the Pope company, and Scott McLanahan of New York for $725,000. There was no other bidder. A certified check for $25,000 was deposited and the balance is to be paid within fourteen days from the time the sale is confirmed by the court.

The sale includes all the real estate, fifteen acres, the big factory buildings, machinery and equipment of the plant and the cash on hand with the receivers July 19, amounting to $229,186.65. The purchasers assume the liabilities of the receivers incurred in the operation of the plant.

Wilbur C. Walker will undoubtedly be the head of the establishment in the future. Associated with him will be his brother Charles E. Walker of the Walker Barkman Mfg. Co., this city. Several Hartford people will be financially interested.

A new company will be formed and it is understood that the capitalization will be $1,600,000 of which $800,000 will be common stock and $800,000 preferred. The outside financial interests which have underwritten the purchase price will no doubt be retired.

To Continue Briggs-Detroiter

Detroiter M. C. Co. Formed —$48,000 Bid for Plant Refused by Trustee

DETROIT, MICH., July 17—The business of the Briggs-Detroiter Co. is to be continued, according t a statement made by A. O. Dunk, president of the Puritan Machine Co., who purchased the personal property of the bankrupt automobile company in the bankruptcy court July 15. The Detroiter Motor Car Co. has been formed with Mr. Dunk as president and it is said that officials of the new concern are now operating the service, parts and manufacturing departments. Frank M. Eldredge has been appointed advertising manager.

The real estate, consisting of the plant and land, was also offered for sale by the trustee, the Detroit Trust Co., but as only $48,000 were offered, and this was considered too low, the offer was not accepted. It had been provided that the trustee could sell the property for not less than $75,000 without the referee's approval, also that no offer for less than $63,000 was to be accepted without first giving notice to the creditors. A first dividend of 10 per cent is to be paid soon.

In the report furnished by the Detroit Trust Co., receiver for the bankrupt Briggs-Detroiter Co., the details as to the assets of the latter concern are given as in the accompanying table.

The Briggs-Detroiter Co. made and shipped 1100 four-cylinder cars in 1912. 2750 in 1913; 1600 in 1914. While, until it went into the hands of the receiver this year, it had made and shipped 450 four-cylinder cars and 280 eights.

Claims All Mercedes Cars Were Made for War Help

LONDON, ENGLAND, July 19—A statement has been made by a former German prisoner who has just arrived in this city that all German Mercedes cars were built for war help. C. B. Pray, an American automobile mechanic, states that his work up to the time of his arrest brought him into daily contact with the German Mercedes car. The chassis of every car of the 1912, 1913 or 1914 models was perforated at the sides with two sets of four holes each, at equal distances from the front and rear, for the purpose of riveting over the chassis frame a plate heavy enough to bear a weight of 1000 kg.

In May and June, 1914, the cars were called in for inspection and returned with the plates mentioned duly affixed without the owners' knowledge of what had been done. When the cars were requisitioned for war only the tops had to be ripped off and guns and searchlights mounted in their places.

Oldfield Gets Delage Racer

CHICAGO, ILL., July 20—*Special Telegram*—One of three Delage cars built for the 1914 French Grand Prix arrived in Chicago to-day and was turned over by its purchaser, David G. Joyce, chairman of the A. A. A. Touring Bureau, to Barney Oldfield, who will enter at Elgin and fall speedway meets.

Oldfield this afternoon challenged Resta to a 100-mile match race to be run on Chicago Speedway Aug. 7, and posted a $2,500 side bet.

Three Duesenbergs at Des Moines

DES MOINES, IOWA, July 17—Fred Duesenberg, builder of the Duesenberg racing cars, announces that O'Donnell, driving a Duesenberg with 360 cu. in. of cylinder displacement, will go out after a new 100-mile record on a mile track at the formal opening of the new Des Moines Speedway on July 25 when Barney Oldfield, driving a Christy front drive car, will go after records for the 1, 5 and 10 mile distances. Earl Cooper will come to Des Moines with O'Donnell for the July 25 event.

Three Duesenberg cars are entered for the 300-mile event on the new speedway on July 31. Two of the drivers for Duesenberg will be O'Donnell and Alley. Oldfield also is entered in the 300-mile event as well as De Palma. Rickenbacher, may be in the race at the wheel of a Duesenberg since the two Maxwell entries for the event have been withdrawn.

Tent for Indianapolis Show

INDIANAPOLIS, IND., July 15—The Indianapolis Automobile Trade Assn. will use a tent, 150 by 330 ft. in size, for the automobile show at the State fair, Sept. 6.

Stutz Not to Quit Racing

Co. to Enter Three Cars at Elgin—Disapproves of DePalma's Plan

CHICAGO, ILL., July 17—E. C. Patterson of Chicago, backer of Ralp DePalma in his racing campaign, to-day purchased one of the 300-in. cars made by Harry Stutz for this year's contests and driven by Howard Wilcox at Indianapolis and Chicago. Before to-day's deal was consummated, the car was entered in the Elgin road races by DePalma, who has secured Caleb Bragg to pilot it.

The outright purchase of the car by Patterson is the result of a deal in which Stutz offered DePalma the management of the Stutz team. The Italian consented to take over the cars provided he could campaign them with his Mercedes but the Indianapolis maker refused to agree to any such arrangement. The sale of the Stutz to Patterson does not mark the retirement of the Stutz company from racing. It has two cars on hand, one at the factory and the other on the Pacific coast, and is building a third at the present time. All three cars will be entered at Elgin, according to Stutz, and in the fall speedway meets.

1916 Tacoma 1-Day Event with 300 or 350-Mile Race

TACOMA, WASH., July 15—It was decided by the directors of the Tacoma Speedway Assn. at a meeting held July 12 that Tacoma's automobile races for 1916 will consist of one big race of 300 or 350 miles, and the Inter City race, both to be run on one day and with the big sum of $10,500 in prizes for the one main event alone.

After going over the financial results of the recent races the officials expressed themselves as well pleased with the receipts of the races this year.

In addition to deciding upon the one day of racing with the two events, the directors decided to offer an additional cash prize at the end of each 100 miles of the main event to the driver who is leading the race at that time. This is to be done in order to insure a faster race and prevent any possible lagging of the drivers.

The chief reason for deciding upon the one day of racing is that to make speed in the main race many cars are so badly damaged that they cannot compete in the second day's events. The directors wish the Montamarathon to be a race of speed in which the best drivers of the country will put their cars and individual cunning, prowess and endurance.

For the Inter City race the prizes awarded will be separate from those of

the Montamarathon. Dates for the Tacoma races will be fixed at the fall meeting in October of the directors of the Speedway Assn. of America.

It was also decided to put a heavy guard rail about all the curves on the Tacoma speedway before the 1916 races.

—

To Hold Circuit of Twenty-five Races

UNIONTOWN, PA., July 15—For the purpose of holding a series of races in Pennsylvania and adjoining States, a number of men, including I. P. Fetterman, A. C. Smith of Pittsburgh, G. B. Gardner of Beaver, and C. W. Johnson of Uniontown, recently attended a meeting held at the Standard Auto Garage, this city, where contracts were signed to give permission for their cars to be entered in every race that will be held by the Automobile Racing Association this season. This association will receive its sanctions from the A. A. A.

—

Exposition Automobile Week

SAN FRANCISCO, CAL., July 14—Chas. B. Lewis, who for some time has had charge of some of the exhibits in the automobile section of the Palace of Transportation at the Exposition here, has recently been made president of the Automobile Association of the Transportation Palace P. P. I. E. This association is now making arrangements for an automobile week in September.

—

Denver-to-Cheyenne at 41.2 M.P.H.

DENVER, COL., July 17—A new record for the 112 miles between Denver and Cheyenne was established to-day in the road race staged by two Denver dailies with the aid of the Denver Motor Club. The event was an informal unsanctioned contest and was a kind of Denver greeting to the Cheyenne Frontier Day Celebration which opens next week. J. J. Mellwee drove a Hudson six the 112 miles in 2 hr. and 43 min. 29.3 sec., a speed of 41.2 m.p.h. as compared with the old record of 2 hr. and 49 min. Leon Nelson, driving a Metz, was second in 2 hr., 54 min. and 45 sec. The Saxon was third in 3 hr. and 8 min. Twenty-five cars were entered in the contest.

—

24-Hours Saxon Parts Service

DETROIT, MICH., July 15—At the dinner given to the Saxon dealers who came here to take part in the economy run and driveaway which was held to-day, factory manager C. C. Cross announced a 24-hr. service on parts.

President H. W. Ford addressed the dealers principally pointing out the importance of economy runs and the facts they demonstrate. Chief engineer R. E. Hale spoke from an engineering point of view about the Saxon car.

The driveaway was pronounced a great success, 105 dealers start[illegible]

Only Passenger Cars in Yellowstone

Regulations Fixed—$5 Fee for Runabouts, $7.50 for 5- and $10 for 7-Passenger Cars

WASHINGTON, D. C., July 17—Complete regulations governing automobiles in the Yellowstone National Park from August 1, the date on which the park will be thrown open to the use of automobiles, have been issued by the Department of the Interior. Only passenger vehicles are admitted, motorcycles not being allowed in the park. Tourists entering the park are required to secure tickets of passage which cost $5 for runabouts, $7.50 for five-passenger cars and $10 for seven-passenger cars. Such fees are charged for each trip through the park. Speeds are set at 12 m.p.h. ascending grades, 10 m.p.h. descending and 8 mi. when approaching sharp curves. On good roads with straight stretches and with no teams nearer than 200 yards a speed of twenty miles is permitted.

Automobiles while in motion must keep 100 yards apart except for purposes of passing other cars which is only allowed on level and straight stretches. Cars must keep their gears in mesh constantly except when changing; in other words, coasting is not permitted.

Horse vehicles are really given the right of way and when teams, saddle horses or park trains approach the automobiles are required to take the outer edge of the roadway regardless of the direction in which they are traveling. In case of road difficulties automobiles will be backed or otherwise handled to permit the horse teams to pass safely. Automobiles must pass animals on the road at not greater than 8 m.p.h.

Schedule by Checking Stations

In order to see that all automobilists using the park do not exceed the speed limit a complete schedule of travel throughout the park has been adopted and a series of checking stations established at the hotels so that the park authorities can determine if an automobile is exceeding the speed schedule, in which case he is fined fifty cents per minute for each of the first five minutes he is ahead of schedule at any point; $1 per minute for each of the next twenty minutes, and $25 fine or ejection from the park or both, in the discretion of the park superintendent, for being more than twenty-five minutes early.

To Test Brakes

All automobilists will be given a preliminary examination of brakes, tires, etc. The brake test will require skidding of the rear wheels on either set of brakes. Gasoline can be secured at regular stations in the park.

In case of accidents to the car on the park roads the cars must be taken off the road, or if this is impossible they must be placed at the outer edge of the road. Cars will not be permitted for use on local trips around Hot Springs formation or other points off the main roads. Horns must be sounded on approaching curves. Automobiles may leave the park by any one of the authorized routes.

—

Beardsley Travels 1500 Miles in 14 Days on 14 Charges

LOS ANGELES, CAL., July 13—Traveling more than 1500 miles in 14 consecutive days on fourteen charges, a stock model Los Angeles-built Beardsley electric has completed one of the most remarkable electric runs ever held in the West. On the entire run, the average was 107½ miles to the charge.

The announcement was recently made by the Beardsley Electric Co., of this city that a stock model brougham would attempt to run 1000 miles in 10 days on ten charges. To show the ease of operation, Mrs. V. S. Beardsley was appointed pilot for the test and the press appointed ten observers, all women, to accompany the car on each day of the run.

In 10 days Mrs. Beardsley had run up a total of 1066.3 miles, every day's run exceeding the 100-mile mark.

—

Racing for South America

NEW YORK CITY, July 21—Automobile racing is to be introduced in several South American cities within a year. A 2½-mile track, it is said, will be built. Plans for a purse of $100,000 for its first race, which is to be over a distance of 500 miles, have been offered. Speedways will be constructed in a number of cities of South America.

—

300-Mile Track Race for Juarez

EL PASO, TEX., July 20—The El Paso Auto Club has applied to the A. A. A. for a sanction for a 300-mile automobile race to be run over the track of the Jockey Club Juarez, in Juarez, Mex., the last week of September.

It is the intention of the promoters of the race to bank the turns heavily so as to make them safe.

Purses aggregating $5,000 will be hung up to be competed for in the several races which, in addition to the proposed 300-mile race, will make up the three-day program now in mind.

—

Forty Inter-States a Day

MUNCIE, IND., July 16—The Inter-State Motor Co. to-day manufactured forty cars which is double the capacity of two weeks ago.

"Get Cash, Pay Cash"—Ford

Answers Bankers' Questions on Country Bank Problem as to Automobile Loans

MILWAUKEE, WIS., July 19—Henry Ford told the Wisconsin Bankers' Assn. at its annual convention in Milwaukee, July 13-17, what he thinks of the responsibility of motor car builders to the bankers of the country. In reply to the question, "The Country Bank's Problem As to Automobile Loans," Mr. Ford promulgated a "Get Cash, Pay Cash" slogan and struck straight from the shoulder on a topic which has apparently been of deep concern to bankers of the country since the motor car was first built in quantities.

Does Not Believe in Credits

"You say that you feel automobile manufacturers will soon find it necessary to assist in financing the sale of their product in some such way as the manufacturers of farm machinery are obliged to do," says Mr. Ford's letter. "So far as I am concerned, I have never been able to determine just what is the difference between paying your debts now or putting them all off to some future time. Why should time be extended on farm machinery or motor cars until they are practically worn out, any more than time should be extended on the purchase of horses or cattle? I know that time is extended on cattle where they grow in value themselves, but I do not know of any system whereby horses are purchased on credit and paid for after they are dead or the best part of their usefulness worked out.

"It has always seemed that this putting off the day of payment for anything but permanent improvements was a fundamental mistake.

"The Ford Motor Co. is not interested in promulgating any plan which extends credits for motor cars or for anything else," continues Mr. Ford. "The farmer gets cash for everything he sells, and yet expects to buy everything on credit. The country banks complain about our taking the money out of their districts. The farmers have the habit in many sections of the country of holding their crops for better prices and then they want the farm implement manufacturer and the banks to carry the load while they are waiting for better prices.

"This trouble you speak of seems to be largely due to the farmers themselves, and I can see no reason why they should be encouraged in this. The country bankers should not expect to make more than a reasonable return on their capital and therefore should not expect to carry more loans, whether on farm implements or on motor cars, than their capital and deposits permit. If the country banks want to carry these loans themselves, why not increase their capital stock to enable them to do so? It is my opinion that many of the country banks could sell a good deal of their paper to Milwaukee banks.

"The manufacturer should have cash as well as the farmer. The manufacturer pays out enormous sums in cash for wages and he gets no extended credits on any of his material. The manufacturer cannot pay cash to labor; cannot pay for merchandise in thirty days and extend credits to purchasers of motor cars for months and sometimes years."

The discussion on motor car loans during which the Ford communication was read was one of the most important before the convention. It was brought out that to-day in Wisconsin there is an investment of $70,000,000 in automobiles, 90 per cent of which has been withdrawn from banks, either by withdrawal of deposits, money borrowed or notes purchased. This condition has caused a shortage of capital.

Semaphore Traffic Plan Tried in New York

NEW YORK CITY, July 20—A system of regulating traffic by semaphores was tried yesterday in Fifth Avenue between Thirty-third and Thirty-seventh Streets and was pronounced successful.

A semaphore at Thirty-fourth Street regulated similar semaphores on the four other crossings and traffic was permitted to travel first north and south, then east and west for a period estimated as that required for an automobile to travel the five blocks at 12 m.p.h.

A change was made also in the turns and automobiles traveling north and wishing to turn west passed south of the semaphore instead of north after reaching the middle of the street.

—

S. A. E. Could Aid on War Board

NEW YORK CITY, July 21—Automobile engineering circles are widely aroused over the fact that the Society of Automobile Engineers has not been invited to select two members to serve on the proposed naval advisory board which Secretary Daniels is forming, and to which eight engineering societies have been invited to select two delegates each. There is no question but that the S. A. E. could lend valuable aid, particularly in the motor transport work, which is proving to be such a potent factor in the present war. In England the Institute of Automobile Engineers has been a great assistant to the navy and war departments and in America the S. A. E. can lend similar aid. Standardization is a work that is needed and the S. A. E. has demonstrated its leadership in the matter.

Unquestionably the war department will follow the steps of the navy in organizing a war department advisory board and on such a board the automobile engineer would be of peculiar value because of the importance of motor transport not only for troops and commissary, but also heavy artillery, etc.

—

Lux Wins Chalmers Sales Contest

NEW YORK CITY, July 19—At the conclusion of the Chalmers Spring Sales Contest yesterday, the most successful sales contest ever conducted by this company, Leo Lux, Chalmers dealer at Wadsworth, Ill., was awarded a five-passenger Light Six touring car, the grand sweepstakes prize. Mr. Lux made the remarkable record of selling 697 per cent of his quota between April 19 and June 30.

—

Rajah Plugs on 1916 Cadillac

DETROIT, MICH., July 19—The Cadillac Motor Car Co. has contracted with the Rajah Auto Supply Co., Bloomfield, N. J., for its spark plug equipment for 1916. This means that some 130,000 to 150,000 Rajah plugs will be supplied.

—

Garlent King Factory Manager

DETROIT, MICH., July 19—J. E. Garlent has been appointed factory manager of the King Motor Car Co. and will cooperate with assistant general manager J. F. Siegfried. Mr. Garlent was until recently general superintendent of the Hupp Motor Car Co.

—

Stevens-Duryea Parts Business Intact

CHICOPEE FALLS, MASS., July 19—The parts business of the Stevens-Duryea Co. is still intact and the manufacture and sale of parts continue under the management of Wm. M. Remington, Chicopee Falls.

—

Rouze Knox Motors Sales Manager

SPRINGFIELD, MASS., July 15—C. F. Rouze has been appointed sales manager of the Knox Motors Associates, the sole distributors of the products of the Knox Motors Co. Mr. Rouze succeeds H. F. Blanchard.

—

Drumpelmann with Chalmers

DETROIT, MICH., July 20—The Chalmers Motor Co. has appointed W. J. Drumpelmann as its Eastern district manager. Until quite recently Mr. Drumpelmann was with the Olds Motor Works, Lansing.

—

Wilcox with Republic Truck

DETROIT, MICH., July 19—G. D. Wilcox, for 4 years advertising manager of the Regal Motor Car Co., has become advertising manager of the Republic Motor Truck Co., Alma, Mich.

Factory Miscellany

To Manufacture Accessories. — The Fitzgerald Noble Co., Richmond, Cal., is to build a factory to manufacture automobile accessories.

McCurdy to Make Tractors—W. H. McCurdy, president of the Hercules Buggy Co., Evansville, Ind., will organize a new concern for manufacturing farm tractors.

To Make Tops—The National Limousine Top Corp., Buffalo, has leased factory premises at 41 Letchworth Street, and is equipping it for the manufacture of automobile tops, etc.

Burd Increases Factory—The Burd High Compression Ring Co. is beginning the installation of machinery in an additional new factory building, containing 30,000 sq. ft. of floor space.

Standard Tire Begins Plant—The Standard Four Tire Co., Keokuk, Iowa, of which W. J. Richards is general manager, is about to begin construction of a factory for the manufacture of tires.

Rands' $20,000 Addition—The Rands Mfg. Co., Holden Avenue, Detroit, Mich., manufacturer of windshields, has awarded the contract for the construction of a three-story concrete addition to its plant, to cost $20,000.

Ford Band Goes to the Coast—The Ford motor band, consisting of fifty-five skilled musicians, left for an extended tour to the Pacific Coast on July 20. Every member of this band is on the factory payroll of the Ford Motor Co., and this transcontinental tour to the San Francisco and San Diego expositions is complimentary.

Service Gear & Machine Co. Incorporated—The Service Gear & Machine Co., Reading, Pa., was recently incorporated in the State of Pennsylvania for $20,000. The company is manufacturing parts for service stations and parts jobbers, and makes a specialty of manufacturing transmission gears, bevel gears, axle shafts, piston pins, etc.

Wadsworth Buys Land—The Wadsworth Mfg. Co., Detroit, Mich., recently organized with a capital stock of $250,000, has purchased a large tract of land on Jefferson Avenue, on which the company will erect a modern four-story factory, 240 by 260 ft. The firm manufactures and sells automobile tops, bodies and accessories.

Herbrand to Add—The Herbrand Co., Fremont, Ohio, will build a $20,000 addition to its plant. An enlargement of the factory has been made necessary by large orders for automobile parts from the Ford Company of Detroit and other concerns. The company is so rushed with orders that a three-shift working schedule has been adopted.

To Make Gasoline Device—The Stephan Mfg. Co., Freeport, Ill., has been incorporated and will sell automobiles and accessories. Fred Rice is president; Howard Rice, vice-president; A. M. Stephan is secretary, and Mrs. B. B. Stephan, treasurer. A gasoline saving device, invented by Secretary Stephan will be manufactured and distributed.

Atlas Foundry to Build—The Atlas Foundry Co., Detroit, Mich., manufacturer of castings for automobile parts, will erect a large factory on Artillery Avenue, to be 270 by 85 ft., and of steel frame construction, at an estimated cost of $25,000. The foundry will be equipped with a traveling crane of five tons capacity, and other modern improvements.

McGraw Tire Adds—Expansion of the business of the McGraw Tire & Rubber Co., East Palestine, Ohio, will mean the employment of probably 1000 more people. The company has asked the Municipal Council to vacate several streets in the vicinity of the plant, so that large additional buildings may be erected. The company is composed of local and Pittsburgh men.

Hartford Machine Leases Plant—The Hartford Machine Screw Co., Hartford, Conn., has leased the brick plant formerly occupied by the Hartford Dairy Co. and more recently by the Pratt & Cady Co. Alterations are now being made and will be completed about the middle of August, at which time the company will move in new machinery for light manufacturing. The building is of brick, two stories and basement, and comprises 48,000 sq. ft. of floor space.

To Make Steel Specialties—Howard Mann, who recently purchased the abandoned Burrell factory in Bradley, Ill., has commenced the manufacture of steel specialties for automobiles. The old plant has been improved and altered, 10,000 sq. ft. of concrete flooring being laid. Mann has contracts amounting to $50,000, which will take the output of the first year. New machinery has been installed at an expense of $3,000. A new line which may be added later will give employment to 150 additional men.

Pittsfield Coil in New Plant—The Pittsfield Spark Coil Co., Dalton, Mass., has secured a brick factory, three stories and basement, in Pittsfield, Mass., the city where the company originated twelve years ago, and will move the plant to the new quarters immediately. All correspondence, inquiries and orders hereafter should be sent direct to the Pittsfield Spark Coil Co., Pittsfield, Mass., to avoid delay, or ordered from any of the branches of the Western Electric Co., who are the distributing agents of the Pittsfield Spark Coil Co.

The Week in  the Industry

White in Vulcanizing Business—C. E. White, owner of the Model Vulcanizing Works at Flower and Twelfth Streets, Los Angeles, Cal., has formed a partnership with H. H. Holmes and opened a tire house and vulcanizing plant at 912 South Olive Street, doing business under the name of the Olive Vulcanizing Works.

Fishleigh Joins Los Angeles Apperson—W. T. Fishleigh, until recently at the head of the automobile department of the college of engineering at the University of Michigan, has been appointed head of the technical department of the Los Angeles Apperson branch, which controls the entire California, Arizona and Nevada territory.

Take on Grant Six—Ralph Jernberg and F. E. Wheeler have formed a company to handle the Grant six at Worcester, Mass., with salesrooms at 18 Wellington Street. Mr. Jernberg was formerly with J. C. Harvey, Worcester agent for the Haynes, and Mr. Wheeler was a member of the sales force of the Grant company of Boston, Mass.

MacDonald Gets the Jackson—J. A. MacDonald, who resigned as president of the Providence Motor Car Co., Providence, R. I., the company having temporarily left the automobile business, has taken on the agency for Jackson cars in Rhode Island. He is making his headquarters at the Broadway Garage on Dean Street. The Providence Motor Car Co. will continue its tire business at a new stand on Empire Street.

Garage

Grand Rapids Station Opens—The Peck Auto Sales Co., Studebaker agent, Grand Rapids, Mich., has opened its new service station and repair shop, Island and Ionia Avenues.

Des Moines Co. Moves—The Leachman-Claiberne Co., Des Moines, Iowa, will move this fall from its present location at Eighth and Mulberry Streets to new quarters at Eleventh and Locust Streets.

Decatur Garage Opens.—B. H. Asher and A. L. Arnold have opened a new garage and repair shop in Decatur, Ill., specializing on the Ford. The firm has leased the building at 712 North Broadway.

Cal. Chalmers' Territory Expands—The L. H. Rose-Chalmers Co., recently established in San Francisco, Cal., to distribute the Chalmers, has opened on automobile row. The company has established sales and service branches in San Francisco, Oakland and Sacramento.

Motor Men in New Roles

Kelly Fisk Mgr.—D. B. Kelly has been appointed manager of the Louisville service station and repair shop of the Fisk Rubber Co., 941 Third Street.

Bragg Makes Change—F. L. Bragg, formerly retail sales manager of the Overland-Connecticut Co., has accepted a similar position with the J. H. Stuart Co., Burlington, Vt., Overland distributor.

Formigle Resigns—O. L. Formigle has severed his connections as assistant engineer of the Sheldon Axle & Spring Co., Wilkes-Barre, Pa., and will spend the summer at his home in Haddon Heights, N. J.

Rock Starter Inventor.—G. L. Rock, owner of the Jonesville Garage, Jonesville, Mich., has invented an automobile self starter and may interest local and Detroit people in promoting a company to manufacture the starter there or in Detroit.

Cadwell Sells Master Carbureter Interests—C. J. Cadwell has sold out his interests in the Master Carbureter Co. and is now connected with H. A. Miller of the Harry A. Miller Mfg. Co., Los Angeles, Cal., which will shortly bring out a new carbureter.

Canavan Sales Mgr.—J. J. Canavan, former member of the firm of Vance & Canavan, and controlling the agency for the Cartercar and Case lines in southern California and Arizona, has been appointed sales manager of the Pioneer Commercial Auto Co., Los Angeles, which has the southern California territory for the White.

Wiese Returns to Tire Business—J. F. Wiese of Los Angeles, Cal., has returned to the tire business. He has retired from the Winton branch and has formed a partnership with J. G. Boss, formerly in the tire business in Denver. Operating under the name of Boss & Wiese, a tire and repair business has been opened at 723 South Olive Street.

Donovan Baltimore Studebaker Mgr.—F. B. Donovan, Inc., has taken over the agency of the Studebaker in Baltimore. Mr. Donovan comes from Boston and is treasurer and general manager of the new company. A model service garage will be established with E. R. Maurer, formerly of the New York branch of the Studebaker agency, in charge.

Kalman Heads St. Paul Co.—The Twin City Motor Car Co., with quarters in St. Paul and temporarily at 719 Hennepin Avenue, Minneapolis, has elected the following officers: President, P. J. Kalman; vice-president and treasurer, J. P. Upham; secretary, W. G. Graves; sales manager, J. R. Histed; manager wholesale department, W. P. Abbey. A new building is being erected at Harmon Place and Willow Street.

Corson Back in Business—H. E. Corson, who retired from the automobile business last October after fourteen years of it in Springfield, Mass., where he had organized an agency and handled Ford cars, has gone back into the field again. He has formed the Corson-Berry Co. to handle the Studebaker line there, with headquarters at Winchester Square, State and Sherman Streets. John Mullarky, Jr., for ten years with Mr. Corson, has charge of the service department, and W. I. Stearns, Jr., until recently manager of the Blue Ribbon Garage, is outside salesman.

Cowan Sales Mgr.—W. K. Cowan, pioneer automobile dealer of Los Angeles, has been appointed sales manager of the William R. Ruess Co., distributor for the Mitchell and Stearns-Knight lines throughout southern California, Arizona and Nevada. Cowan took up the Waverley Electric in this territory in 1899. In 1902, when the first single cylinder Rambler car came out to the Pacific Coast, Cowan took on the agency and pioneered the automobile row there. Cowan continued to handle the Jeffery products until last fall, when he sold his interests and retired on account of ill health; but after a vacation he could not remain out of the industry and accepted the appointment at the head of the Ruess organization, succeeding J. H. McDuffie, who is now sales manager for the new Willys-Knight.

Dealer

Auto Parts to Enlarge—The Auto Parts Co. of Chicago, Ill., will enlarge both its radiator and top departments.

To Mfr. Pistons—E. W. Wridgway will manufacture the Zephyr pistons for automobiles under the name of the Wridgway Co., Wilkes-Barre, Pa.

Chicago Cole to Build—The Cole Motor Car Co., 2326 Indiana Avenue, Chicago, will erect a three-story service building, 50 by 161 ft., to cost $40,000.

Iowa Supply Co. Adds—The Iowa Auto & Supply Co., Des Moines, Iowa, will build a $10,000 addition to its plant. One floor of space of 9000 sq. ft. will be provided.

VOL. XXXIII NEW YORK—THURSDAY, JULY 29, 1915—CHICAGO No. 5

The AUTOMOBILE

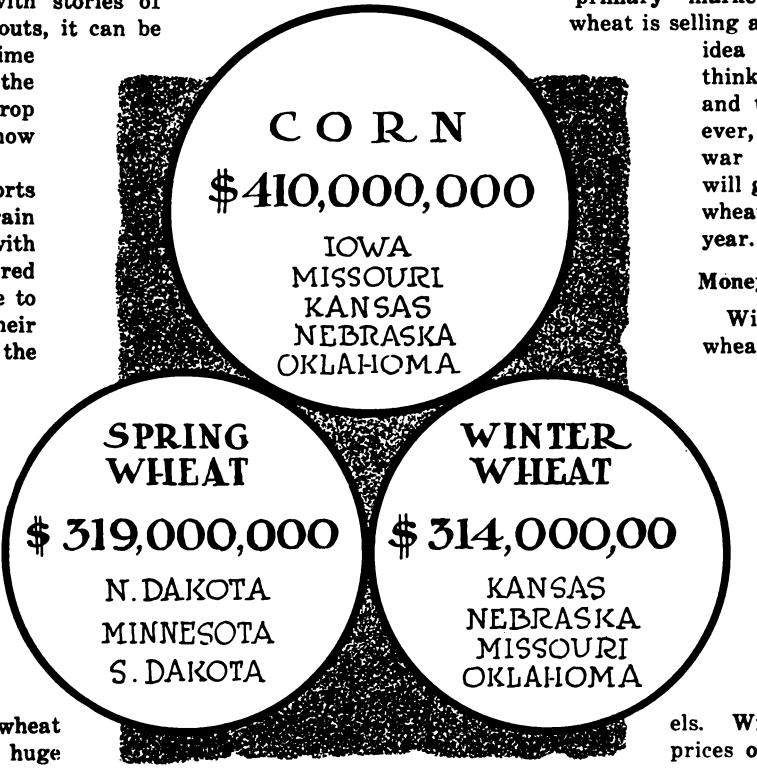
$1,058,000,000 from Crops in Valley West of Mississippi

KANSAS CITY, MO., July 21—Corn, spring wheat, and winter wheat, are the big three factors in determining the automobile buying possibility of the great agricultural plains west of the Mississippi, from Texas to the Northern boundary, and embracing Missouri, Kansas, Oklahoma, Nebraska, Minnesota and North and South Dakota.

From these States alone conservative estimates place the crop value for this year at $1,058,000,000, this total embracing only, at a sane market value, corn, spring wheat, and winter wheat.

As the automobile buying possibilities of these States are so largely dominated by the farmer, the crop value can be taken as a fair criterion of what automobile sales will be during 1916, and in spite of the almost daily reports of rain in these States, attended with stories of flooded farm land and washouts, it can be emphatically stated at this time that there is no danger to the great ready-money wheat crop which the Central West is now harvesting.

For days the market reports have contained reports of rain and flood, and men familiar with market conditions have feared the farmers would be unable to get into the fields for their harvesting. But Kansas, the biggest of all the winter wheat States, is three-fourths through; Oklahoma has practically finished and harvesting is proceeding in Nebraska; Missouri has fared about the same as Kansas. Grain men on the Kansas City Board of Trade who study crop conditions as closely as the market quotations themselves, are satisfied that the big four winter wheat States will have another huge crop, while the reports from the spring wheat States of the Northwest are equally encouraging. The rains in the Southwest will have some effect in shortening the crop, but nothing like what was feared if the rains kept up.



Good Wheat Prices

The Turkish forts still hold at this writing and if they should fall, it is believed by the grain men generally, that the price of wheat would be very little affected by the opening of the Dardanelles to Russian grain. There might come a quick drop, as was the case at the beginning of the attack, but they believe the market will go up again.

Cash wheat, of which there is very little now, is worth on the farm $1.10 to $1.40, depending on the distance from the primary market. For future delivery wheat is selling at $1.10, which gives a fair idea of what the wheat buyers think of the size of the crop and the war conditions. However, it is probable that if the war keeps going the farmers will get as good prices for their wheat this year as they got last year.

Money for Automobiles

With three-fourths of its wheat harvested, it is now estimated that Kansas will produce close to 135,000,000 bushels of wheat. This is 40 per cent larger than any previous crop except the one of last year when the State produced 180,000,000 bushels and sold it at its greatest price, from 90 cents to $1.40, depending on the time of sale. The average wheat crop in Kansas is 70,000,000 bushels. With the wheat at the war prices of last year, Kansas would

get from $130,000,000 to $190,000,000 for its wheat crop.

Imagine between $130,000,000 and $190,000,000 brought into a State largely from Europe, to pay the farmer for something that he has created. A ready-money crop with which the farmer may buy what he chooses!

70,000,000 Bushels in Nebraska

While Kansas is the greatest of the winter wheat States, Nebraska this year will produce 70,000,000 bushels on the July estimates. Missouri will have 37,000,000 bushels, a slight decrease over May estimates and Oklahoma will have 44,000,000 bushels. While Oklahoma will fall about 6,000,000 bushels below a normal wheat crop, Missouri will go as much over its normal crop. This means from the big four wheat States, 286,000,000 bushels of wheat this year. At the present quotation for September delivery this means $314,000,000 cash for this crop. If the war is on when the delivery of wheat begins in September, prices equal to last year's will be no surprise and they may go higher. At last year's war prices the crop of these four States will bring $400,000,000, all cash, which ought to be good news for the motor manufacturers with their increased output this year. While the rains have been heavy in the grain States in a season when the farmers needed dry periods for their work in the fields, the downpours offset the loss from the chinch bug which were doing great havoc.

Spring Wheat Reports

Reports from the spring wheat States of the Northwest are equally encouraging. The big three, North Dakota, Minnesota, and South Dakota, report good growth, and while the crop, of course, will not be harvested until some time after the winter wheat crop, there is every reason to look for a big crop, both on account of acreage, and the spring rains. The rains have not been so frequent in the western part of South and North Dakota. Nebraska has of late years become almost entirely a winter wheat State, but this year it will have the usual amount of spring wheat. The outlook in the spring wheat States based on the acreage is:

STATE	ESTIMATED ACREAGE	ESTIMATED BUSHELS
North Dakota	8,000,000	106,000,000
Minnesota	4,500,000	65,000,000
South Dakota	3,750,000	53,000,000
Nebraska	300,000	4,000,000

This makes a total of 228,000,000 bushels of spring wheat, worth at war prices $319,000,000. That gives in the spring and winter wheat States this year and fall $719,000,000 in cash from outside sources.

Corn Is Backward

The July indication for corn in the corn belt of the grain States indicate a good corn crop this year. The rains, while so frequent in many sections that they have prevented cultivation, have given the corn a fine growth and the weeds can be pretty well taken care of in the next two weeks. From the July reports of corn conditions these estimates can be made of the crop outlook for these States, the principal corn States:

STATE	1914 CROP, BUSHELS	NORMAL CROP, BUSHELS	ESTIMATE FOR 1915, BUSHELS
Iowa	389,000,000	400,000,000	306,000,000
Kansas	108,000,000	175,000,000	96,000,000
Missouri	158,000,000	200,000,000	183,000,000
Nebraska	175,000,000	200,000,000	156,000,000
Oklahoma	50,000,000	100,000,000	80,000,000

This is a total of 821,000,000 bushels of corn in the five big corn States west of the Mississippi River, a crop that will sell from 50 to 75 cents a bushel, bringing from $410,000,000 to $615,000,000 if sold for shipment. However, these States feed their corn and sell their livestock so that the return is much greater. Wars do not generally affect the price of corn except in that it affects the price of meat.

The other field crops of the West are doing well. The alfalfa of Kansas alone this year will make a $15,000,000 crop. The value of these crops will mean that the farmer will have less need of his wheat money in taking care of actual living expenses. The grain States of the Mississippi Valley may all be judged from the condition of Kansas, which raised nearly half of the winter wheat in the western States.

Automobile Increase 442 Per Cent

It is of unusual interest to note the way in which motor car sales have increased in Kansas, which represents probably more than any other State the farmer himself. Since 1910 the increase of automobiles in the State has been 442 per cent. The increase for the whole United States has been in the same period 240 per cent. Of the States that have 20,000 motor cars in use, Kansas's percentage of increase has been exceeded by only one State, Minnesota, great in spring wheat and dairy products.

This increase by years from 1910 shows:

March, 1910	9,301	Gain
March, 1911	14,456	5,115
March, 1912	18,625	4,139
March, 1913	24,794	6,169
Jan. 1, 1914	34,945	10,151
Jan. 1, 1915	50,454	15,509

Cars in Kansas

The survey of the automobile users in Kansas serves as a lesson in what the farmer means to the automobile industry. Kansas has only one large city, Kansas City, Kan., and that city has less than 100,000 population. The other cities of the States are county seat towns, mostly running from 1000 to 5000 population. There are two or three exceptions, Topeka, Leavenworth, Wichita, Atchison and Hutchinson, but with the exception of Topeka all represent the farmer and all live from the farmer's products. A survey of the industry in the State shows that where the towns are smallest the number of persons per car is likewise smallest.

Twenty-two Persons per Car

Pawnee county in the central part of the State, where wheat rules, has 547 cars with an average of only fourteen persons to the car. Almost as good a showing is made in Edwards and Lincoln counties with an average of fifteen persons per car each. Such thickly settled counties as Barton and Reno show averages of twenty-two persons per car each. And in Barton county are several small towns and in Reno the town of Hutchinson with a population of 16,000.

75,000 Cars Possible

It is impossible to give the figures of every county in the State with the number of cars and the number of persons per car, also showing the remarkable way in which the average of persons per car is going down. The moral, of course, is that where there are twenty-two persons per car in a county filled up with average sized farms, some small towns and a city the size of Hutchinson, every other county in the State, barring possibly the counties with towns of more than 50,000, can be made to have as low a percentage. This means that Kansas with a population in 1914 of 1,672,106 could be showing the use of 75,000 automobiles without difficulty and if the lowest present percentage of any county in Kansas were reached over the entire State, the number of cars in use would be 111,474, more than twice as many as are in use at present. And is there any reason why a rich Kansas county should not have as few persons per car as a county that is poorer in wealth which is the case in a third of the 105 counties of the State?

New Four Heads Jeffery Production List

Is Larger, More Powerful and Better Engineering Than Previous Model and Sells at Far Lower Price—Two Sixes Practically Unchanged Though Prices Are Lower

INCREASED production and clever engineering are factors in the success of the Thomas B. Jeffery Co., Kenosha, Wis., in bringing a car listing at $1,550 in 1914 down to the $1,000 class in price while at the same time making its details of construction and general appearance far in advance of the earlier, more expensive car.

The answer of the Jeffery company, Kenosha, Wis. to the appeal of the buyers, is a standard four-cylinder, seven-passenger car at $1,035 or the same car without extra tonneau seats at $1,000. This car uses the same motor as the $1,275 four of 1915, but the refinements and changes made in the chassis and the substitution of an entirely new body make it stand out as a new vehicle built to the demands of the American purchaser and sold at a price within his means.

Jeffery's new four will head the factory production list but as trailer there is the Jeffery six at $1,350, which in the 1915 season was called the Chesterfield and listed at $1,650. The six has been changed little, so little in fact that the maker has laid no stress on the refinements, making more striking the importance of the four.

Larger Than Previous Four

While the car has been reduced $275, it is larger than the previous four, it is more powerful and a better hill climber, shows better fuel economy, is easier to handle and on the whole is a better vehicle and will be heralded as such by those making a comparative design study. In general it has a 3¾ by 5¼ block motor, disk clutch, three-speed gearset, and semi-floating axle. The wheelbase is 116 in. and tires 34 by 4.

Three varieties of changes have been made, those resulting in better performance, greater stability and better appearance.

Under the first head comes the motor changes, which outlined briefly are: a change from separate gearset to unit power plant construction, alterations in carburetion, ignition, and the adoption of a new Bijur two-unit cranking and lighting system. The camshaft has been redesigned, the crankcase changed in material and appearance and the cooling system has been gone over.

Also under performance changes comes the new clutch which is fitted with a brake, longer rear springs, a new gearset of the three-speed type instead of four and behind it the emergency brake. The whole driving system is new from flywheel to axle.

The changes tending to greater stability of the mechanism are seen in the use of different metals in various places. The crankcase, for example is of cast iron instead of aluminum. The weight of the car has been reduced and there has beer a re-proportioning of sprung to unsprung weight.

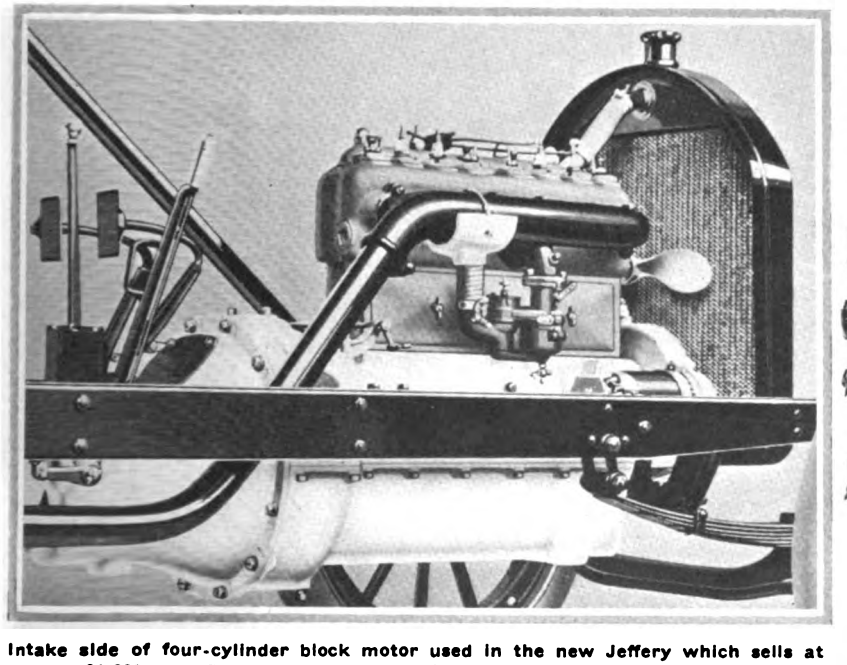
The appearance changes are apparent. The body is a cleverly laid out one of new lines, with new equipment and much roomier than the older one.

In the motor there are not so many changes as elsewhere but even though few they are quite important.

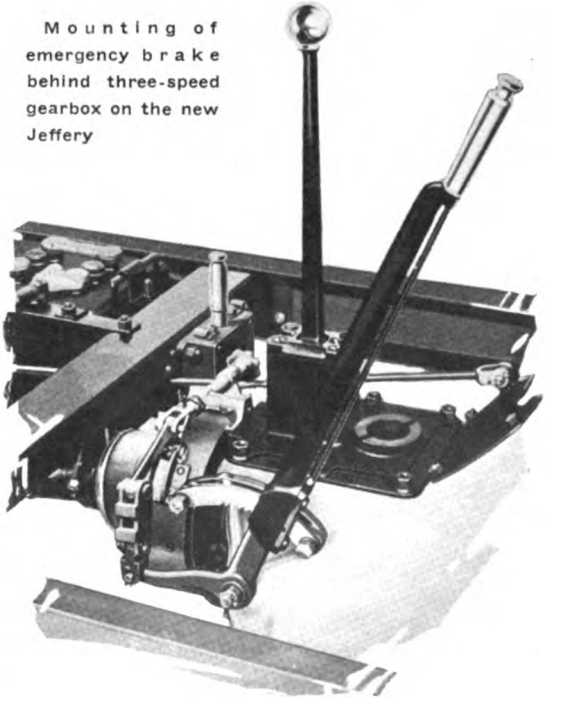
The cylinder dimensions, 3¾ to 5¼, are the same as before but the power, especially for hard pulling such as hill-climbing work, has been increased by using a new camshaft with different-shaped cams and these placed so as to change the valve timing as follows:

	1916	1915
Inlet opens	12 degrees late	18 degrees late
Inlet closes	46 degrees late	46 degrees late
Exhaust opens	46 degrees early	47 degrees early
Exhaust closes	12 degrees late	15 degrees late

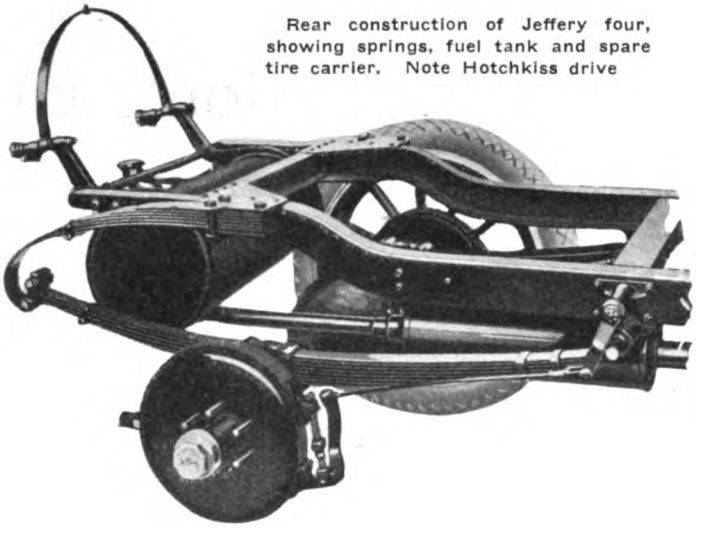
With the change in camshaft design the push rods now are of the mushroom type instead of roller as previously. All



Intake side of four-cylinder block motor used in the new Jeffery which sells at $1,000 as a five-passenger and with extra tonneau seats at $1,035



Mounting of emergency brake behind three-speed gearbox on the new Jeffery



Rear construction of Jeffery four, showing springs, fuel tank and spare tire carrier. Note Hotchkiss drive

of this has been done to get a better effective valve opening and to give more snap to the engine on hill work and rough going.

A power addition also has been obtained, and with it a slight increase in fuel economy, by joining the inlet and exhaust manifolds; that is, having them become integral at one point. This means that the heat from the exhaust manifold is imparted to the inlet and hence better vaporization is obtained. The carbureter, which is on the right side, is new, being a type K Stromberg, and mounted in a better position. It is slightly higher and feeds through cored passages which have been smoothed and straightened out so as to increase the speed of the ingoing gases. The carbureter now is fed from a Carter fuel tank by gravity instead of by pressure.

The exhaust manifold now attaches to the exhaust pipe without flange and bolts, the joint being a pinch fit. This makes a better joint, a simpler one and one which will not cause leakage so readily.

On the left side of the motor a change is apparent. The Folberth pump which used to be driven from the water-pump shaft has been removed and now is on top of No. 4 cylinder. The magneto also driven by the water pump shaft now is a Bosch NU4 instead of a Bosch duplex and, by the way, this is the only source of ignition. The removal of the tire pump has allowed of the magneto being placed a little more forward and in a more accessible position.

The valves are still of Rich tungsten steel but the springs have fewer convolutions and have lighter tension so as to work better in conjunction with the mushroom followers. Now that the lift is not so abrupt, these changes give better valve opening and closing and hence better performance at the higher speeds.

New Aluminum Fan

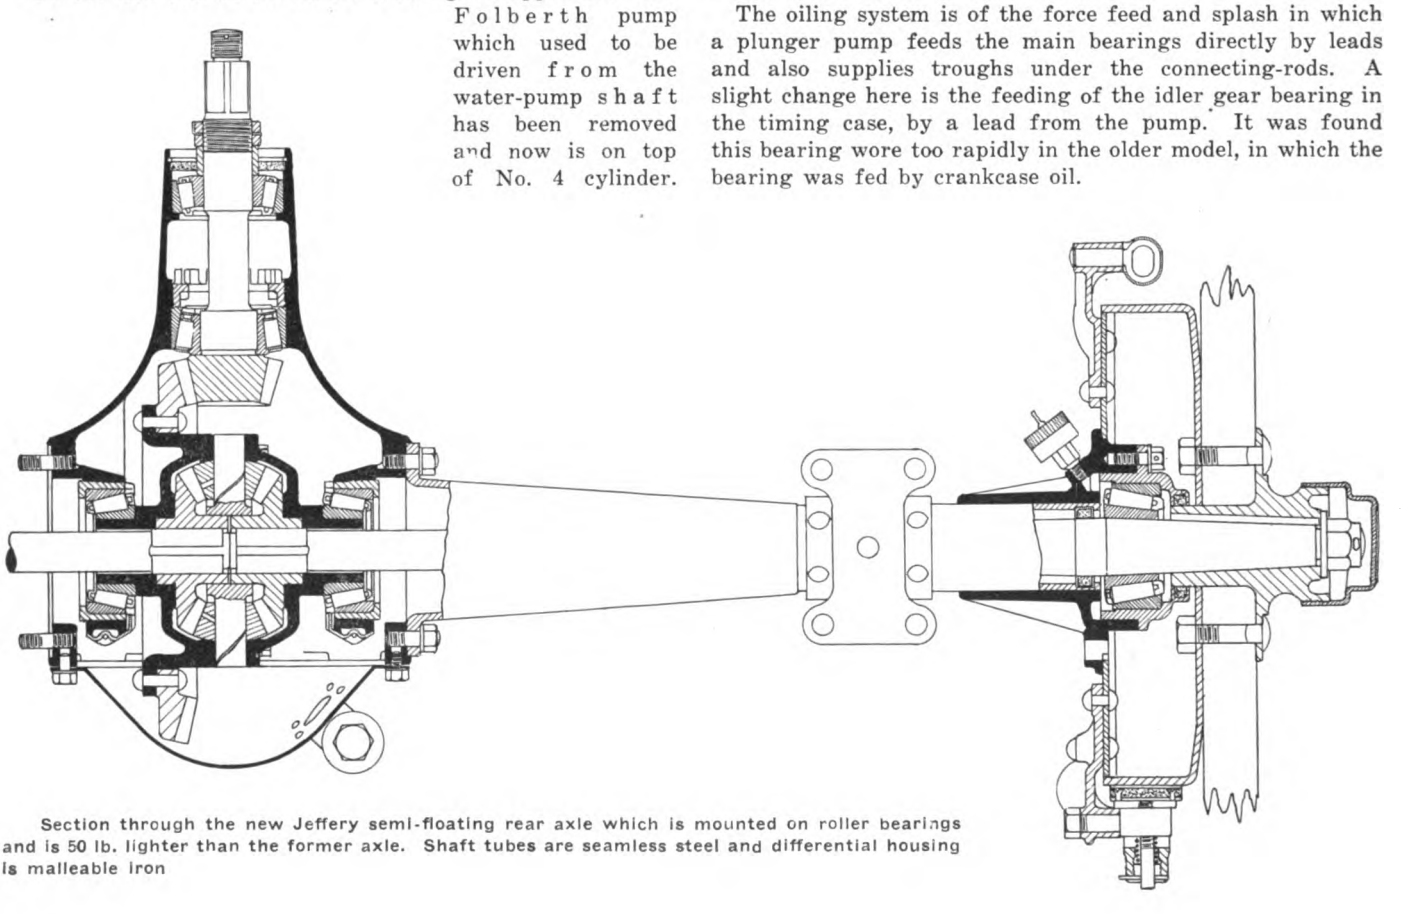
In the cooling system there is a new two-blade, aeroplane-type fan made of aluminum instead of the former pressed-steel, five-blade type. This change has saved a little weight and the new fan gives a greater air draught and working in conjunction with a new radiator gives better all-round cooling efficiency. The radiator is a new tubular type of 8 gal. capacity instead of 9, it is 25 lb. lighter in weight when filled and has greater cooling area. This radiator is made by the National Can Co. while the former one was made in the Jeffery shops.

The crankcase upper half now is of cast iron instead of aluminum the change having been made to save money and make a more rigid construction. The crankcase cover still is of aluminum. Also, there is a new form of bell housing to accommodate the clutch and gearset which was not the case before.

Few Motor Changes

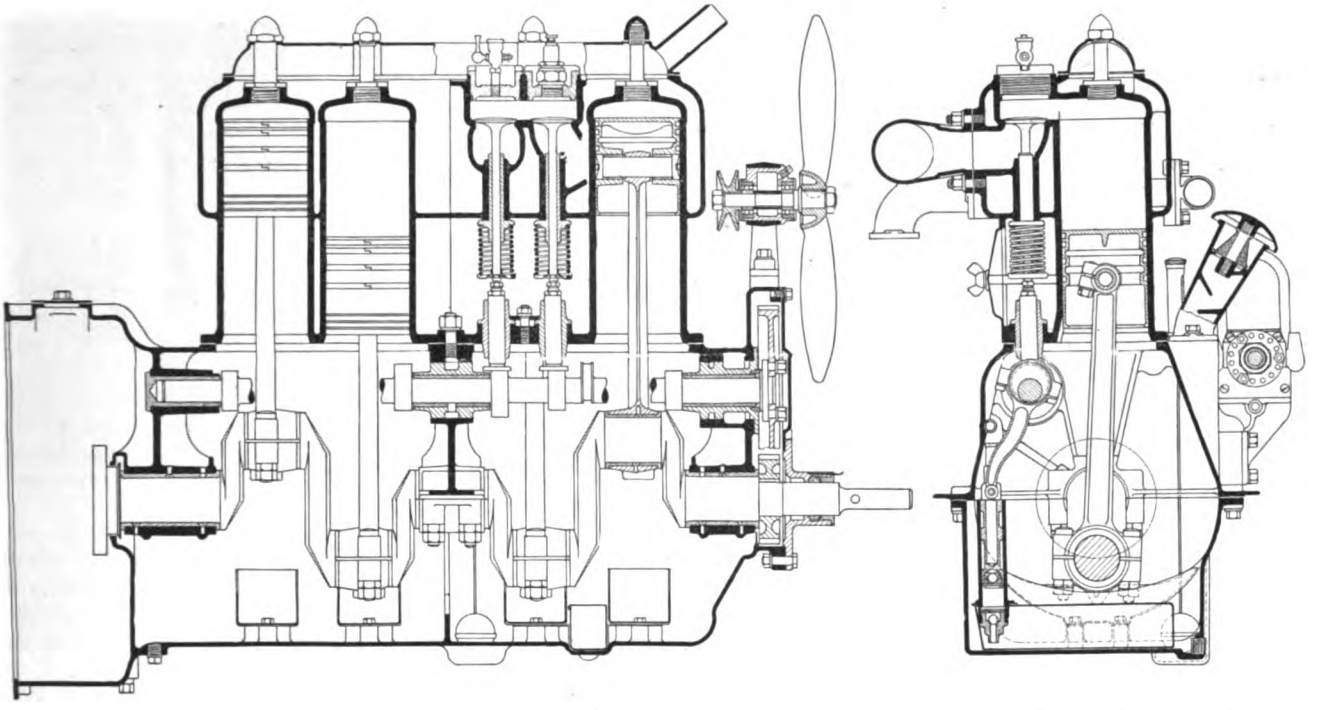
In the interior, the motor has not been changed much. The crankshaft is a 2-in. with three bearings of the following sizes: front, 3¼, center, 3¼, end, 4½. The pistons and rods remain the same and show nothing out of the ordinary. The piston weight is 3 lb. 9½ oz., including pin and rings, the piston length, 4-38 in. and the pin diameter, 15-16 in. The rings are a step-joint type. The connecting-rods weigh 4 lb. 10 oz. and are 12¼ in. center to center.

The oiling system is of the force feed and splash in which a plunger pump feeds the main bearings directly by leads and also supplies troughs under the connecting-rods. A slight change here is the feeding of the idler gear bearing in the timing case, by a lead from the pump. It was found this bearing wore too rapidly in the older model, in which the bearing was fed by crankcase oil.



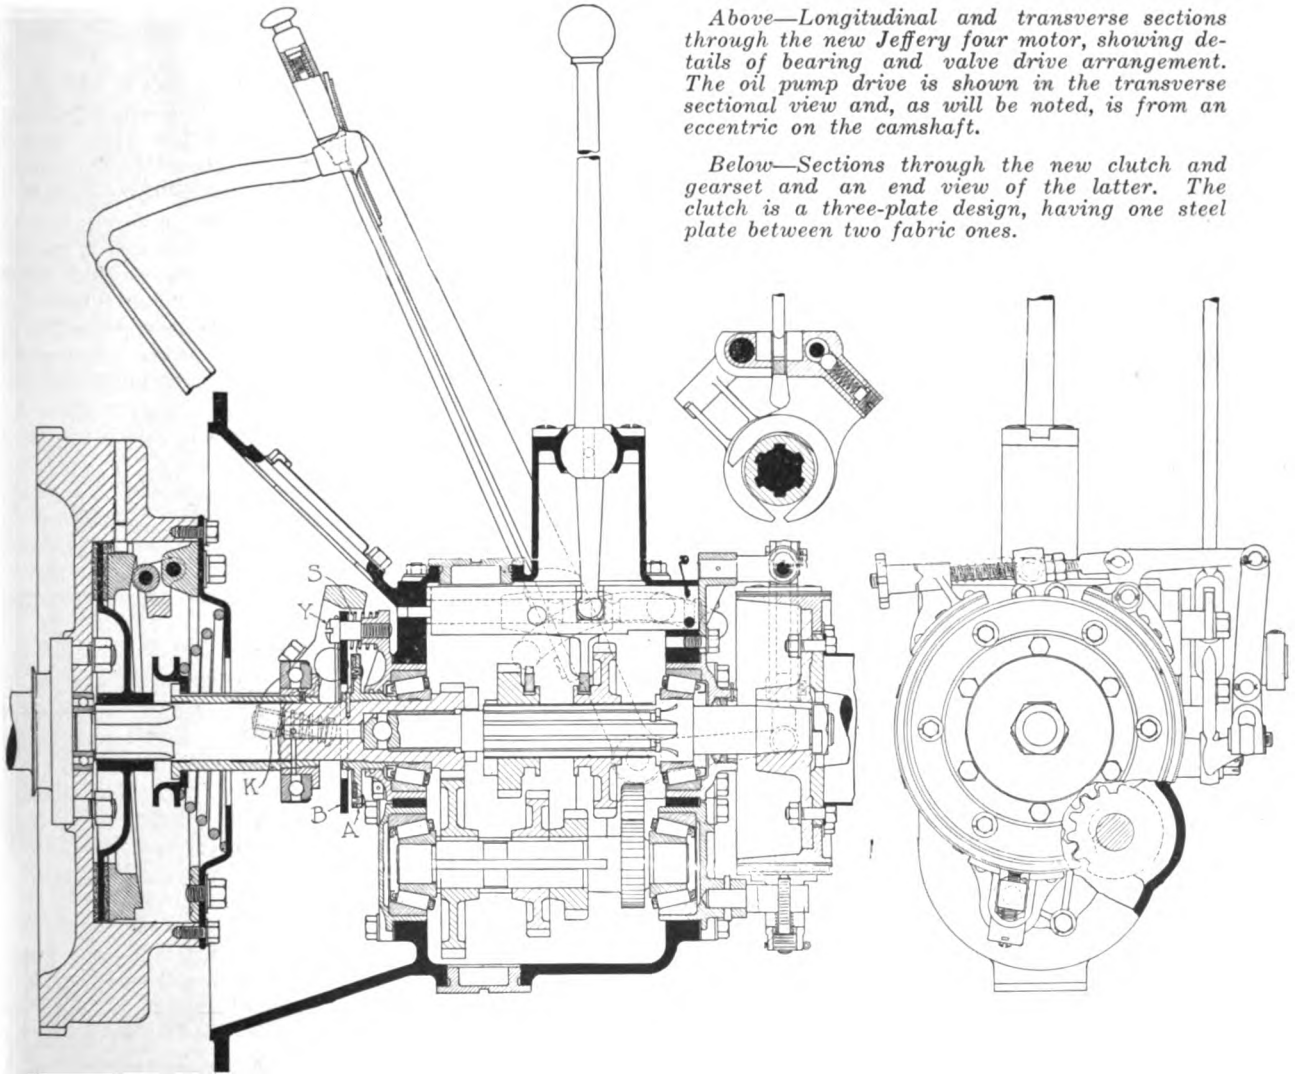
Section through the new Jeffery semi-floating rear axle which is mounted on roller bearings and is 50 lb. lighter than the former axle. Shaft tubes are seamless steel and differential housing is malleable iron

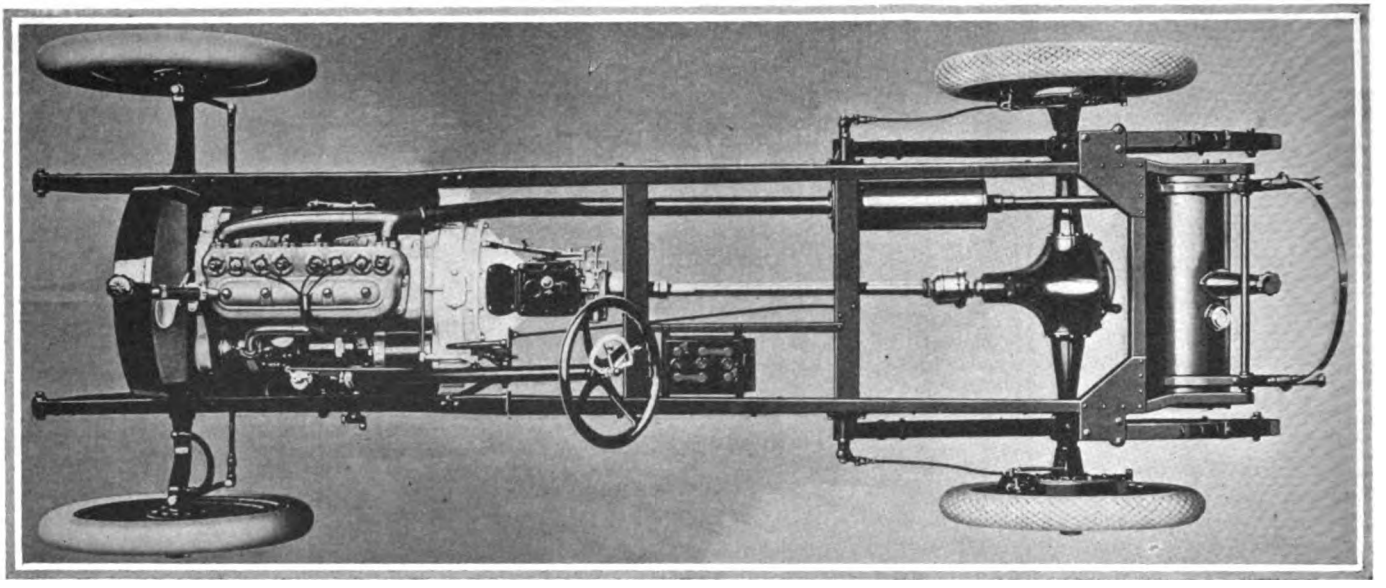
Features of the New Jeffery Four



Above—Longitudinal and transverse sections through the new Jeffery four motor, showing details of bearing and valve drive arrangement. The oil pump drive is shown in the transverse sectional view and, as will be noted, is from an eccentric on the camshaft.

Below—Sections through the new clutch and gearset and an end view of the latter. The clutch is a three-plate design, having one steel plate between two fabric ones.



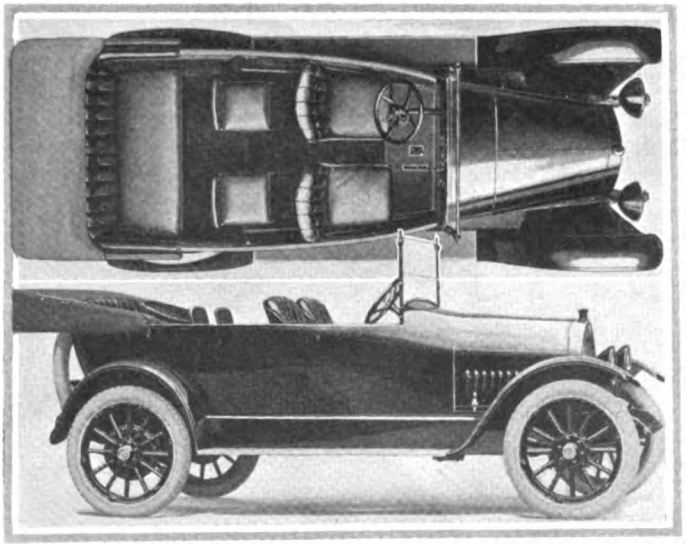


Plan view of the new Jeffery four chassis, showing strong, compact layout of the various units

In changing from the flywheel type of cranking and lighting system to the two-unit Bijur there has been made a saving in weight and power. The new system uses a U. S. L. 6-80 battery instead of a 6-12 volt 100, the smaller battery doing the necessary work in causing the starting motor to turn the engine over at 160 r.p.m. The old motor was turned at 250 r.p.m. which Jeffery engineers thought was too much, requiring too much current and showing no better results than the present system. The former starting system weighed 250 lb. including battery and this one weighs only 86 lb. with battery.

Operation of Bijur System

In the Jeffery application of the Bijur system the generator is driven from the timing gears on the right side and operates at one and one-half times motor speed. The regulation is inherent and it starts charging the battery at about 8 m.p.h. The cranking motor is on the left side and meshes with the flywheel by means of a mechanically shifted pinion. Pressure on the starting pedal causes the pinion to slide into mesh with the flywheel and at the same time connection is made with the battery so current flows through the starting motor. The reduction of cranking motor to engine is 11.6 to 1.



Plan and elevation of the four-cylinder, seven-passenger Jeffery touring car for 1916

With all of these changes, the Jeffery motor shows a higher revolution per minute than the former one and more power at that speed. On the test block it gives about 40 hp. at 1900 r.p.m. and it is stated it will run over that figure without reaching the peak of the curve.

The influencing factor in changing from separate gearset to unit power plant has been ease of assembly but there are others such as accessibility and cost reduction which have played a part.

The new clutch is a three-plate dry-disk with one steel plate and two faced with fabric. In connection with this clutch, which supplants the cone of last year, is a clutch brake of simple construction. As shown in the illustration herewith the main shaft has threaded to it the plate *B* which has fabric facing on a portion of its surface. Behind this plate is another spring backed plate *A* which is mounted so that it can slide freely on the bolts *Y*, of which there are three, spaced 120 deg. apart. In the clutch throwout collar *R* are two pins *K*. When the clutch is dis-engaged the throwout collar moves backward as shown by the arrow and after traveling a certain distance the pins *K* touch the plate *A* causing it to move forward and rub against plate *B* thus stopping the main shaft from rotating, and so stopping the clutch from spinning.

The clutch as a whole, gives better throttling performance than the former cone type and makes a better installation now that a unit power plant is used and the flywheel type generator removed. A feature of this clutch, which will appeal to the owner is that it may be adjusted for slipping, in 2 min.

New Three-Speed Gearset

Behind the clutch is a new three-speed gearset made in the Jeffery plant. This differs from the former one in that it has the main shaft below the shifter instead of beside it. This makes a cleaner installation. It is much lighter than the former four-speed and is fitted with tapered-roller bearings instead of ball. The gears are ⅝ face nickel-steel, and the shift now is by center lever in a ball joint instead of by H-slot.

In the fitting of this new gearset the Jeffery company has applied a gearset brake which is adjustable in a few minutes and is accessible by lifting the front floor boards. This brake, because of its effectiveness is used as the emergency and is operated by the usual center lever. It uses fabric facing for the band which is 2½ in. wide. The drum is 7 in. in diameter.

Continuing in the drive there is a hollow propeller shaft, of 1½ in. diameter instead of a solid shaft, 1⅜, with two Kinsley-Bennett joints instead of joints of another make, and a new type of semi-floating rear axle instead of a floating. This axle is mounted on roller bearings instead of ball and is 50 lb. lighter than the former axle, thus reducing the unsprung weight. The shaft tubes are seamless steel and the differential housing, malleable iron. The gears within are spiral-bevel instead of straight bevel and the motor to wheel ratios are as follows: first speed, 13.49 to 1, second, 7.55 to 1, third, 4.15 to 1 and reverse, 17.97 to 1. One set of brakes are used in the axle and these act as the service set.

Drive Taken Through Springs

The propulsion members used in the 1915 car have been discarded and the drive now is taken through the rear springs, to simplify construction and save weight. To do this the shackle bolts have been increased from ⅞ to 1 in. in diameter and the main spring leaves made of alloy steel. The rear springs have been lengthened to 54 in.

In the controls there is a Warner, Muncie, steering post instead of that used on the 1915 car, and as previously mentioned, a new gearshift lever. The light and ignition controls have been simplified and rearranged on a new cowl board.

The body is an entirely new seven-passenger but is sold without the auxiliary seats thus making it a five-passenger. The body lines, like the Chesterfield of 1915, are conservative streamline and the unit is much better than the former one, has more taper in front and better curves on the sides. The front seats are separated and have a reasonably wide aisle between them, this being new for this car.

New One-Man Top

In the equipment there is a new one-man top instead of the regular type, a Carter fuel feed tank which converts pressure to gravity, instead of straight pressure with the tank at the rear, a circular-section tank instead of a square one and a new type of Rand windshield. Tires remain the same, 34 by 4, but they are mounted on Stanweld rims instead of those employed previously. In the instruments there is an oil gage which is new and a combination terminal board and fuse block in front of the cowl. With this fuse replacement is a matter of a few seconds even at night for a spare fuse is in the box and it may be replaced easily. The dash lights have been done away with and Solar dimmers placed in the headlights.

—

New Wollaston Valve-in-Head Motor

An overhead valve motor has been designed by the Wollaston Foundry Co., of Norfolk Downs, Quincy, Mass., which is in the business of making iron castings and doing electric welding. The motor, which is illustrated herewith, has an overhead camshaft running in a separate housing submerged in oil. Upon this shaft are four integral cams which operate the eight valves directly without the use of rocker arms. The overhead valves themselves are set in a removable head which has an inspection cover on either side allowing for accessible valve adjustments.

The camshaft is driven by silent chain on one motor and by vertical shaft and spiral gears on another, both of which are experimental jobs. Both systems work out satisfactorily. Oiling is by force feed with the lubricant drawn from an aluminum oil sump by gear pump which forces the oil to the camshaft bearings, through the main bearings to the crankshaft and to the lower connecting-rod bearings. The oil sump is removable and the connecting-rods and pistons can be inspected or taken out through the bottom of the crankcase without disturbing any other part of the motor.

These motors are adapted to automobile use as is shown by the fittings of standard bell housings bolted to the rear end of the crankcase. The water connections are arranged to be adjusted to any angle and to suit any radiator connection. The motors illustrated are fitted with a Detroit Gear & Machine Co. gearset and clutch.

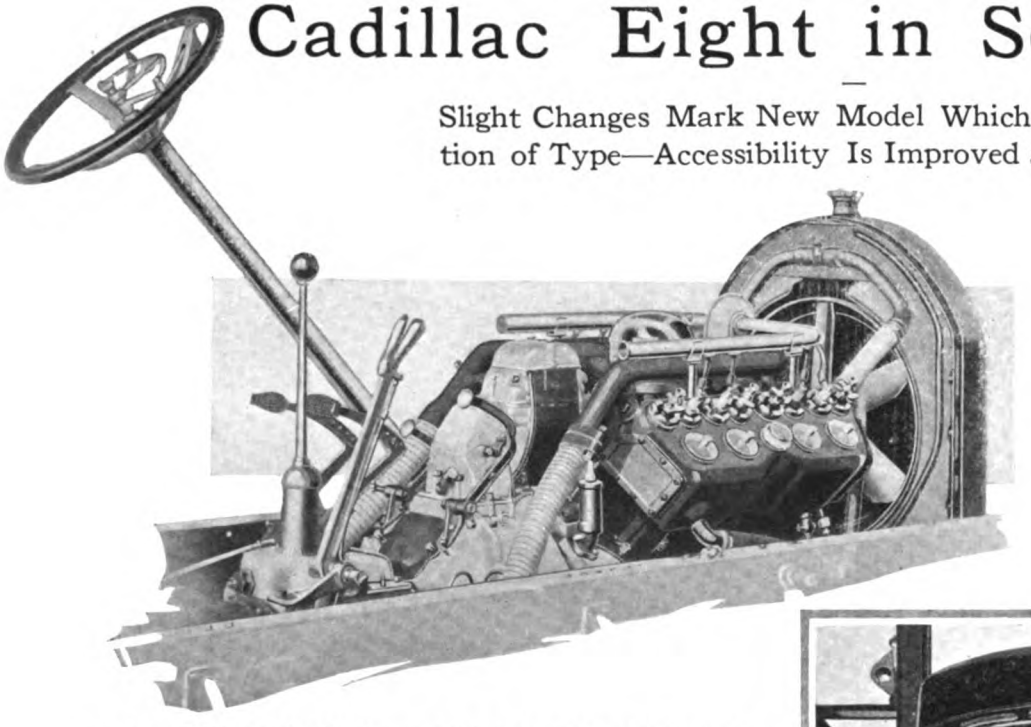
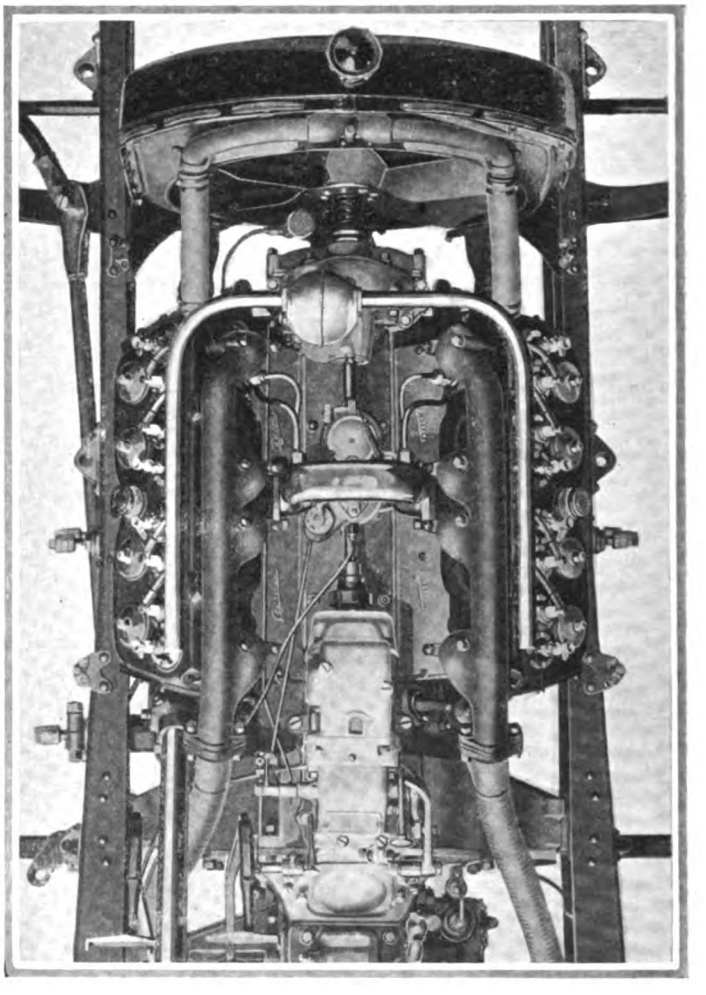
Cadillac Eight in Second Year

Slight Changes Mark New Model Which Proves Satisfaction of Type—Accessibility Is Improved and Body Larger



Left—Fore part of 1916 Cadillac chassis, with the eight-cylinder motor installed. This view gives a good idea of the new style ignition leads which can be detached as a complete unit without loosening any nuts

Below—Plan view of the eight-cylinder motor in the 1916 Cadillac, showing the accessibility of the tappets, a feature of the refinements for the coming season. Note the mounting of the tire pump beside the gearbox



WHEN an absolutely new thing, like the eight-cylinder motor was a year ago, is first put upon a manufacturing basis, it is usual to find that the first year of real production will show up some weaknesses. With a car which was as great a change from previous models as was the eight-cylinder Cadillac it would be reasonable to expect some points of imperfection in the first model, however careful the experimental work, so the fact that the Cadillac eight is to enter its second season practically unchanged is really noteworthy. It means that the features which seemed good to the skilled men who tried out the experimental cars, have shown up well in the hands of many thousands of users who are a long way from being experts.

Few Changes Necessary

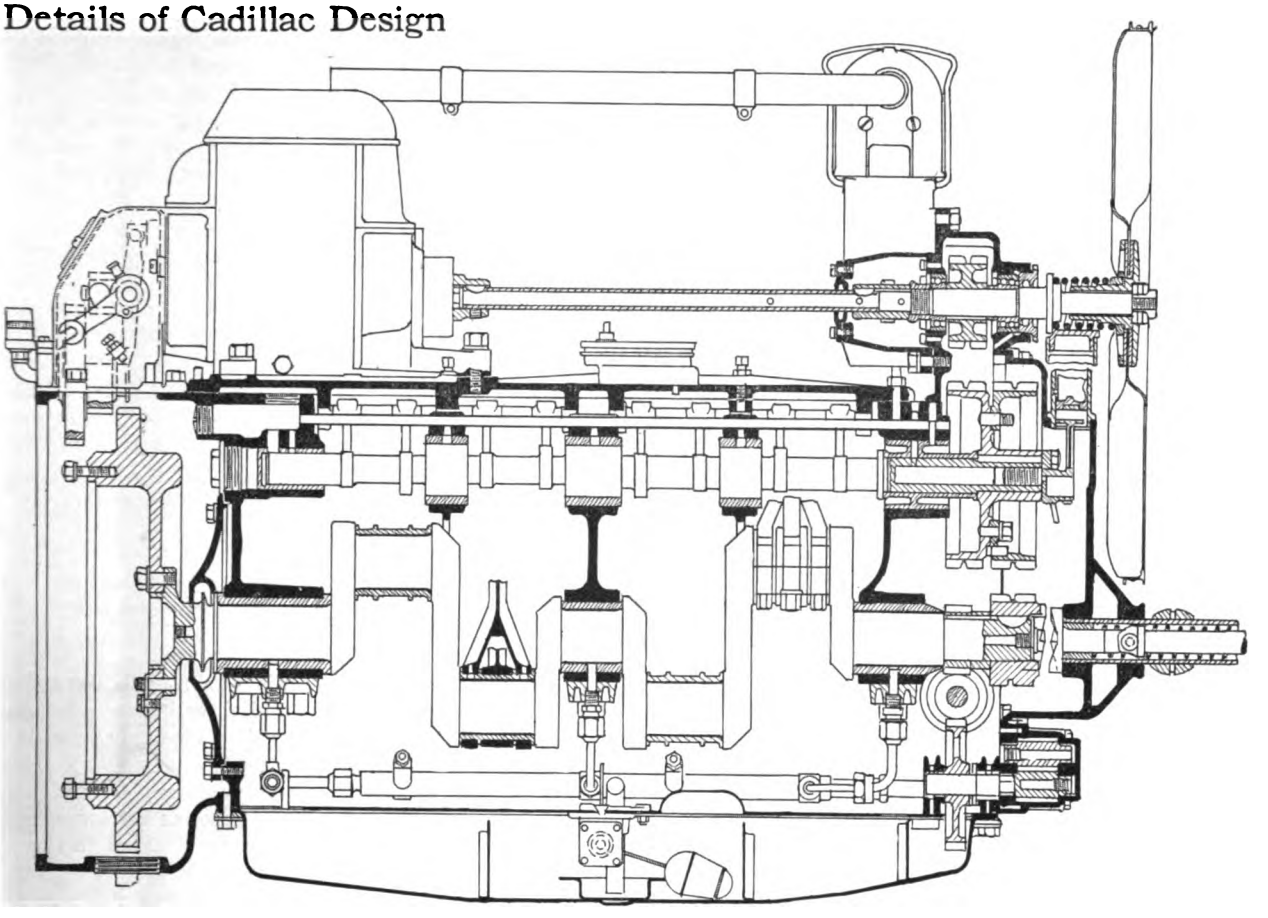
In a factory producing many cars, however good these cars may be, there are always some troubles, for it may be doubted if there is any machine in the world that is incapable of improvement. With new machines the troubles are usually more frequent and serious than with old ones and no doubt even the Cadillac has not been entirely free from complaints. The important thing is that no trouble has turned up which is due to any feature of the car, since had this happened changes would have been made. Thus one may say that the entrance into a second season with every single important feature of the chassis unaltered indicates a really remarkable foresight in planning both the design and manufacture of the car.

Price Increased $105

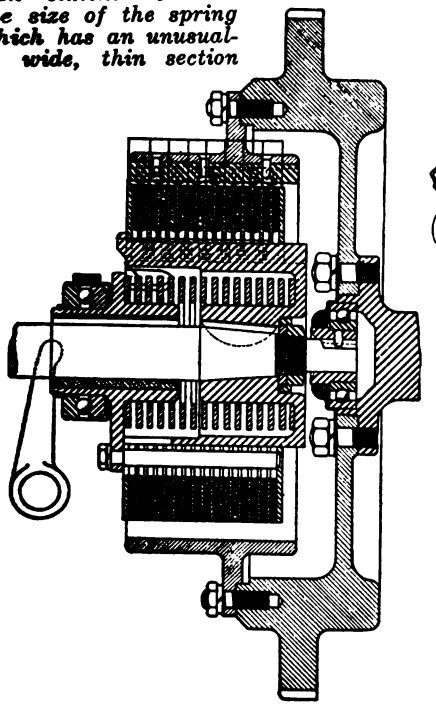
The Type 53 Cadillac will cost a little more than the original model, $2,080 as against $1,975. Five-passenger salon and seven-passenger bodies will be made for the coming season. Anent the price increase the company announces that the original price was fixed at a time when the production cost was not known, as the car was announced some considerable time before the plant was re-equipped to turn the eight. In accordance with the established practice of the company, no cut in the quality of the material has been considered and it is thus found necessary to raise the price in order that the margin of profit may be sufficient to give a reasonable, business return to the stockholders.

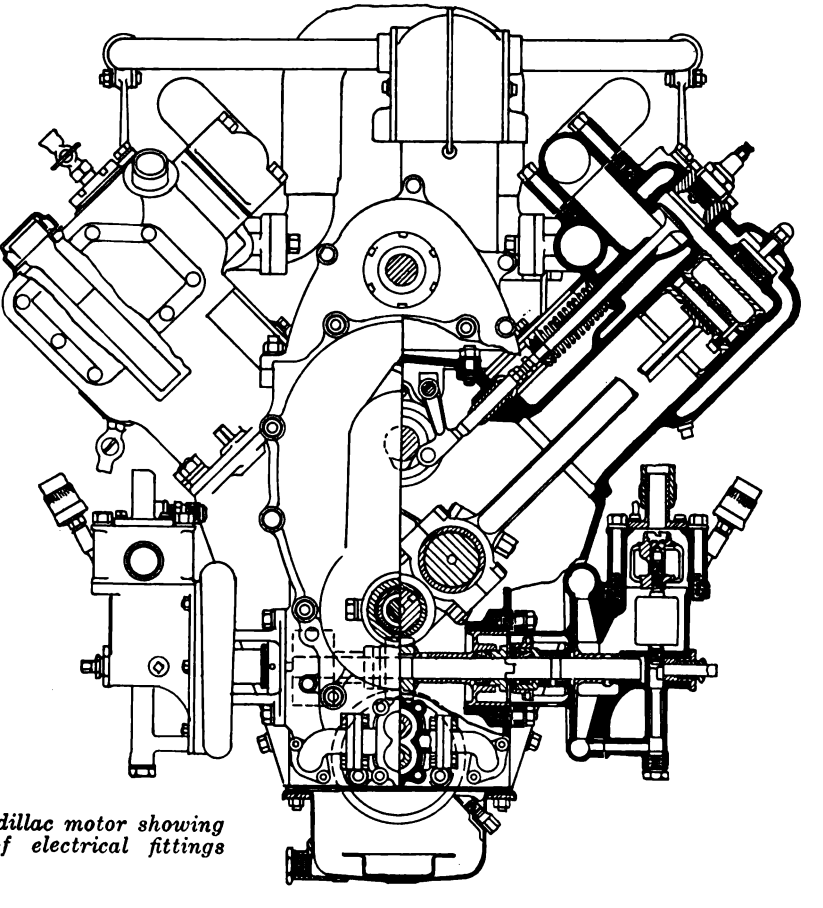
The change in design that is most noticeable is directed toward the improvement of the valve accessibility. On the old model it was perfectly possible to set a valve tappet, but the job was a little awkward to an unskilled mechanic. To make the task easier, the generator-and-starting-motor unit has been moved back a few inches, and the ignition breaker and distributer brought to the extreme front of the motor thus clearing the space between the cylinders of everything except the carbureter, because the tire pump has been removed from the motor altogether and is now located on the side of the gearbox.

Details of Cadillac Design

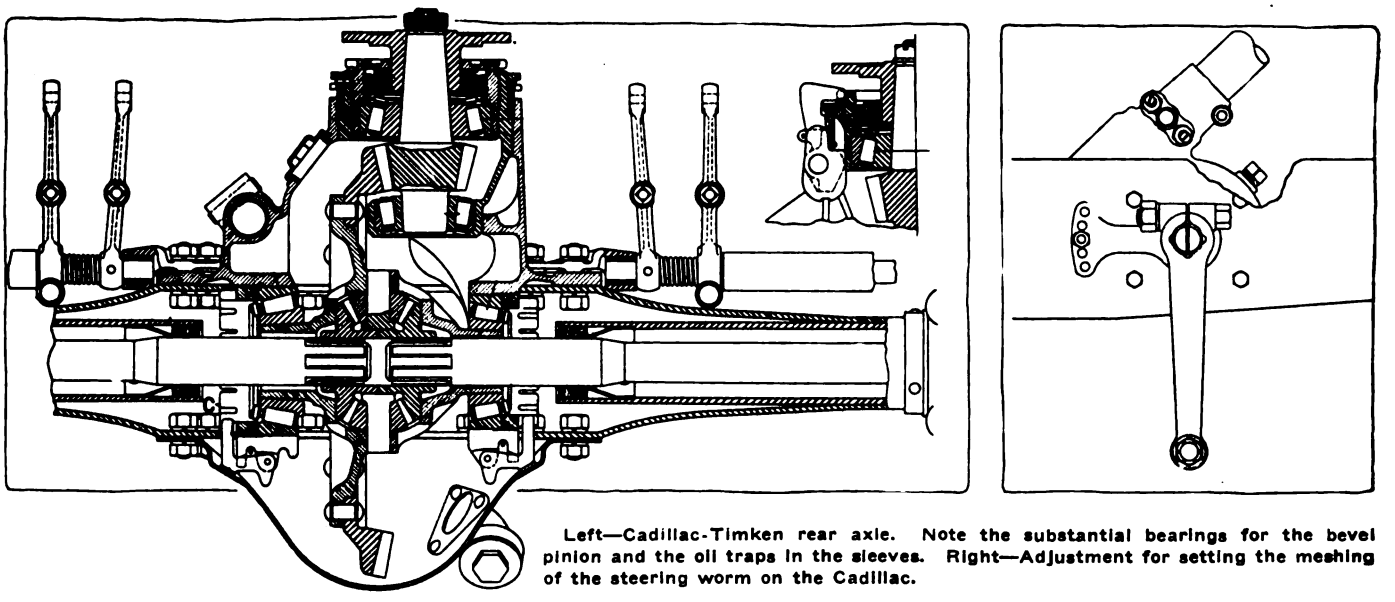


The sixteen-plate dry disk clutch. Observe the size of the spring which has an unusually wide, thin section





Sections of 1916 Cadillac motor showing changed position of electrical fittings



Left—Cadillac-Timken rear axle. Note the substantial bearings for the bevel pinion and the oil traps in the sleeves. Right—Adjustment for setting the meshing of the steering worm on the Cadillac.

Also the exhaust manifolds have been raised and separated further by lengthening and curving the four branches on each which connect to the cylinder outlets. It is now possible to grind the valves and adjust them without removing anything except the plates which inclose them. Still, to render it less troublesome to remove the carbureter, the ignition wires have been redisposed so that they branch right and left at the distributer, instead of being taken to the old cross conduit on top of the intake manifold. The conduits are held in clips, and the aluminum casing which incloses the distributer is also secured by a spring wire hasp, so that when the ends of the leads are detached from the spark plugs, the whole high-tension system can be removed completely by simply pulling it off.

Second Speed Lowered

In the gearbox the only change is a slight lowering of the middle gear ratio, so as to give still better pulling power on the rare occasions when the lower ratio is needed.

The new location for the tire pump on the left side of the gearbox makes for convenience, as it is no longer necessary to raise the hood in order to utilize the pump. It is connected by means of a small sliding gear as before, and there is a small brass button with a screwdriver slot in it brought through a hole in, and flush with, the floor board of the driver's compartment. The air line is taken to the tool box where the flexible tube would be stored, so that the process of connecting up is rendered quick and trouble free. The idea in using a screwdriver to turn the gear shift button of the pump is that this tool always is to be found in the door pocket, and it is desirable not to add another pedal or to have any additional projection through the boards.

Another change which will be appreciated by tall adults, is that the adjustable clutch and brake pedals have been moved two inches forward, thus increasing the possible range of adjustment; and another thing which makes for the driver's comfort is the new location of the horn button in the center of the steering wheel.

Body Appears Much Larger

Using slightly higher hood and providing higher sides to the body has increased the apparent size of the open cars quite considerably. Actually there is a good deal more room inside, but this is obtained mainly by increased width. The rear seat is wide enough for three passengers of 200-lb. caliber and the folding seats are not uncomfortable for anyone of normal or even a little over normal size. For upholstery an excellent quality of hand buffed leather is being used. Despite the greater accommodation it is said that the weight has been only slightly increased.

More Power Available

What might be called a settling down in the manufacturing of the eight has resulted in a slightly higher average motor power and the engines coming through lately have been giving a very good account of themselves. One little addition to the carbureter no doubt is partly responsible, as it is also for some slight improvement in the gasoline consumption. This consists of a small shutter which is attached to the throttle operating rod and varies the size of the air intake in proportion to the throttle position, the control being quite separate from the usual air valve, which is the same as before. The action of this shutter is to decrease the atmospheric pressure on the gasoline in the carbureter bowl at certain throttle openings and to decrease the amount of gas freed through the spray nozzle at certain engine speeds.

Unchanged Features

To deal exhaustively with so well known a car would be absurd, except to point out the main features which it has vindicated. First of these is, of course, the eight-cylinder motor from a quantity production viewpoint, for if Cadillac did not *invent* the eight it certainly *created* it.

Second is the high-speed system of light reciprocating parts, big valves with a quick lift, horsepower peak at a rate of revolution approaching the 3000 mark and so on. Nobody before the coming of the Cadillac had attempted to apply these principles on such a wholesale scale, or to so large a motor, measuring by piston displacement.

Third may be put the very low high-gear ratio which enables the revolution possibilities of the motor to be utilized at practical road speeds, for here again Cadillac was a pioneer. The speed of the motor at a thirty-mile-an-hour road speed is higher than that of any European car, yet the engine has not suffered on account thereof.

Manufacturing Problems

No secret is made of the fact that Cadillac would have liked to make many more cars than it has been able to do, since first the eight program was commenced, but it is easy to realize how large an undertaking it was to equip the plant for the manufacture of a totally new kind of product. H. M. Leland has given some figures concerning this reorganization which show what large sums are involved in the development of an utterly new type of car and the amount of shop work to be done before the decks can be cleared for action. He says that the first three engines made for experi-

mental purposes cost $46,000 not including anything for overhead charges; and that the first three experimental cars cost $63,000 or $21,000 each.

In tool equipment the changes in the motor department called for 269 new machines costing over $180,000, and small tools like drills and cutters numbering over 50,000 by a wide margin. Add to this the clearing out of old equipment and the installation of the new and it follows that the cost of getting ready to commence manufacture must have been at least over $500,000.

From the engineer's viewpoint some figures of Mr. Leland's relating to drafting-room work will be interesting. The number of experimental drawings made was 1922, the total number of drawings up to March of this year, when production was in full swing, totaled 2283 and the number of tool drawings was 10,869. Of blueprints the total number made was 223,175 using 38½ miles of paper, and figuring on a normal day it would take one man sixty-four years to make the original drawings.

Over 10,000 Parts

In the whole Cadillac car there are, says Mr. Leland, more than 10,000 parts if those in the electrical apparatus are considered.

Practically No Motor Changes

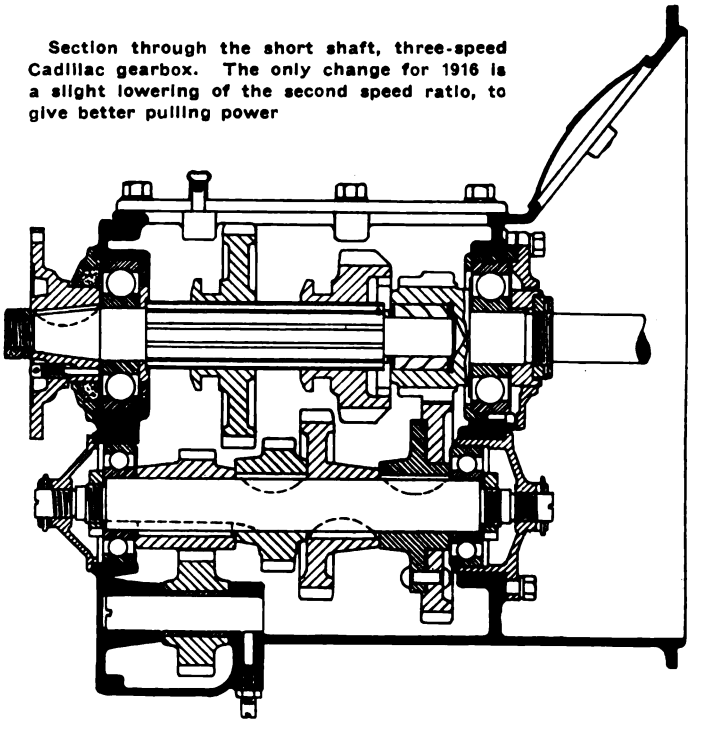
In the illustrations the changes are shown in the photographs and the new designs can be studied also in the drawings which lay bare almost every portion of the motor. Here the only change besides the redistribution of the accessories consists in bringing the flywheel ring gear to the central plane of the wheel, so as to allow the generator and starting motor to be moved aft. The fan shaft housing altered to suit the new location of the distributer and to provide a drive for the latter.

Just to recapitulate the unaltered motor specification, the dimensions are 3.125 by 5.125 giving a displacement of 314 cu. in., the forked type of connecting-rod is used, and there are only eight cams for the sixteen valves. The fact that this construction has not been altered in the least is interesting, because it has several times been suggested that the sixteen-cam motor with rocker arms eliminated was easier to build.

At the front end one wide, silent chain drives the camshaft, and a second chain takes care of the fan spindle and distributer drive, while the oil pump is driven by a skew gear direct from the crankshaft, being thus located at the extreme front end of the crankcase. The intermediate gear which lies between the crankshaft and the oil pump is on a cross shaft that has a water pump at either end, and the water circulation is controlled by thermostat.

On the gearshaft is mounted a sixteen-plate disk clutch, and this bolts to the flywheel when the bell housing is attached to the crankcase, it is a dry-plate type with alternate steel and wire mesh asbestos fabric surfaces and is sufficiently easy to operate to render starting from rest in high gear quite smooth. The gearset has no peculiarity, being just a robust three speed type with annular ball bearings. For the rear axle a Timken design is employed, certain parts,

1916 Cadillac seven-passenger touring car. Note straight top line. There is a new mud flap in front below the radiator protecting the water pumps from splash



Section through the short shaft, three-speed Cadillac gearbox. The only change for 1916 is a slight lowering of the second speed ratio, to give better pulling power

such as the spiral bevels, being made in the Cadillac plant. The propeller shaft is an open type with two universals. Drive is taken through the springs, but not torque, as a special stay is provided.

For the front axle and steering gear the detail work is very thorough and the bearing surfaces provided well up to the high speed work of which the car is capable. One little detail that often escapes attention is the adjustment for meshing the worm with the worm wheel in the steering box. As shown in the drawing, there is a small lever alongside the steering arm, locked to the frame side by a small bolt which can be passed through any one of five holes. Moving the lever oscillates an eccentric bushing on the worm wheel shaft and so sets the depth of tooth engagement. It is, of course, the sort of fitting that only comes to be appreciated after the car has been in use for a year or two, but it is very valuable then.

Great Reliability of Ignition

Almost needless to say, the electrical apparatus is all Delco and consists of the latest variety with no changes in principle from the outfit belonging to the former type. In the distributer the low-tension breaker has two blades which are joined up in parallel to halve the amount of current passing between the sets of contact points.

To complete the specifications: wheelbase is 122 in. and tires 36 by 4½ in. all around, and 56 in. is the standard tread though 61 in. tread can be obtained if desired. Gasoline feed is by air pressure supplied from a pump on the motor to a 20 gal. tank at the rear. Added to the five outside lamps and the dash lamp, the 1916 car has an opal glazed tonneau light, a Waltham clock and an inspection lamp. Recapitulating the prices, the seven-passenger touring car, the five-passenger salon and the roadster, each cost $2,080, the five-passenger brougham $2,950, seven-passenger limousine $3,450 and Berlin $3,600. A type that ought to be very popular is the three-passenger victoria, which has a most beautifully finished and fitted body with a leather top. The seating is arranged with the driver a few inches forward of the two passengers, who sit side by side and have plenty of width. This car costs $2,400 and, being either wide open or all closed at will, should be well worth the extra $320 to any man who does not want to carry more than three.

Weidely Four with Aluminum Pistons

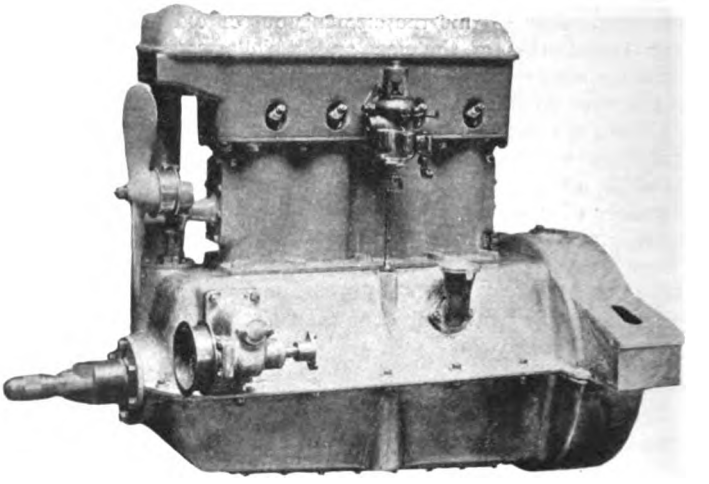
LIKE the six, the new Weidely four has all the valves in the head, without cages and operated by a camshaft lying above the cylinders, which camshaft is driven from the crankshaft by a vertical shaft, at the front, through worm gears, spirals at right angles, and the whole mechanism, shafting, gears, camshaft and valves completely inclosed and abundantly supplied with lubricant.

The cylinders are cast in a single block, the head likewise is cast integrally for the four cylinders and attached to the top of the cylinder block. Instead of casting the cylinders integrally with the upper half of the crankcase, as in the case of the older motor, this motor has them bolted to the upper half of the crankcase which is of aluminum instead of cast iron. This makes a better looking and much lighter construction. Practically all the water pipes and manifolds have been eliminated by the adoption of this style of casting.

The cylinder dimensions are 3⅜ by 5½, displacement 196.81 cu. in. The valves are exceptionally large for a motor of this capacity, especially as they are in the cylinder head. The outside diameter of the valves measures 2 1/16 in., and the clear opening is 1⅞ in. The valves have a lift of only 9/32 in. and are very short and light, weighing only 5.9 ounces each. This makes for a very smooth running and noiseless valve gear. There are no cages for the valves so the seats are efficiently water cooled. Each valve overhangs the cylinder bore slightly so that in the event of any breakage of the valve stems the valve head would not fall into the cylinder.

Valve Side Thrust Eliminated

No rocker arms are used, the camshaft being directly above the ends of the valve stems; but between the cams and the stem ends is a very light drop forged steel finger pivoted at the other end. This carries the adjustment by which the wear can be taken up and at the same time eliminates all side thrust on the valves due to the angularity of the cams.



Exterior view of Weidely four with side outlet carbureter

Tubular Connecting-Rods

The use of aluminum pistons and three-piece tubular connecting-rods is standard. The three pieces are electrically welded together. The pistons are also very light, weighing only 17 ounces with the piston pin in place. The latter is ⅞ in. in diameter and fastened into the piston.

The crankshaft is counterbalanced to offset the vibrations which occur at high engine speeds. The main bearings are oiled by force feed but the crankpins receive oil through the banjo rings which are attached to the cheeks of the cranks.

The flow of oil in these is governed by the speed of the engine as centrifugal force throws the oil from the rings into the pins. A 5-in. flange is provided at the rear end of the shaft to fasten the 16-in. pressed or rolled steel flywheel. On a high speed type of engine steel has been found necessary for perfect safety. It also provides material for the starting gear. The main bearings are all 2⅛ in. in diameter and from front to rear have the following lengths, 2 7/16, 2½ and 4 in. The connecting-rod bearings are 2 in. in diameter and 2¼ in. long.

The oil pump is located in the bottom of the case and draws its supply of oil through a screen in the sump. The two gears of the pump are of different size; the larger one serves as a distributer and forces the oil through four separate leads, three going to the main bearings and the fourth to the hollow camshaft. The latter is drilled through on the back of each cam so that each valve and its mechanism runs in a bath of oil all the time.

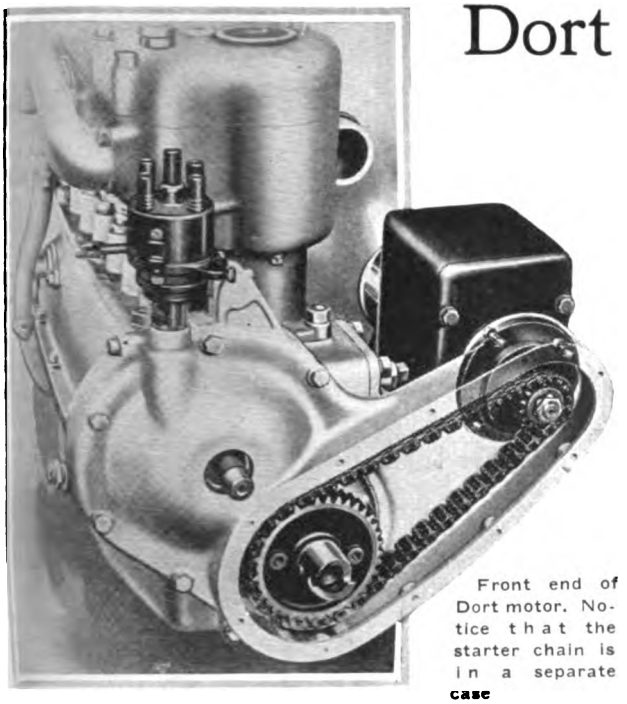
Dort Continues Roadster and Touring

Prices Reduced and Electric Starting and Lighting Fitted as Standard Equipment for 1916



Front end of Dort motor. Notice that the starter chain is in a separate case

ROADSTER and touring car models made by the Dort Motor Car Co., Flint, Mich., for 1916, show no changes in design over the 1915 types. The price of the touring car, however, has been reduced to $650 with full equipment, but the roadster still costs $540 with electric starting and lighting. Up to this time, the touring model has sold for $680 without starting apparatus or demountable rims. As the new price includes these, and they previously added $50 to the price, the real reduction figures to $90.

These Dort cars, which have a number of special features about them, are completely designed by the concern's engineering department. Though the firm name is comparatively new to the industry, the first models having made their debut at the national automobile shows this year, the Dort company is really composed largely of the same stockholders as the Durant-Dort Carriage Co., which has been prominently connected with the carriage industry for 28 years, it is said. In fact, a great deal of the manufacturing is done in the same plants, so that the Dort machines really come from an established manufacturing organization, and the taking up of motor vehicle manufacture is but a logical step.

Similar in Design

So far as general design is concerned both the roadster and touring car follow the same lines, although the roadster chassis is shorter and lighter and its motor is smaller. The aim has been to adapt each chassis specially to the class of service it is called upon to deliver. Naturally, a roadster does more running around and it can very logically be built lighter to promote economy of operation.

The touring model, in which a test run was made, has an exceedingly sweet-running power plant which handles the car in excellent shape with a surprising lack of vibration and noise. Of moderately high-speed type, this motor showed itself to be very flexible, coming down to a 4-mile gait without any hesitation and holding it, with rapid acceleration possibilities to above 50 m.p.h. There are several constructional features of the engine which undoubtedly have a bearing upon its performance, and these will be mentioned later.

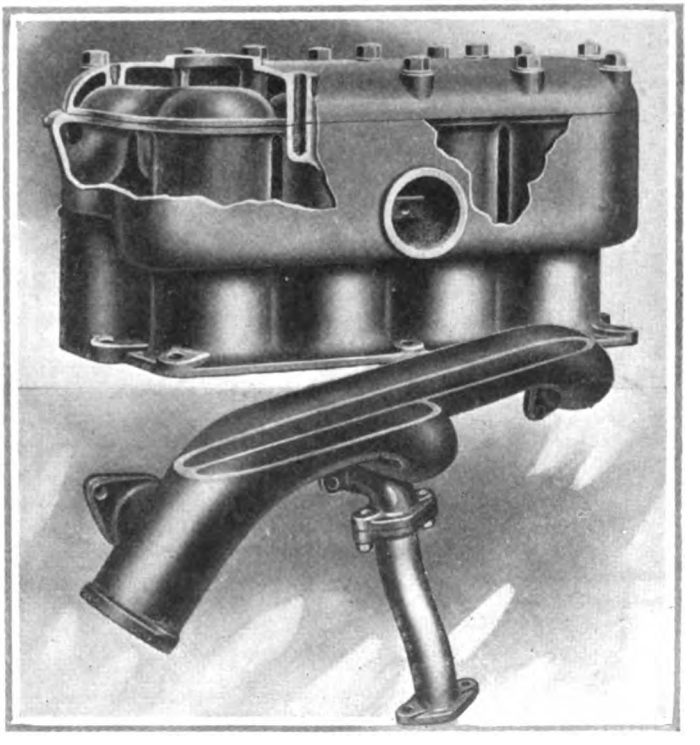
Following the specifications, the touring car, known as model 5, has a 3¼ by 5 motor, wheelbase of 105 in., cantilever rear springs, cone clutch, three-speed center control gearset, three-quarter floating rear axle, and 30 by 3½-in. tires. The roadster is fitted with a 3 by 4 engine, follows out the same general specifications, and its wheelbase is 92 in. This car is designated as model 4.

Detachable Cylinder Head

The Dort motor used in the touring car is capable of 20 hp. at 1000 r.p.m., while at 1600 r.p.m. it develops 28 hp. It is rated at 16.9 hp. S. A. E., and the displacement is 165.9 cu. in. The unit power plant construction is carried out with the gearbox and clutch attaching to the engine proper and all being supported on three points. Somewhat unusual is the use of a detachable cylinder head along with separate aluminum crankcase. Ordinarily when the head is made detachable, the cylinders and upper half of the crankcase form one piece, but the Dort design should be lighter through the use of more aluminum.

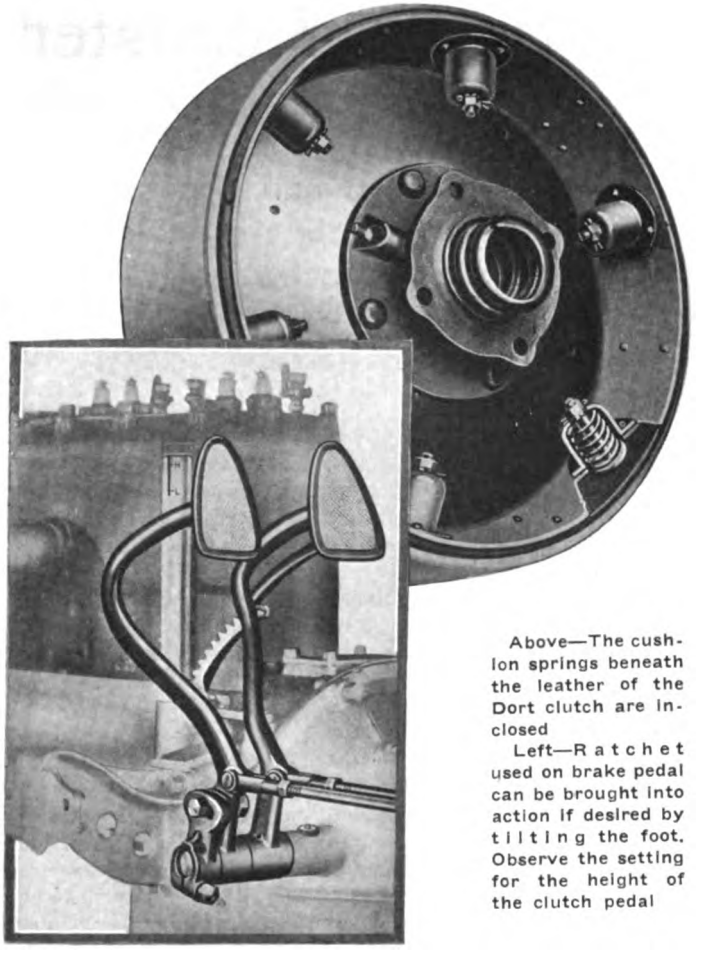
A striking feature of the motor is the use of an extra heavy crankshaft for its size, this serving as a big factor against vibration. It is a drop forging of 0.40 to 0.50 carbon steel and 1¾ in. in diameter, supported by two main bearings. Likewise the connecting-rods are forged from the same steel, and accurate balance of all of the reciprocating parts is said to be demanded to within ¼ oz. Long pistons are fitted, these serving to distribute the wear and reducing it to the minimum. Three rings are used on each piston, all above the wristpin.

The valve outfit does its part in giving the motor its high power. They are of large size—1 11/32 in. in the clear—



Upper—Cylinder block of Dort motor showing the extra large water spaces

Lower—Special exhaust manifold which separates the discharge so that from one cylinder does not interfere with free outlet from the next



Above—The cushion springs beneath the leather of the Dort clutch are inclosed

Left—Ratchet used on brake pedal can be brought into action if desired by tilting the foot. Observe the setting for the height of the clutch pedal

and have a lift of ¼ in. In their makeup, carbon steel stems are welded to the cast-iron heads, the two-bearing carbon steel camshaft operating them through the intermediary of mushroom lifters.

Motor dimensions follow:

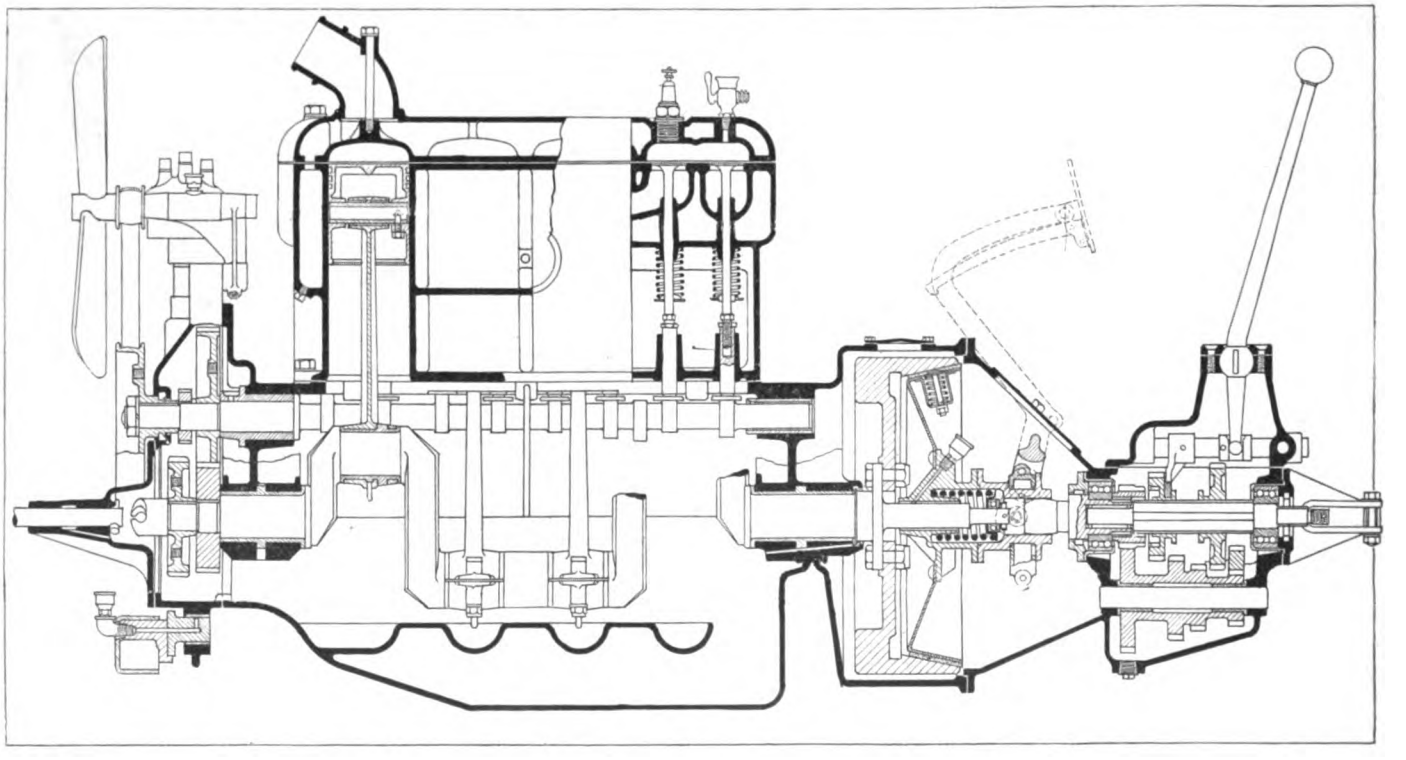
	Model 5—3 1-4 by 5	Model 4—3 by 4
Front crankshaft bearing	1 3-4 by 3 5-16	1 3-4 by 2 11-16
Rear crankshaft bearing	1 3-4 by 2 11-16	1 3-4 by 3 7-16
Front camshaft bearing	1 1-4 by 2 31-32	1 1-4 by 2 1-4
Rear camshaft bearing	1 by 2 31-32	1 by 2 27-32

Special attention has been given to the matter of uniform waterjacket space around each of the cylinders of the motors. The detachable head feature helps in this respect, for it permits of the making of accurate casting, so far as the waterjacket thickness is concerned. Equal spacing is secured all around each of the cylinders, making for uniform expansion of the cylinders all around with no distortion, which is apt to happen if cylinders Nos. 1 and 2 and Nos. 3 and 4 are close together, for instance. This unequal spacing, with the two front and the two rear in groups is sometimes found, and naturally expansion cannot be uniform in such a block arrangement.

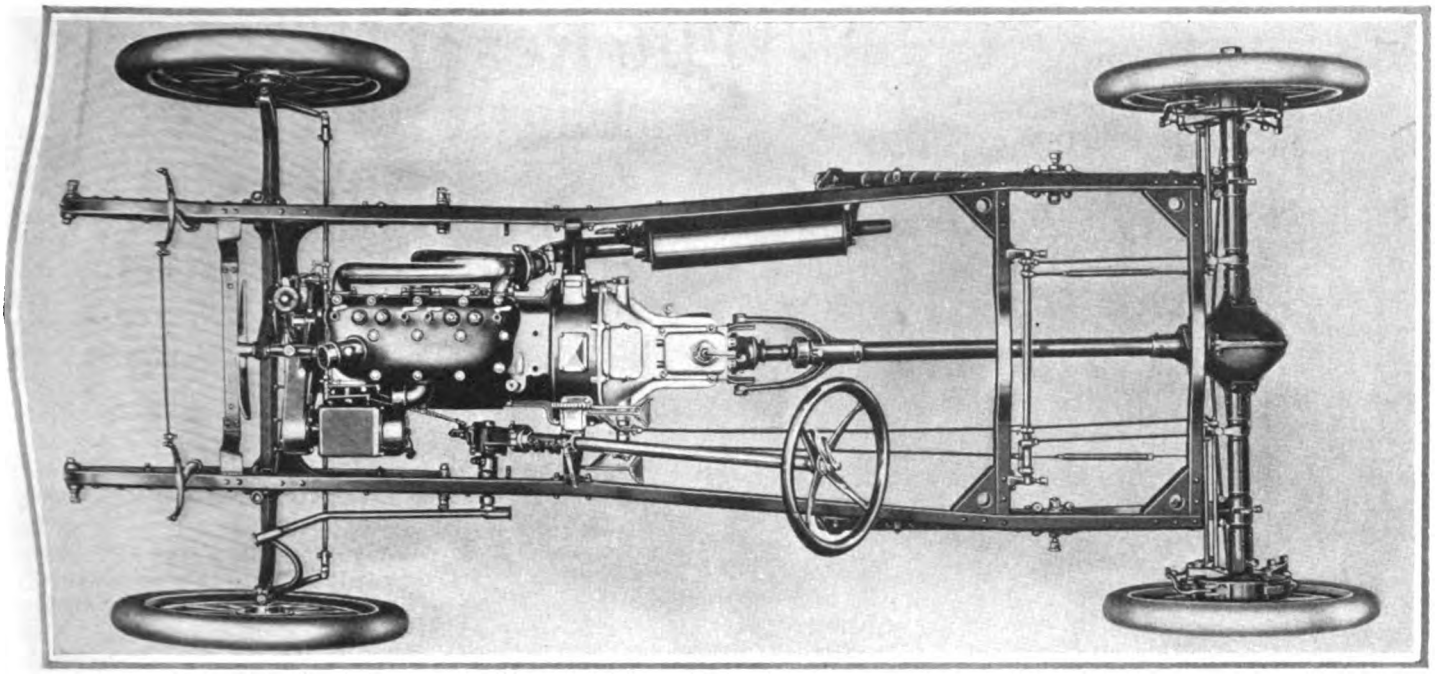
Double Exhaust Manifold

Unusual in four-cylinder construction is the double exhaust manifold, also. This is on the same order as the double designs often used with sixes, only instead of three cylinders exhausting into each passage, two cylinders use each outlet. The two passages are cast integrally with an inner wall between them. The object of the design of manifold is to prevent any back pressure in the motor. Cylinders Nos. 1 and 4 exhaust in one passage and Nos. 2 and 3 in the other. As the firing order is 1, 3, 4, 2, there is no possibility of exhaust gases from one cylinder running into the flow of gases from the preceding cylinders. In short, free outlet is assured.

Dort motors are lubricated by the constant circulating splash arrangement, whereby a pump operated from the camshaft draws oil from the reservoir at the bottom of the motor and forces it to the front gear casing, from which point it flows to the troughs under the connecting-rods and is picked up by the dippers on the ends of these. This serves to splash the oil to the main bearings, rod bearings and all other friction surfaces. Convenience for the driver has not been overlooked in the location of the oil gage which is combined with the breather. Placed on the left rear side of the crankcase, this combination is really a tall standpipe, with the indicator brought almost to the top of the cylinders,



Section of Dort Model 5 touring car power plant. Motor is 3.25 by 5 in. and has a detachable cylinder head



In this chassis plan of the Dort model 5 the frame is widened so that the cantilever springs are located beneath the side rails

making it easy to read the lever without getting the head down under the hood.

The Electrical System

The electrical system has for its main unit an Apple motor-generator carried on a bracket on the left forward side of the engine and driven by an inclosed silent chain from the crankshaft at a 2½ to 1 ratio. A simple adjustment of the chain is provided so that the chain centers can be varied.

A neat cone clutch has been designed for these cars. This has a leather-faced pressed steel cone with six compensating spring plungers pressing upon the leather at equal intervals around the circumference, and making for an easy action of the clutch on engaging. Each of these spring plungers is inclosed within a cup pressing which is attached to the cone, and the ends of the plungers extend through the cups to admit of adjustment of the spring tension. They carry adjusting nuts, held in place by cotters. The clutch pedal engages and disengages the clutch through a hollow phosphor-bronze collar, which is so arranged as to be kept constantly filled with grease through the fitting of a tube running to the outside of the gearcase so that it is an easy matter to reach the large grease cup supplying the collar through this tube.

In fact, lubrication of the gearset is well cared for, as a small elbow is fitted, this making it easy to put in the transmission oil. In the internal makeup of the gearset there is nothing departing from the conventional. The gears and shafts are formed from nickel steel, and the mainshafts run on ND bearings.

From the power plant, the drive system is still strictly Dort design throughout. Fitted with a universal just back of the gearbox, the driving shaft then enters a substantial torsion tube, the front end of which is of yoke form. The arms of the yoke are carried in brackets on either side of the gearbox end, and with freedom of end play to the extent of ¼ in., this to take care of axle variations.

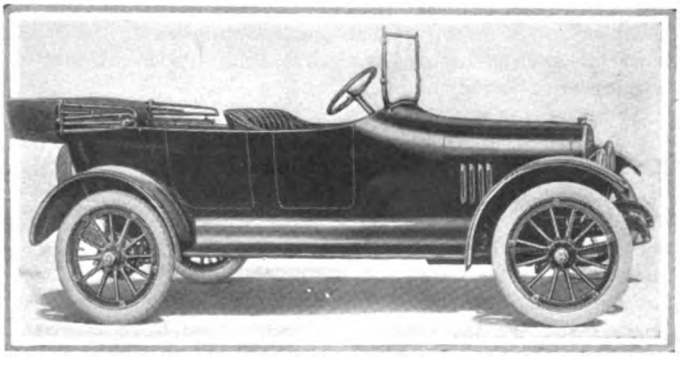
Axle Bearings Easily Adjusted

A special feature of the rear axle construction is that all bearings are adjustable from the outside, which is a point that cannot be too highly commended. In addition a special opening has been provided in the housing to enable the driver to see that the bevel gears are properly meshed. To allow for this external adjustment, a pin passes through the housing to a groove in the bearing carrier, and when this is unscrewed, the carrier can be turned through the opening in the housing thus made, bringing another groove into position for locking with the pin when the latter is again screwed into place. In the construction of the axle, differential gears are made of nickel steel, and propeller and differential shafts are of chrome nickel. The propeller shaft is carried on ND double and single-row bearings, with the differential and wheels running on Hyatts.

One Pedal for Clutch and Brake

Brakes are 10 in. in diameter with the service set external contracting and the emergency internal expanding. The service brake operates from the clutch pedal. Pushing the pedal halfway disengages the clutch, and further movement acts upon the brake. The emergency brake system is operative from the other pedal with a ratchet holding it in place when required. To release this brake, the lower part of the pedal is pushed, causing the ratchet to let go. By this arrangement of the brake controls, a second lever beside the gear change lever is eliminated.

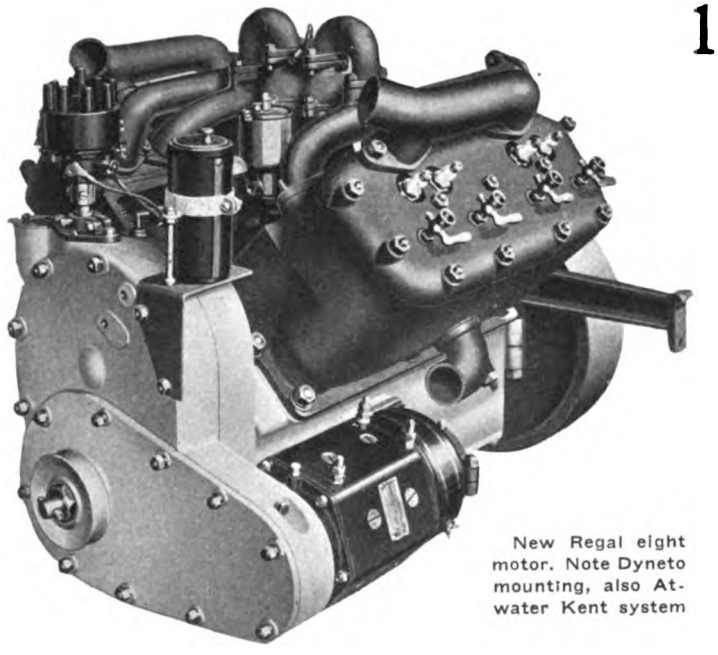
Cantilever rear springs are well applied to these cars. The springs are of the full type, shackling at the front to the frame, and having a trunnion attachment at the center. They measure 50¼ in. long by 2 in. in width on the touring car and 45¼ by 1¾ in. on the roadster chassis. Front springs are conventional half-elliptics. In appearance, the Dort models are very attractive, with hood sloping in unbroken curve from the cowl.



The Model 5 Dort touring car has a clean cut appearance

1916 Regal Line Is An Eight and Two Fours

All Three Motors Have Detachable Cylinder Heads—Dyneto Fitted—Valves in 8 at Angle



New Regal eight motor. Note Dyneto mounting, also Atwater Kent system

AS announced recently, the program of the Regal Motor Co., Detroit, Mich., comprises two fours at $650 and $985, and an eight at $1,200. Of these the big four is practically identical with the 1915 chassis described on page 1277 of THE AUTOMOBILE for June 18, 1914. The main change is in the electrical equipment which is now a Dyneto single unit combining the functions of lighting and starting. Ignition is cared for by an Atwater Kent automatic advance distributer located at the front end of the camshaft as in the last model. Of course, the Dyneto does not need a flywheel drive since it lights and starts on the same gear ratio, so it is driven by a chain from the front end of the crankshaft. This chain has an aluminum case which holds lubricant, and there is a simple adjustment for chain tension, the generator being mounted on a rocking pivot so that a turn of a nut suffices to set the centers.

This Dyneto outfit is used on the eight and on the small four also, the mounting being practically identical with the same means for adjustment. In the case of the eight it is not placed between the cylinder blocks, but is attached to the crankcase very much as on the fours, so its comparatively large size does not interfere with valve accessibility.

Turning to dimensional detail, the smaller four has a bore and stroke of 3⅜ by 4¼, the large four 3¾ by 5 and the eight 3 by 4½ in., giving displacements of 134, 221, and 254 cu. in. respectively. The wheelbase of the light four is 106 in., and that of the other two cars 112 in., while the tread is 56 in. in each case. Naturally the light four has a smaller body than the larger model, but the eight and the large four have almost the same body equipment.

As regards the chassis detail, the smaller car differs from the other two which are alike, but it is pointed out that the cheapest car is merely a little more simple in outline as the material and parts used are thoroughly good and well in keeping with Regal quality.

As before the standard or large four is made in the Regal plant but the small four and the eight are the New Port Huron motors, so the eight is more like the new four than it resembles the old one. All three engines have detachable cylinder heads covering valves arranged in the normal manner and a Stewart carbureter is used for each, with the addition of a vacuum feed except for the light four, the latter having a gasoline tank in the cowl, instead of beneath the front seat. On the eight the vacuum feed tank is located under the dashboard so it is accessible from the back. In this position it occupies space that would otherwise be wasted and its absence from under the hood aids the accessibility of the motor. As for accessibility, on the Regal motor the tappets could all be adjusted without removing any part, and if the carbureter were removed together with the intake pipe the job would be really easy. The removal of the carbureter is, in itself, so simple a proceeding that most men would take it off if they were about to set the whole sixteen tappets, though if it was a question of one or two only it would not be worth while.

On the fours the accessibility is marked and the placing of the carbureter on the valve side does not interfere with the valves.

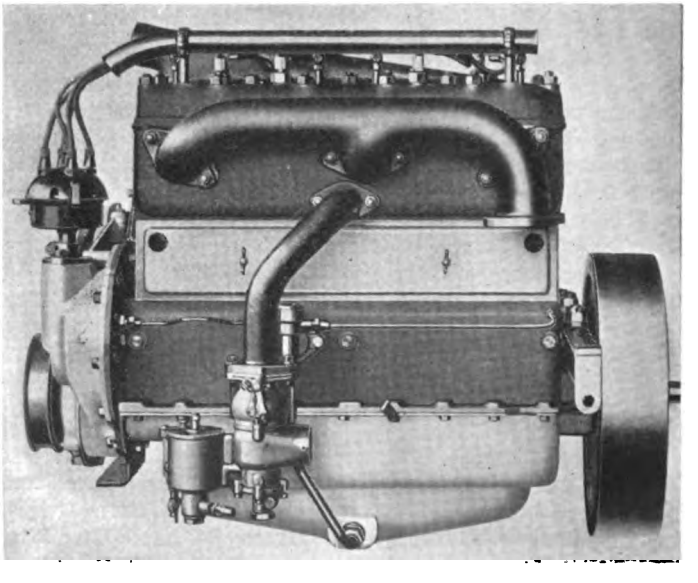
Unique Camshaft Arrangement

It has been pointed out once or twice that when the angle between the cylinders of a V-type engine is 90 deg. the sequence of valve operations is at 135 deg. so that one cam can operate two opposite valves if the camshaft is placed high enough to put the valves themselves at 135 deg. With a big motor this might be difficult because of the great amount of space it would make between the crankshaft and camshaft, but the idea has been worked into this motor very neatly. Having the valves at a larger angle than the cylinders also has the beneficial effect of inclining the pockets with reference to the cylinder bores and so cutting down their area. Of course this inclination of the valves so much further toward the horizontal makes tappet adjustment easier than ever.

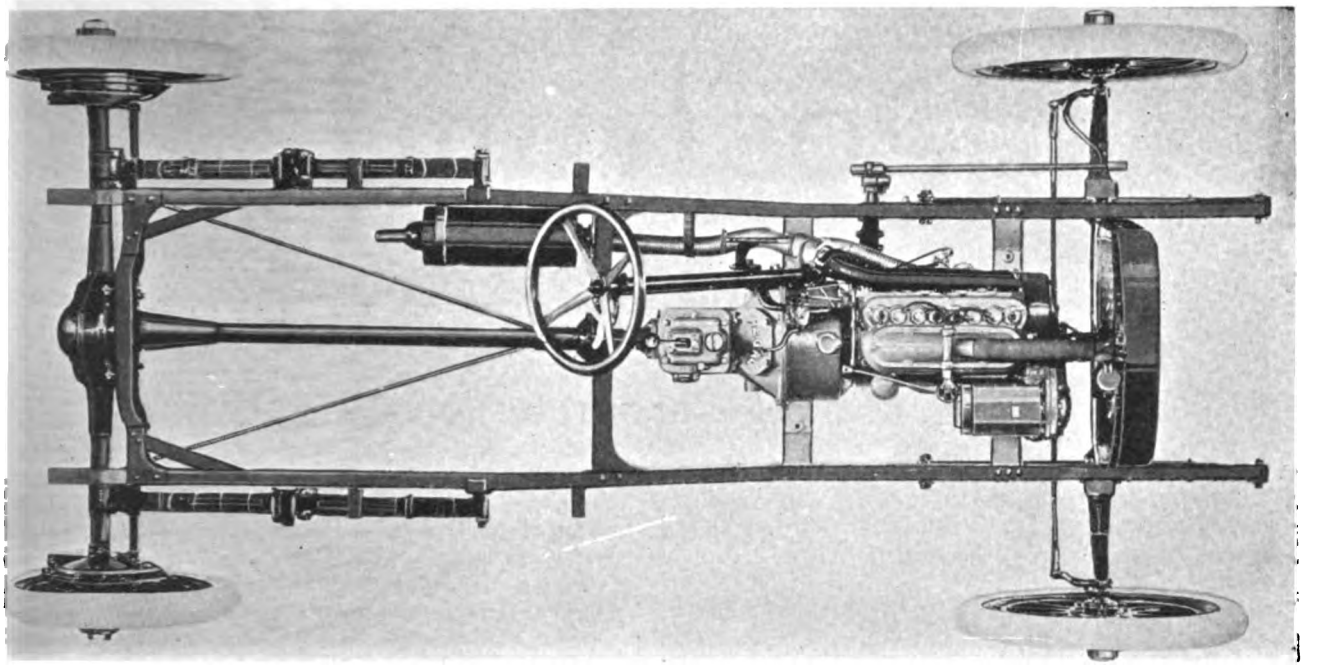
Helical spur gears are used for the camshaft drive on all models the materials being steel in cast iron.

Lubrication Systems Differ

For the light four the lubrication is splash, the level in the dip troughs being maintained by a plunger pump driven



Intake side of 1916 Regal four block motor



Plan for 1916 Regal four-cylinder chassis, showing compactness and simplicity of assembly

of the camshaft. On the big four the rear main bearing and the rear camshaft bearing have a force feed from the plunger pump, while the other two crankshaft and the camshaft bearings have pockets to catch splashed oil. Troughs and connecting-rod dippers are used in addition to insure ample and constant lubrication.

For the eight there are two separate plunger oil pumps located side by side on the front end of the motor these forcing to the main bearings on the crankshaft of which there are two. The crankshaft is drilled to the pin bearings and there are dip troughs also, as in the larger four. In both these pump leads see to the supply for the front end gears and the Dyneto chains.

Two Universals

Like the large four of 1915, the 1916 model and the eight have transmissions located on the rear axle and the driveshaft is inclosed in a torque tube. Unlike most constructions of this kind there are two universals, the torque tube being attached to the frame by a fork with two pivot bearings. There are no bearings between the driveshaft and its inclosing tube so the cutter acts simply as a protective covering and to take the twisting stress of the axle.

Small Four Has Unit Power Plant

For drive stresses two radius rods are arranged between the axle and the side rails of the frame so all possible stresses are cared for. The construction is as far from a Hotchkiss drive as it very well could be. The small car is different, having a unit power plant and a slightly different rear axle as will be seen in the chassis illustration. The axle is a [illegible] pattern with ball bearings throughout.

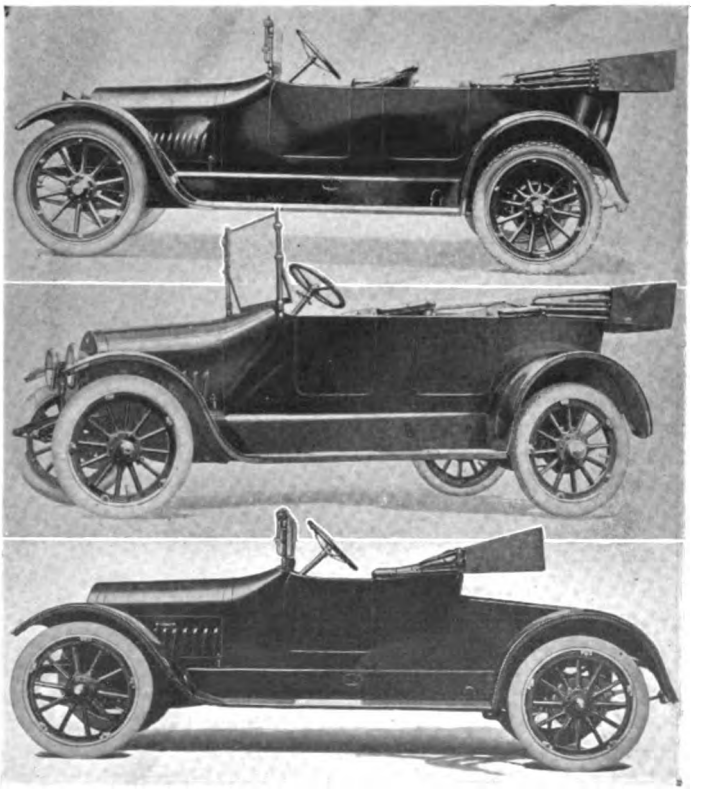
[illegible] have leather faced cone clutches, the two larger [illegible] provided with cushion springs beneath the

[illegible]ing Body Work

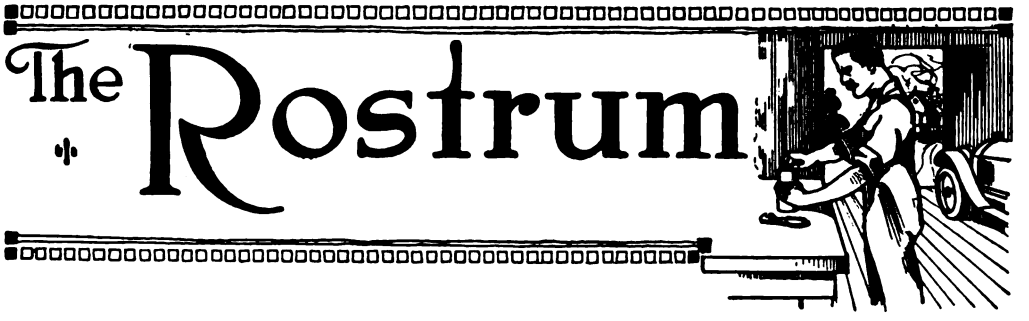
[illegible] four and the eight have almost the same five-[illegible] body and the keynote of their style in low ap-[illegible]. A fairly straight line side with an easy curve on [illegible] running smoothly into the hood, domed fenders and [illegible] of any sharp contrasts of curvature are characteristics. Internally there is plenty of leg room and a good depth of upholstery. The light four has a body on somewhat the same lines but smaller, of course. Two details of the larger bodies which add greatly to the smart appearance are the all-aluminum toeboards in the driver's compartment and the use of black enamel running boards with heavy aluminum treads opposite the doors.

Tire equipment is as follows: Light four, 30 by 3½; Standard four, 33 by 4, and eight, 33 by 4, all on demountable rims with the spare rim carrier at the back of the body.

Mohair tops are used on all three cars, the two large ones having Jiffy curtains and all three are a single sort of one-person design.



Top—Regal eight touring car, which sells for $1,200. Middle—Light four touring car listing at $650. Bottom—Roadster body fitted to any of the three chassis



Adjusting Marvel Carbureter on 1915 Buicks

EDITOR THE AUTOMOBILE:—Will you please send me directions for adjusting the Marvel carbureter used on the 1915 Buick six. The engine runs well, but will not throttle down and run slowly on high.

Wytopitlock, Me. A. E. B.

—In general if a motor will not fire regularly at idling and low speeds, it is not securing a sufficiently rich mixture at this time. On the Marvel carbureter the primary gasoline adjustment which affects this is at the bottom and is in the form of a turn screw with a cross handle. It is directly under the center of the carbureter. This adjustment should be turned slowly to the right or left until the motor runs smoothly at idling speed. Since turning to the left allows more gasoline to pass through the needle valve, it would probably be necessary for you to turn it slightly in this direction to secure the proper adjustment.

If you desire to start from the beginning, and adjust the carbureter, the following directions will apply: Start by turning needle valve A, to the right until it is completely closed, an air adjustment B to the left until end of screw is even with end of ratchet set spring above it. Next open needle valve A one turn. Start the motor as usual, using choker button, if necessary. Allow the motor to warm up, then with spark retarded, turn adjustment A to the right until motor runs smoothly.

After the motor has warmed up, turn air valve adjusting screw B to the left, a little at a time, until motor begins to slow down. This indicates that the air valve spring is too loose. Turn it back to the right just enough to make the motor run well.

To test the adjustment, advance spark and open throttle quickly. The motor should take hold instantly and speed up at once. If it misses or pops back in the carbureter, open needle valve A slightly by turning to the left. Do not move air adjustment screw B any more unless it appears absolutely necessary.

The best possible adjustment has been secured when air adjusting screw B is turned as far as possible to the left and needle valve A is turned as far as possible to the right, provided the motor runs smoothly and picks up quickly when the throttle is opened.

If the motor runs too fast with throttle closed, turn small set screw in throttle stop to the left. If motor stops when throttle is fully closed, turn the set screw to the right.

As the throttle opens, the hot air damper, which is connected to it by a link gradually closes, the greatest amount of hot air passing through the jackets when the throttle is nearly closed. The position of the hot air damper, at any time, is indicated by the slot at the end of the damper shaft. By loosening the set screw in the damper lever, this can be set for any desired relation between the damper and the throttle.

Motor Does Not Carbonize Quickly

Editor THE AUTOMOBILE:—How quickly will sufficient carbon collect in an automobile motor, so as to make it necessary to clean out the cylinders?

2—In the average life of a motor, how many times must carbon be burned out?

3—What is the average cost for burning carbon out of motors as per the following: four-cylinder, six, eight and twelve?

4—Are there any preparations on the market for mixing with the gasoline that will eliminate carbon without danger to the motor?

5—If possible, would like the names and prices of preparations in connection with question four.

N. Y. F. M. L.

—In a new motor it should not be necessary to clean out the carbon more than once in 3000 miles. As the motor becomes older and the piston rings wear forming an oil seal which is less tight, more oil works its way into the combustion chamber with the result that carbonization is more frequent and cleaning will have to be resorted to more often. The estimate of 3000 miles is a very liberal one as there are many new cars which run 5000 and 6000 miles without carbon trouble sufficient to require the cylinders being scraped or burned out. As a general rule, it is a good thing to clean out the carbon when the valves are ground. The two operations can be readily performed at the same time because with the valve caps removed, or with the cylinder head taken off as is done in some motors, the combustion chambers are accessible and can easily be scraped out.

2—As stated under question 1, this will depend entirely upon the condition of the motor. Some motors with leaky rings become so full of carbon after 300 or 400 miles that they start to pound and pre-ignite to such an extent that they cannot be sufficiently operated.

3—The average charge for burning out a four-cylinder motor is $2, a six $3, an eight at $4 and a twelve $6. This is based upon the charge generally made in garages of 50 cents per cylinder. The time required for this work is very short as with the use of the oxygen tanks it is only necessary to insert the lighted paper into the combustion chamber and then by use of the oxygen, combustion is immediately started and is quite rapid.

4—There are patented preparations on the market for mixing with gasoline which are stated not only to remove carbon but to increase the mileage. The danger of securing materials which will have a deleterious effect on the cylinder walls is so great that the nature of these preparations should be carefully scrutinized before they are used. A method of

removing carbon by kerosene which has been tried out with good results is to start the motor and then with the kerosene in a cup or some other small vessel, the quantity is poured into the air intake as the motor is running. While this is being done, the throttle is opened wider to prevent the motor from stalling as it will begin to splatter as soon as the kerosene begins to enter the manifold. The work should be done somewhere where it does not make much difference if the motor should smoke as the introduction of kerosene will cause large volumes of smoke to pour from the exhaust. It is also a good idea in doing this work to open the muffler cutout so as to prevent soot from filling the muffler.

5—This question is answered under the preceding.

Can Not Make a Solid Connection

Editor THE AUTOMOBILE:—In THE AUTOMOBILE for June 24, I have not secured exactly the information desired.

The meaning of my question in the Rostrum is,—would any harm result if I removed grease cups, and put metal bushings enough around the axle housing to keep it from moving while running the car.

I have investigated several cars and do not find any movable parts on the spring seats, and wondered if this could not be tightened on my Buick B model 36.

Angelica, Wis. J. L. DECOCK.

—The flexible connection here is necessary, as, were the connection solid, strains would be put on the springs and driving members which should not be encountered by them. This connection for the spring was designed to fit in with the other members of the rear system and therefore, should not be altered.

Transmission Losses Are Very Small

Editor THE AUTOMOBILE:—In trying to work out a proposition of hydraulic transmission of power, we are anxious to learn if possible what the percentage of loss is in the present gear driven and worm driven cars from the motor to the rear wheels?

Nashville, Tenn. J. S. F.

—It has been estimated that in the car having an average amount of use, the loss from the motor to the rear wheels is approximately 5 per cent. The exact loss is determined by a number of factors, however, which vary. One of these is in the universal joints which have greater losses as the drive departs from that of a straight line. Some companies state that in worm drive the losses are 2 per cent larger on loads ranging from 8 to 45 hp.

Specifications of Buick, Ford and Franklin

Editor THE AUTOMOBILE:—Kindly answer the following: Can you give me the numbers of the patents which have been taken out on the Air-Friction Carbureter now made in Dayton, Ohio?

2—What is the bore, stroke, gear ratio and kind of axle in the Buick model 19, five-passenger car?

3—What is the bore and stroke, also the gear ratio of the Ford?

4—What is the bore, stroke and gear ratio of the Franklin?

5—What kind of valves are used in the Franklin engine?

6—What is it which makes the economy of the Franklin?

7—What is the boiling point in deg. Fahr. of gasoline?

8—What is the boiling point in deg. Fahr. in kerosene?

Barberton, Ohio. O. H.

—THE AUTOMOBILE has no records of these patents.

2—Buick 19 model had a bore of 4¼ and a stroke of 4½ in. The cylinders were cast in pairs. The car was equipped with a tubular radiator, both magneto and dry battery ignition, cone clutch, selective three-speed gearset, and had a wheelbase of 105 in. with standard 56-in. tread. The tires were 32 by 4.

3—The Ford motor is 3¾ by 4. It is L-head block and geared 3.63 to 1. The wheelbase is 100 in.

4—The bore, stroke and gear ratio of the Franklin cars are as follows: 3⅝ bore, 4-in. stroke and gear reduction 3.69 to 1 to 1.

5—The valves are overhead.

6—The principal economy feature in the Franklin car is the lightness due to the selection of materials, air cooling and other features of design. In explaining the effort to secure economy, the Franklin company states the following:

"To move an automobile which has a tendency to remain stationary by virtue of its own weight, energy must be employed. The drag exerted by the contact of the wheels with the ground and the friction of the moving parts must be overcome by energy, and the source of energy itself must secure the greatest proportion of power which is in the fuel. To secure the most power from gasoline, little or no heat developed by the combustion of the fuel that can be changed into work should be lost; and due to direct cooling on these cars, a small percentage is thrown away. The efficient temperature of operation of a Franklin motor is 350 deg. Fahr."

7—The boiling point of gasoline varies with the gravity and hence it is impossible to give a boiling point which will cover many different grades of fuel. One hundred and fifty deg. Fahr. has been frequently given as the boiling point of common gasoline. Benzine it is stated has a boiling point of 176 deg. and kerosene of the highest grade, 185 or 190. These quantities are only estimates, however, and cannot be taken as mathematically accurate for any definite grade of gasoline.

Tangent of Tank Angle the Factor

Editor THE AUTOMOBILE:—We have a Thomas-Detroit which we are changing into a raceabout, having dropped the seat and placed the tank on the top of the chassis, and we would like to know if you could advise the amount of drop from the bottom of the tank to the carbureter which would be necessary in order to get a free flow of gas on all hills.

The tank was originally underslung with a forcefeed, but for some reason this was disconnected—probably because it did not work, although I have heard that the pump on this car was eminently satisfactory, and I want to know whether or not it will be necessary to rerig this up in order to take care of a steady flow of gas at all times and on all hills.

Williamsport, Pa. H. W.

—The distance of the bottom of the tank above the car-

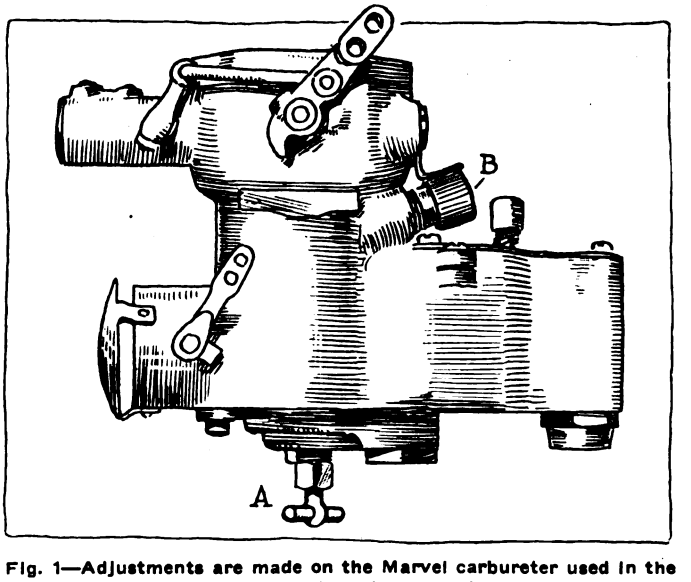


Fig. 1—Adjustments are made on the Marvel carbureter used in the Buick six at the points A and B

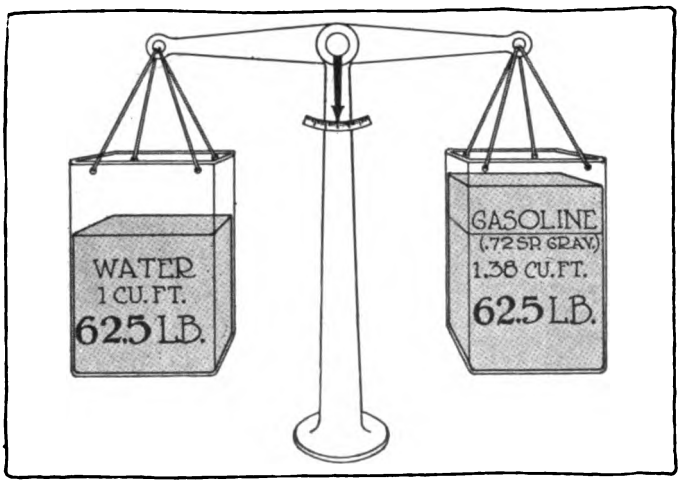

Fig. 2—A volume of gasoline must be 1.38 times as large as a volume of water to weigh the same amount if the specific gravity of the gasoline is 0.72

bureter is not the only factor which controls the flow of gasoline. Strange as it may seem at first, the distance of the tank behind the carbureter has just as much influence on the angle of the grade that the car may climb as the height has. To express the proposition definitely, the angle at which the car can climb, for any given tank location, depends upon the height of the tank above the carbureter vertically divided by the distance of the tank back of the carbureter horizontally. If, for instance, a tank is 12 in. above the carbureter and 2 ft. back of it, the determining factor would be 12 divided by 24 or 0.5. If the tank on the other hand were 3 ft. back of the carbureter, the determining factor would be 12 divided by 36 or 0.333. As will be noted this factor becomes less and less as the tank is further back of the carbureter. This fact becomes more evident still, if you will consider a tank which is a foot above the carbureter directly above that instrument and compare it with a tank which is a foot above the carbureter, but mounted in the rear of the car. It is evident that a better flow will be had from the tank directly above the carbureter on a slope of any steepness.

To bring the matter down to actual figures, if the height above the carbureter divided by the distance back of the carbureter measured vertically and horizontally respectively equals 0.176, the car will be able to climb anything up to a 10 per cent grade. If that figure equals 0.268 it will be able to climb anything up to 15 deg. If the figure is 0.364 the gradient will have to be 20 deg. before flow ceases and if the figure is 0.578 the flow would not cease under 30 deg.

Weight of a Gallon of Gasoline

Editor THE AUTOMOBILE:—Would you kindly inform me how much a gallon of gasoline weighs, the gravity being 0.72?

San Francisco, Cal. J. R.

—If, when speaking of gravity, you refer to the specific gravity scale the weight of a gallon of gasoline of 0.72 specific gravity would be 6.001632 lb., taking water at the specific gravity 1 to weigh 8.3356 lb. per gallon. On the other hand, if you mean 0.72 gravity on the Baumé scale, this would be equivalent to about 0.69 specific gravity. Gasoline of 0.69 specific gravity weighs 5.751564 lb. assuming that a gallon of water of specific gravity 1 weighs 8.3356 lb.

It is generally taken that a cubic foot of water distilled, weighs 62.5 lb. although the actual weight is somewhat below this. If the gasoline is 0.72 specific gravity, it would take 1.38 cu. ft. to weigh 62½ lb. In other words, the volume of gasoline to weigh the same amount as a given volume of water must be 1.38 times as large if the specific gravity is 0.72. This is graphically brought out in Fig. 2.

Gasoline of 63 Baumé is in common usage and for calculation in regard to the weight for any definite quantity of gasoline of this gravity, a handy chart is given in Fig. 3. Referring to this, it will be seen that the weight is very close to 6 lb. to the gallon and in making any approximate determinations of the weight of the various tanks filled with gasoline, 6 lb. to the gallon can be taken as sufficiently accurate.

If you desire to determine the weight of gasoline for any specific gravity, referring to gallon, it is only necessary to multiply the figure 8.3356 by that specific gravity. This figure is the weight of water since the specific gravity of water is 1, multiplying by the specific gravity of the liquid of which you wish to find the weight will give you the desired results. In case you only have the specific gravity in terms of the Baumé scale, it will be necessary to secure the specific gravity from a conversion table. The Baumé scale is so arranged that 10 Baumé corresponds to 1 specific gravity. In other words, water would be 1 on the specific gravity and 10 on the Baumé scale. Ninety on the Baumé scale is 0.6363 specific gravity. If you desire to secure the specific gravity from the Baumé scale, and have not a conversion table at hand, it can be found readily by the formula:

$$\text{Specific Gravity} = \frac{140}{130 + \text{Be}'}$$

For example, if your hydrometer showed the gasoline to be 64 Baumé, and you desired to find the specific gravity by means of the above formula, you would divide 140 by 130 plus 64 or 140 by 194. The result of this division is 0.7216, which is the specific gravity of a liquid 64 on the Baumé scale. To find the weight of a gallon of a liquid of this gravity you would multiply 8.3356 by 0.7216, which would give you 6.03+ lb.

Horsepower of Two Cylinder 5 by 6½

Editor THE AUTOMOBILE:—What is the horsepower of a two-cylinder motor with 5-in. bore and 6½-in. stroke at 750 r.p.m.?

2—What type of radiator gives the best results on a 16-hp. gasoline tractor and what capacity should it have?

Fingal, N. D. A. T.

—It is impossible to give the exact brake horsepower of a motor by making calculations from formulas based upon bore, stroke and r.p.m. The reason for this is that the manifold design, valve size and general structure of the motor, has so much to do with the matter that the power must be

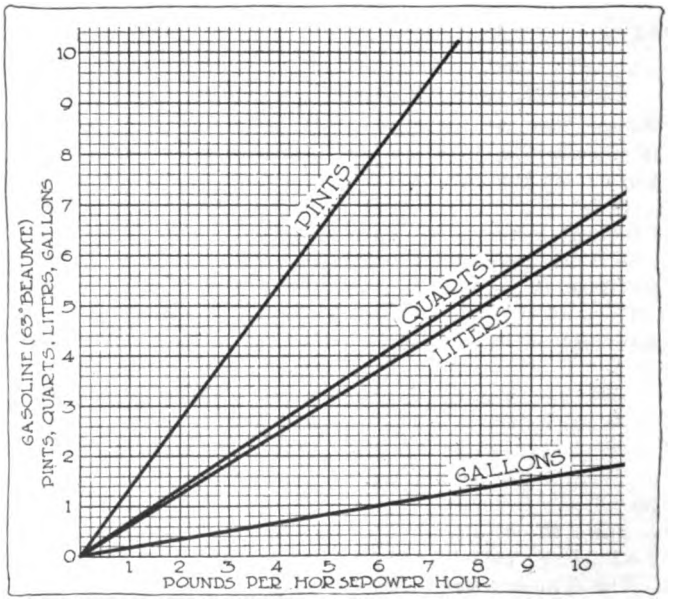

Fig. 3—Chart showing the weight of 63 Baumé gasoline in pounds per horsepower hour

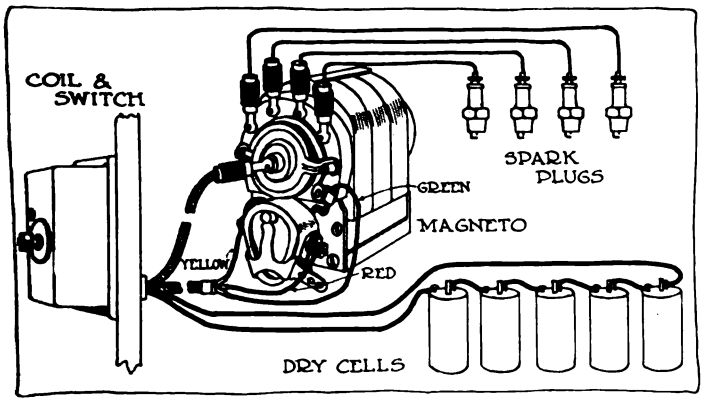

Fig. 4—Diagram of wiring used on model 10 Buick showing terminal connections

measured on a block to get anything like accurate results. An approximation can be made however, by formula, assuming that the motor is in fairly good condition and that the design is approximately correct. On the basis of this formula, your motor would develop about 20 hp.

2—It would be most economical for you to purchase a vertical tube radiator as these are cheaper than the cellular and more rugged. A radiator of about the size of that used in the Ford should be sufficient, and it will be perhaps quite easy for you to pick up a Ford radiator either new or second-hand.

Of course, in tractor work you have not the advantage of the speed of the car which you have in ordinary automobile practice. When running along a road at 25 m.p.h. the current of air striking a radiator has such a large cooling effect that a radiator of smaller size can be used and would be necessary if the car were running in such a manner that it did not get the benefit of this blast of air. It may be well possible therefore, that with a motor which is not designed to secure the best cooling efficiency, that a radiator of this size will be too small, although it would seem that ordinarily it would suffice. The question of radiator size is not one which can be determined by formula but is more in the nature of experimental work. Where a radiator of definite size has been tried out on a given motor with good results, it is natural to suppose that on other motors of the same size the same radiating capacity will do the work properly, and it is on this basis that most radiators are determined.

Piston Rings for Whiting Roadster

Editor THE AUTOMOBILE:—What are the piston ring dimensions of the model A, Whiting roadster, which was made by the Flint Wagon Works Co. of Flint, Mich.?

2—Would a worn cam and breaker arm on Remy magneto cause missing and hitting? Is it O. K. while running slowly?

3—Is model D Schebler carbureter suitable for this motor?

Fort Wayne, Ind. J. E. D.

—The piston ring dimensions on the Whiting roadster are 3¼ in. in diameter and 0.187 in. in thickness.

2—The worn cam and breaker arm would cause the trouble you refer to.

3—Model D Schebler can be fitted to this car, the proper size to use being 1 in.

Missing Due to Loose Terminals

Editor THE AUTOMOBILE:—Please give me a wiring diagram of the Model 10 Buick, and give causes and remedy for magneto missing or back firing at low speeds. The car runs excellently on dry cells, but very poorly on the magneto at low speed.

Meadville, Pa. I. H. A.

—A diagram of the model 10 wiring is shown in the accompanying illustration, Fig. 4. Missing is due, of course, to loose terminals and connections, dirty or burned contact points in the circuit breaker, or poor contact of the distributer brush with its terminals. The Buick company advises that the user should keep the magneto clean.

Back firing is not due to magneto trouble unless the spark is very badly out of time. It is generally due to running with too rich or too lean a mixture from the carbureter.

Wiring of Battery Lighting System

Editor THE AUTOMOBILE:—Kindly give me the best diagram for wiring electric lights on an automobile using a storage battery only but including a meter for two headlights, two side lights, one tail and one dash light with three separate switches.

Newark, N. J. L. S. H.

—The accompanying diagram, Fig. 5, shows the method for wiring electric lights from a storage battery. From your inquiry it is not clear whether you wish to operate all the lamps independent of one another, or to run them in sets as is customary. That is, it is generally the practice to have the two headlights in parallel on one switch with the side and tail lights on another. A third point on the switch turns on both sets, with the dash light independent, so that it can be turned on or off as desired. This gives you independent switching arrangement without the complication of an independent switch for each arrangement of lights. It is hardly possible that you will desire to burn one headlight at a time but since you are using the storage battery it might be that you will desire to economize in this direction and probably the best arrangement in that case would be to simply have an independent switch to break the circuit to one of the head lamps during the time that you desire to operate on but one.

Another means of effecting economy in the current consumption is to have the side lamps off when the headlights are on. You will rarely if ever require both, because the side lamps are merely for the purpose of running signal lights with the illumination feature secondary. The tail light you will need continuously while running or while the car is standing at night.

To sum up, the conditions which you will probably require with the battery as the only source of current are as follows: 1—Side and tail lights lit for car standing, or running through cities where headlights are barred. 2—Head and tail lights lit for country work; 3—One head and tail light lit for running through country with good roads. The accompanying wiring diagram gives the method for accomplishing these conditions and at the same time provides an ammeter to measure the current consumption under any condition. The dash lamp is so placed that it can be turned on occasionally to see the dash instruments and to test the tail light with which it is in series.

Analysis and Valuation of Motor Fuels 14 Methods for Examining Them

From German Data

WHILE the number and diversity of motor fuels made, sold and used for automobile and boat purposes in Germany are much greater than in the United States, the results of the work done for a series of years by Dr. Karl Dieterich in examining all these fuels, with a view to determining their relative utility and value and enabling the public to distinguish among them, will also here be found of interest and valuable for reference, so much more as Dr. Dieterich adds to his competence as a chemist, being a director of the Helfenberg Chemical Works Corporation, that of an enthusiastic automobilist who has owned and driven nearly thirty different cars. He has lately advocated the plan of buying a new car or two every year on the ground that the pleasure is increased, the worries reduced and that the expense of it can be very moderate if the cars are treated right and the opportunities for trading the used cars at a good price are quietly watched with the aid of organized professional salesmanship. But, it may be said, other contributors to the German automobile press vigorously deny that this "American plan" can be made economical for persons in ordinary circumstances, though it may be possible to make it less extravagant than it generally is.

Dr. Dieterich reports his work in *Automobil-Rundschau* for May, where it occupies the whole issue, comprising thirty text pages, and the report is also published as a separate print by the *Mitteleuropaisches Motorwagen Verein* (Central European Automobile Association). An extract is presented in the following, giving the reasoning, statements and chemical information of widest technical and trade interest.

(The German term *Benzin* is throughout rendered as "gasoline," but the word *Gasolin* or *Gasoline* is used in Germany as a trade name for certain grades.)

Many Varieties—Insufficiently Labeled

The fuel for internal combustion motors was formerly only one substance called gasoline whose chemical and physical properties varied but little, but nowadays a large number of fluids are in the market, some of which appear under fantastic names and with claims of incredible fuel virtues. In most cases there is only question of mixtures of gasoline and benzol, of benzol and alcohol, occasionally with additions of kerosene, and they all, of course, have certain advantages, but on the whole they are never superior to the good unmixed gasolines for ordinary automobile motors. The admixture of nitrogen compounds is on account of the great increase of the explosive violence and the danger of backfiring not to be undertaken except with the greatest caution. During the examinations extending over a number of years, nitro-admixtures have been encountered very rarely but camphor and naphthalene with some frequency.

We have advanced so far with modern carbureters that we do not depend absolutely on gasoline but can make use of almost any fuel whose properties we know, if we acquire the experience and insight enabling us to adapt ourselves to the circumstances. The skilful motorist can drive with benzol and alcohol, and if the motor is sometimes found injured through the use of such fuels this result can generally be traced to unsuspected adulterations. It is necessary to have the mixtures so nearly pure and definite in their properties that nothing impossible is asked of the carbureter. Not only a chemical examination of motor fuels is therefore needed but certain criteria should be established for recognizing the properties of every fuel in the market. Under the present circumstances the automobilist or employer of motor power cannot be expected to find his way among the many grades and mixtures that are offered him, and the chemist who undertakes to analyze them looks in vain for systematic guidance in the technical literature. [The author gives a list of all important German books and articles dealing with the fuels and a digest of the contents of each of them.]

Many believe that after the war is over and gasoline again becomes available German automobilists will refuse to return to this fuel, having learned to get along without it, but it is to be remembered that there is a superior convenience in the use of gasoline. The motor can be started easily, even in winter, with the gasoline, and it can be obtained everywhere, while with benzol and especially with alcohol mixtures a marked drop in the temperature necessitates some re-arrangement of the carbureter with adjustment of the pre-heating and of jets. The chauffeur usually prefers the less exacting gasoline and influences his employer in this direction. A quite general return to the gasoline is therefore to be expected after the war, habits and convenience being strong factors, though it is to be hoped that benzol will become a stronger and stronger competitor. Meanwhile the enormous demand for motor fuels and the resulting price fluctuations have changed the market conditions radically. While formerly the standard article was a fairly pure gasoline with the boiling points close together and scarcely any components that did not evaporate at 100 deg. C. and was sold for less than 30 Pfennig (7½ cents) per kilogram, the fluid obtainable at this price now is a gasoline of medium specific gravity, impure, containing benzol, with boiling points far apart and with 20 to 30 per cent of components which do not evaporate below 100 deg. C. At the same time the carbureters have been adapted to the lower grades of fuel. In some of them, which are intended to work with impure medium and heavy gasoline, with benzols and even with alcohol, no other changes are needed for going from a volatile to a heavier fuel than adjustments of air intakes and jets, increased pre-heating and raising of the float level. In other carbureters even these changes can be dispensed with if maximum fuel economy is not demanded. At a pinch the modern carbureter thus consumes anything, even if it cannot digest it.

Specific Gravity No Criterion

Commerce in gasoline and benzol has so far been based on confidence, as they have been sold almost exclusively on a basis of specific gravity, although it is possible to produce any specific gravity of the middle range by suitable mixing of higher and lower fractions of the distillation. The result is usually one of the mixtures, before referred to, in which boiling points are far apart and a large percentage of the components does not vaporize till above 100 deg. C. This development has now made the testing of the motor fuels a necessity; also a separation between gasolines which are adapted for motors and those which are not. It has become desirable to establish physico-chemical specifications for the fuels and to discontinue the practice of grading them by their specific gravity alone.

Comparison of Gasoline and Benzol for Motors

	GASOLINE	BENZOL
Origin	**Distilled from Petroleum**	**Distilled from Coal**
Production and refining	By repeated fractional distillation, supplemented, if necessary, by washing with acids and alkalis.	Mostly from the gases of coke furnaces; also from light coal tar oil. Refined by repeated distillation and leaching with acids, lye and water. Can be made synthetically from benzoic acid or acetylene.
Chemical composition	Unstable mixture of hydrocarbons of the paraffine group: butane C_4H_{10}, pentane C_5H_{12}, hexane C_6H_{14}, heptane C_7H_{16}, octane C_8H_{18}. Principal component is hexane. Boiling point, 69 deg. C.	Almost constant mixture of aromatic hydrocarbons. Pure benzo has 95% C_6H_6; commercial automobile 90% benzol consists of 84% benzol, 13% toluol, 3% xylol and traces of thiophene It is called "90%" because 90% should evaporate up to 100 deg. C.
Chemical formula and specification.	In the main C_6H_{14}; further C_4H_{10}, C_5H_{12}, C_7H_{16}, C_8H_{18}. A paraffine hydrocarbon with open C-chain, indifferent to acids and alkalis.	In the main C_6H_6; in addition C_6H_5 (CH_3), C_6H_4 $(CH_3)_2$ and C_4H_4S. Aromatic hydrocarbon with closed C-chain. Nitric acid and sulphuric acid, mixed, changes benzol to nitrobenzo
Carbon and hydrogen contents	About 85% C and 15% H.	About 92% C and 8% H.
Specific gravity	From .680 (light) to .750 and higher (heavy), at 15 deg. C.	Pure benzol .8730 to .8770 at 15 deg. C. Automobile benzo about .880 at 15 deg. C.
Boiling points	Hexane 69 deg. C. (pentane 36 deg. C., heptane 98.4 deg. C., octane 125.5 deg. C.). Light gasoline (from .650 to .700 s.g.) between 40 and 100 deg. C.; medium from .700 to .730 s.g.) between 45 and 140 deg. C.	Pure 80 to 81 deg. C. Automobile about 80 to 120 deg. C Toluol, 111 deg. C. Xylol, 138 to 141.9 deg. C.
Heat units (calories)	9,500 to 10,500.	9,350 to 10,000.
Freezing point	Below 15 deg. C. minus.	Pure at 0 deg. C.; automobile benzol at 5 deg. C. minus. Mixture of ⅔ benzol and ⅓ gasoline at about 10 deg. C. minus Auto-benzol is doctored with additional toluol for winter use to lower the freezing point.
Velocity of flame propagation in explosive mixture.	2.5 meters per second (oxyhydric gas 100 times as fast).	Smaller than for gasoline.
Air required for combustion	For 1 kilogram 11.7 cubic meters of air, the latter composed of ⅘ nitrogen and ⅕ oxygen.	For 1 kilogram 10.2 cubic meters of air. In practice 20% more air is used.
Combustion formula	$C_6H_{14}+19O=6CO_2+7\ H_2O$; or hexane + oxygen = carbon dioxide + water.	$C_6H_6+15O=6\ CO_2+3\ H_2O$; or benzol + oxygen = carbon dioxide + water.
Fuel efficiency	With economical motor 20 to 23%. Rest goes into heat and intermediate combustion products, as only a smaller portion is completely oxidized.	Similar to gasoline. Benzol is less sensitive to correctness of air mixture than gasoline.
Effective horsepower from 35 hp. Bussing motor, by official tests.	At 1500 r.p.m.: medium gasoline, 54 hp.; heavy gasoline, 53.6 hp.	Only 49.4 hp.; 8% less than with gasoline.
Weight capacity of fuel tank for 100 liters.	70 kilograms.	86.5 kilograms; giving greater mileage from one filling of tank than gasoline.
Vaporization	Easier with gasoline. Most modern carbureters can work with either gasoline or benzol.	More difficult; requires therefor in practice more air as well as more heat.
Odor and exhaust	Almost odorless. Exhaust acid and irritating to mucous membranes.	Aromatic. Exhaust also aromatic; at all events pleasanter odor than from gasoline.
Toxicity	Gases poisonous; caution needed.	Unrefined more poisonous, auto-benzol not more poisonous; caution needed.
Fire risk	Considerable.	Less risk as less volatile.
Corrodes machine parts?	No.	No. If it does, the carbureter is not properly adjusted. Sooting and oily deposits are symptoms of irrational carburization or unsuitable carbureter.
Price per kilogram (in Germany, 1915).	Light grades more than 50 pfennig; heavy grades cheaper.	Formerly 30 pfennig; now higher.
Sources of supply	America, East India, Japan and Sunda Islands (Sumatra, etc.) produce 40 million tons of petroleum annually. Russia, Galicia, Roumania and Germany less than 13 millions. Dealers everywhere.	Germany produces now 120,000 to 150,000 tons, covering home demand. Sales stations organized, and more to be established.

Chemical analysis alone has, on the other hand, become more or less inadequate and unsafe through the specialization of the fuel preparations, as the methods of analysis prescribed in the technical literature take little or no heed of the demands which should be made in each class of the gasolines and of the other fuels. [There is a clash here in the nomenclature, as the Germans speak of light, medium and heavy *Benzin*, making three classes, while no similar classification of gasolines is recognized in the United States.] Such analysis now requires to be specialized with a view to bringing out the fitness or unfitness of each preparation for its intended purpose, and here the guidance of long and first-hand practical experience with the operation of motors is needed in order to throw the light of practice over the chemical examinations. This means, further, the general adoption of a special apparatus and process, devised under the guidance of all the required special knowledge and motor skill and suitable for being used and applied by ordinary chemists or even by motorists who are laymen in this branch of science. [One of the author's objects is admittedly to present the merits of

his own testing apparatus and of the preparation, called "Dracorubin" paper, which is the practical upshot of his protracted investigations in this field, while also giving exhaustively the technical and practical reasons for the preference accorded them among all appliances for tests of motor fuels.]

The accompanying table giving a comparison of gasoline and benzol in their main physical and chemical features is useful for reference and serves as an introduction to other tables giving complete physico-chemical examination of 92 gasoline, benzol and alcohol products, most of which are intended as fuels for motors, from automobile and aviation motors to Diesel motors, while a few are intended for industrial purposes and illustrate the subject by contrast.

Fourteen Methods of Examination

The methods by which each of these products has been examined and classified comprise: (1) determination of the specific gravity, (2) noting of colors and other exterior characteristics, (3) test of odor on filter paper, (4) noting time required for complete evaporation of given quantity, etc., (5) behavior with litmus, (6) coloration with sulphuric acid, (7) qualitative and quantitative tracing of aromatic hydro-carbons and unsaturated combinations, (8) test for benzol with isatine ($C_8H_5NO_2$) sulphuric acid, (9) test for benzol by nitration with nitric and sulphuric acids, (10) test with "Dracorubin," (11) test with nitrate of silver, (12) test for water with calcium carbide, (13) fractional distillation and (14) determination of refractometer degree.

[Dr. Dieterich now gives an account of the process with each of these methods and of the observations made in connection with each of them, finally coming to his conclusions with regard to the best classification of motor fuels, the demands which should be made in each class and the safeguards which should be established in commerce to enable purchasers to know what they are buying and how that which they buy may be utilized to best advantage. Reversing this order, his conclusions are here given first, while the tables of examination data for each of the ninety-two products are omitted. The descriptive account of the examination methods follows in part and will be finished in another instalment.]

Regulation of Motor Fuel Commerce

Above all it is asked that every gasoline shall be sold under one of three classes: Class A, light motor gasolines (*Motoren Leichtbenzine*), class B, medium motor gasolines (*Motoren Mittelbenzine*) and class C, heavy motor gasolines (*Motoren Schwerbenzine* or *Nutzbenzine*). These terms should correspond to definite characteristics, so that the class name alone will tell the motorist approximately the quality of the brand.

Steps in this direction have been taken by different automobile associations, by the commissary department of the army and by municipal bodies, in so far as they purchase gasoline according to specifications, relating especially to the boiling point limits, and the proposition is therefore not altogether new.

The details of the demands to be made are worked out in the following schedules, in which all the required classifications of benzols and alcohol mixtures are also indicated, and which refer to the results which should be obtained by the above-mentioned different test methods.

I. Motor Gasolines

Class A: Light Motor Gasolines

Specific Gravity: 0.650 to 0.700

Primary Properties—colorless, leaving no odor after evaporation, perfectly free from dirt, leaving no grease spot.

Time for Evaporation (of given quantity under given conditions)—less than two hours.

Reaction with Sulphuric Acid—almost colorless, at most a faintly yellow coloration of the acid.

Nitration Test—as nearly free from benzol as possible, at most a faint odor of nitrobenzol.

"Dracorubin" Test—the gasoline colorless, at most a faint rose pink sheen, traces of benzol, at no events more than 5 per cent.

Nitrate of Silver Test—perfectly negative.

Carbide Test for Water—perfectly negative.

Litmus Test—perfectly neutral.

Boiling Points—as close together as possible, lower limit 40 deg. C., upper limit 125 deg. C.

Components Above 100 Deg. C—preferably none, at most 10 per cent.

Refractometer Degree—not under 54. [Explained in the next instalment.]

Price: highest of any motor gasolines, at present fluctuating (in Germany) between 46 and 55 pfennig per kilogram.

Class B: Medium Motor Gasolines

Specific Gravity: 0.701 to 0.730

Primary Properties—colorless, no odor after evaporation, perfectly free from dirt, leaving no grease spot.

Time for Evaporation—not over 2½ hours.

Reaction with Sulphuric Acid—at most faint yellow coloration of the acid.

Nitration Test—almost free from benzol, small amounts of nitrobenzol admissible.

"Dracorubin" Test—gasoline nearly colorless, at most faint rose pink coloration; small natural benzol content, at most 20 per cent admissible.

Nitrate of Silver Test—at most a faint coloration.

Carbide Test for Water—perfectly negative.

Litmus Test—perfectly neutral.

Boiling Points—lower limit 45 deg. C., upper limit 140 deg. C.

Components Above 100 Deg. C.—at most 30 per cent.

Refractometer Degree—not under 53.

Price—lower than Class A; at present between 35 and 45 pfennig per kilogram.

Class C: Heavy Motor Gasolines

Specific Gravity: 0.731 to 0.750 and higher

Primary Properties—as colorless as possible, leaving as little odor and grease after evaporation as possible; yellowish coloration, some odor and residue admissible.

Time for Evaporation—preferably not more than three to four hours.

Reaction with Sulphuric Acid—from yellow to light brown coloration of the acid admissible.

Nitration Test—certain amounts of nitrobenzol or nitrotoluol admissible, showing a natural content (not an admixture) of aromatic hydrocarbons.

"Dracorubin" Test—gasoline rose pink to light red or yellow-brownish coloration; not over 25 per cent of aromatic hydrocarbons (benzol, toluol, etc.) admissible.

Nitrate of Silver Test—faint blacking admissible.

Carbide Test for Water—perfectly negative.

Litmus Test—perfectly neutral.

Boiling Points—lower limit 65 deg. C., upper limit 150 to 170 deg. C.

Components Above 100 Deg. C.—as many below as possible, not more than 75 to 80 per cent above.

Refractometer Degree—not under 50.

Price—lowest of all motor gasolines, at present usually below 30 to 35 pfennig per kilogram.

II. Motor Benzols

Specific Gravity: 0.880 to 0.885

Primary Properties—as colorless as possible, at most faintly yellowish, leaving no odor after evaporation, no residue.

Time for Evaporation—preferably not over 3½ hours.

Reaction with Sulphuric Acid—weak yellow coloration of the acid admissible.

"Dracorubin" Test—dark blood red color = 90 per cent benzol, the test paper after drying tile red, finely mottled.

Nitrate of Silver Test—blackened.

Carbide Test for Water—perfectly negative.

Litmus Test—perfectly neutral.

Boiling Points—lower limit 80 deg. C., upper limit 120 deg. C.

Components Vaporizing Below 100 Deg. C.—at least 90 per cent, the rest passing before 120 deg. C. is reached.

Refractometer Degree—37 to 38.

Price—at present 32 to 37 pfennig per kilogram.

III. Motor Alcohols

Specific Gravity: 0.822 to 0.825

Primary Properties—almost colorless, faintly yellow, odor according to denaturing agent (pyridine).

Time for Evaporation—at most 4½ to 5 hours.

"Dracorubin" Test—dark blood red color = 95 per cent alcohol, test paper after drying not mottled, bright rose pink.

Boiling Points—lower limit below 70 deg. C., upper limit 85 deg. C.

Components Vaporizing Below 100 Deg. C.—100 per cent.

Carbide Test for Water—only small air bubbles and traces of acetylene.

Refractometer Degree—58 to 59.

Price—at present about 35 pfennig per kilogram.

In drawing these requirements for the five classes of motor fuels, it has been considered that carbureters are being improved all the time and that therefore the demands should be formulated a little milder than the actual conditions of the moment would justify.

The brief references to the different testing methods which are not sufficiently explained in the schedules are made clear in the detailed account of each method, the first part of which follows herewith.

1. To Determine the Specific Gravity

Specific gravity is determined either with Mohr's scales or by aerometer at 15 deg. C. For the gasolines a corrective test is advisable, and that devised by Mendelejef has been used. It is described in HOLDE'S *Untersuchung der Kohlenwasserstoffe, Oele und Fette*, 4th edition, page 55.

The medium gasolines now most used, which are those ranging only from .715 to .730, show such wide differences in composition and value that for this reason alone the customary classification by specific gravity without mention of other test results becomes worthless. This classification must therefore be used merely as a convenient basis giving the rough division lines, and within each class each fuel must be judged individually by other indications and with its purpose and price in mind.

The proposed classification by specific gravity is given in the foregoing schedules. Mixtures of gasoline and benzol or of benzol and alcohol have their specific gravity determined by the proportions of their components.

2. Color and Other External Characteristics

After shaking the fluid one pours some of it into a high vessel of clear glass and observes it, using a sheet of white paper as background. In the case of gasolines, if they are colorless, it is not possible to tell what class they belong to. Only the very heavy gasolines and impure benzols and alcohols show a yellowish tint. And it must of course be demanded of all the fuels that they shall be clear; that is, that they shall not contain particles of dirt.

3. Test for Odor on Filter Paper

A little of the fluid is poured out on filter paper and is evaporated. The characteristic odors of gasoline and of benzol can be recognized. The easier and more rapidly a gasoline or benzol evaporates, without leaving any odor or grease spot on the filter paper, the better it is. The odor disappears slowly after a mixed or highly composite gasoline. Impurities remain altogether, and poor gasolines of class B leave a permanent odor and sometimes, as also in the case of most of the gasolines of class C, a greasy residue. Denatured alcohol leaves a white residue smelling of wood alcohol and pyridine. Fluid containing water leaves beads or drops of water.

4. Timing of Evaporation in Clock Crystal

An evaporation pan shaped as the crystal of a clock (the edges rising at a right angle, not flaringly as a saucer), 10 centimeters (4 in.) in diameter and 1 centimeter deep, is placed on a piece of black paper, for easier observation, in a place that is free from drafts and where the temperature can be maintained between 15 and 20 deg. C., and is filled with 10 cubic centimeters of the fluid to be examined. The observation relates to the time required for complete evaporation, to the uniformity—whether it evaporates more rapidly at first and later more slowly—and to the residuum, which may be odorous, oily, white or of other nature.

This test is not commonly employed and has the disadvantage that it is not always easy to maintain an equable temperature without drafts in a room, but this difficulty corresponds somewhat to the working conditions of a carbureter, and the test gives a practical picture of fuel quality which is not so readily obtained by other means by laymen. The average time limits which must be required of the different classes of fuels is given in the schedules.

An observation in connection with this test is that mixtures of light and heavy gasolines as well as poor gasolines in general show a tendency to the formation of drops, but no safe inferences can perhaps be drawn from this peculiarity.

A guide to the proportions in which admixtures affect the time of evaporation of gasolines is given in the following list, in which it will be noticed that the time for pure gasoline is only 57 min., while the schedule of requirements for light gasolines of class A allows "less than 2 hr."

TIME FOR EVAPORATION OF 10 CUBIC CENTIMETERS OF FUEL IN VESSEL OF 10 CENTIMETER DIAMETER AND 1 CENTIMETER DEEP

Pure gasoline						57	min.
"	"	+ 5%	benzol		1 hr.		
"	"	+ 10%	"		1 "	7	"
"	"	+ 20%	"		1 "	26	"
"	"	+ 25%	"		1 "	46	"
"	"	+ 30%	"		1 "	51	"
"	"	+ 40%	"		1 "	54	"
"	"	+ 50%	"		1 "	56	"
"	"	+ 60%	"		1 "	58	"
"	"	+ 70%	"		1 "	59	"
"	"	+ 80%	"		2 "	3	"
"	"	+ 90%	"		2 "	19	"
Ether						38	"
Benzol 100%					2 "	23	"
Toluol					9 "	15	"

Xylol—after 3 days not yet evaporated.

Motor alcohol 95%.....4½ to 5 hr.

As the time and the uniform progress of the evaporation, from beginning to end, means a great deal for indicating whether the fuel is liable to clog a carbureter nozzle and for the functioning and responsiveness of the carbureter in general, and the test shows marked differences in the evaporation time of the gasolines in class C, and less pronounced but still important ones in classes A and B, its practical utility may be considered established.

It shows a number of interesting peculiarities in the retarding and disproportionate effects of heavy components.

(*To be continued*)

ACCESSORIES

Midgley Non-Skid Tire

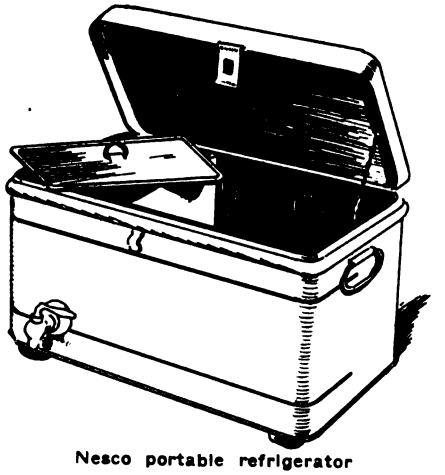
THE Midgley tire secures its non-skid quality by steel wires embedded in the tread. These wires are in the shape of spiral springs made of steel piano wire. As shown by the section herewith, there are four of these spirals, each long enough to completely encircle the wheel. They are vulcanized into the rubber, with their outer surfaces just at the surface of the tread. After running a few miles the wear against the road cuts the exposed edge of the wire, cutting the spring in such a way that the wire is no longer in a spiral, but consists of a great number of wire loops shaped like horseshoes, with the ends appearing just even with the surface of the rubber. The idea is that when the tire comes in contact with the road the rubber is pressed back and the points project, gripping the road like claws.

This action of the wire is secured until the tire is worn down completely past the bottom of the wire loops. According to the manufacturers of the tire, the non-skid quality will be maintained for 6,000 miles, and besides being proof against skid are also of such a nature as to reduce the chances of puncture, eliminate the possibility of stone bruise and protect the side walls against blow-out.—Midgley Tire & Rubber Co., Lancaster, Ohio.

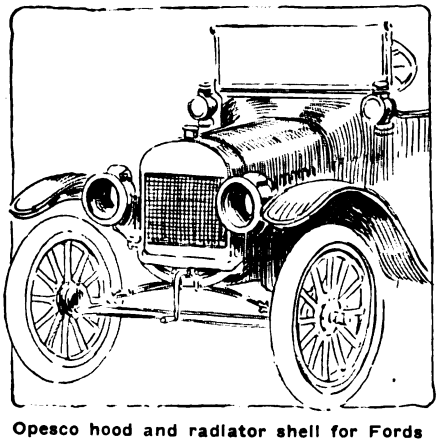
Midgley non-skid tire in section

Nesco Portable Refrigerator

Very often the automobilist desires to carry with him a quantity of fresh food for a trip where a picnic lunch is indulged in. In order to keep the food on such a trip fresh and cool, the Nesco refrigerator has been brought out especially designed for the purpose. It is contained in a convenient size metal case with side handles so that the entire outfit can readily be moved from one place to another. The measurements of the box are 17¼ by 12 by 10½ in. and the outfit includes a granite enamel water cooler with a nickel-plated faucet which screws into the cooler making cleaning easy. The box is made with rounded corners as shown herewith and is made in two styles, either japanned oak or japanned white. The list price either style is $50 per doz.—National Enamelling & Stamping Co., Milwaukee, Wis.



Nesco portable refrigerator



Opesco hood and radiator shell for Fords

Ospeco Hood for Fords

A new hood and radiator shell for Fords under the name of Ospeco is being manufactured which not only gives a new style of hood line but also alters the outward appearance of the radiator, effecting considerable change in the appearance of the whole front of the car. The equipment has a shell which fits over the radiator and the whole is rigidly attached by means of a hood ledge which is part of the outfit and is fastened to the dashboard. The lower part is held by the regular Ford radiator fasteners. The hood is of heavy steel finished in two coats of baked enamel. The radiator shell may be finished in nickel, if desired. Price, $15.—The Ouchie Specialty Co., Detroit, Mich.

Positive Split Rim Tire Remover

A positive tire remover is designed to take the tire from split rims in a short time without prying, hammering, or running any danger of injuring the casing or rim. Many difficulties have been encountered in the moving of detachable rims from casings, and it has always been a difficult task where the casing showed any tendency to stick. The subsequent hammering has often damaged rims to such an extent as to make them practically useless.

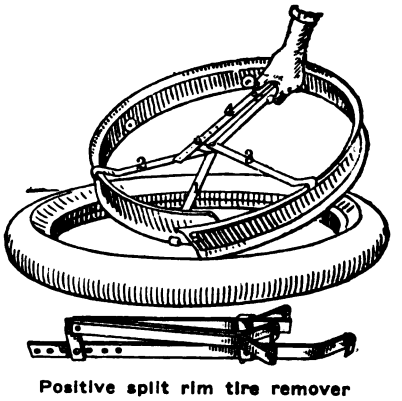
With the positive remover the rim is drawn together evenly and sprung out of line. It can be folded up to fit in the tool kit of the car and can be adjusted to fit any size rim. Its weight is 3 lb., and it is sold for $2.—Positive Supply Co., Davenport, Iowa.

So-Luminum Aluminum Solder

The latest aluminum solder evolved is called So-Luminum which is designed to render possible perfect soldering of broken aluminum parts without recourse to welding. The new preparation is too hard and strong to permit of using a soldering iron, though the metal runs at a very low temperature and tins quickly. A gasoline torch is the only thing that is necessary and the So-Luminum is claimed never to break at the soldered point while there is no oxidization. Lost bits of aluminum can be replaced by building up and are said to be found harder than the original under the hammer test. So-Luminum is claimed to take the place of welding and to do the work in one-fourth the time at one-fourth the cost.—So-Luminum Mfg. & Engineering Co., New York City.

High Power Magnet Charger

In order to permit car owners to do their own charging of magnets for magnetos, a simple device has been desired for some time. The new high-power magneto charger is designed to fit the needs of either the repairman or private owner,



Positive split rim tire remover

and is a compact instrument which can be readily operated by any one. The charging box is compact, of light weight and simply operated. The horseshoe magnet is removed from the magneto, placed against the opposite poles in the charging box and then pressed down into the box where the coils are located. The current is then switched on and off and the magnet is charged. The outfit sells for $15 complete.—C. C. McDonald Electric Co., Chenoa, Ill.

Topping Jack

Since the advent of the automobile there has been a demand for safe, efficient and easy-working jacks. The Topping jack, built on the same principle as a locomotive jack, that is, operating by means of a screw, has recently been introduced with these features.

The special feature of the jack is the screw, which produces a rise at both ends, the jack therefore working twice as fast. No appreciable increase in effort is required to operate it. On the center of the screw is fitted a bevel gear which meshes with a bevel pinion, this pinion being actuated by a ratchet into the socket of which the handle is fitted.

On the upper end of the jack is a right-hand thread which engages with the traveling lifting head and the left-hand thread on the lower end with the standard. Both the head and standard are inclosed in a protecting case or shell, out of which they emerge as the jack is operated. The jack is reversed by throwing over a small pin located at the base of the handle socket. Another feature is that the swivel top is removable and can be replaced by another swivel top having a side spur for low set axles as shown in the accompanying illustration.

The passenger car jack, which has a rise of 7 in., costs $6.50 with an extra charge of 50 cents for the side lift. The truck jack with a similar rise costs $8.50. —Topping Bros., 122 Chambers Street, New York City.

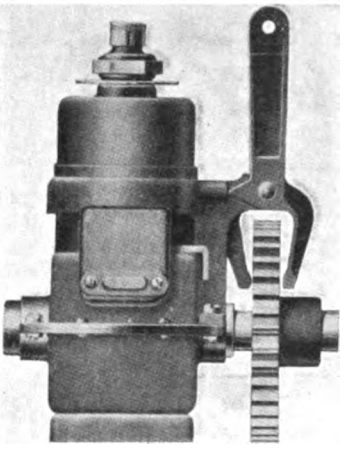
Stevens Products

Breaking off a cylinder-head or water-connection bolt in the hole is often a serious matter to the owner of a Ford car, because of the difficulty of getting out the stub and keeping the threads clean and intact. The work is easily done, however, with a Stevens set which includes a drill of the proper size to drill out the bolt, leaving only a small amount of metal in the threads; a bushing which goes in the clearing hole in the cylinder head to guide the drill—solving what is perhaps the most difficult part of the problem; and a tap to clean out the threads ready for the insertion of a new bolt. The set is inclosed in a neat case and sells for $1.

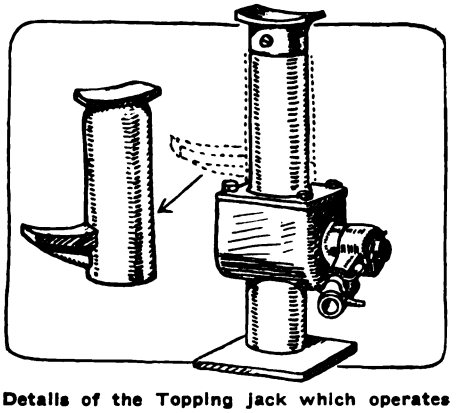
Another product of the company is a gasoline valve for Ford cars which is arranged to stop the supply of fuel to the motor and so warn the driver when there is 1 gal. left; turning the valve to the emergency position permits this gallon to be used. Another position of the handle shuts off the supply altogether, locking the car. The device is screwed into the tank and the indicating dial and the handle are attached to the heelboard. The valve can be installed by the owner. Price, $1.

To help keep in the driver's mind the Safety First idea the Stevens concern has placed on the market a neat radiator emblem, consisting of a radiator cap surmounted by a plate bearing the words "Safety First" in white letters on a green ground—the official colors of the "Safety First" Society. The emblem is adapted to any car. It sells at 75 cents. —Stevens & Co., New York City.

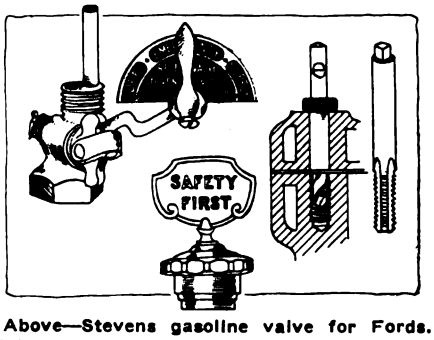
McDonald high-power magnet charger



Improved Stewart single-cylinder tire pump



Details of the Topping jack which operates on the screw principle



Above—Stevens gasoline valve for Fords. Right—Drill, bushing and tap for removing sheared bolts. Bottom—Safety radiator emblem

Stewart Tire Pump

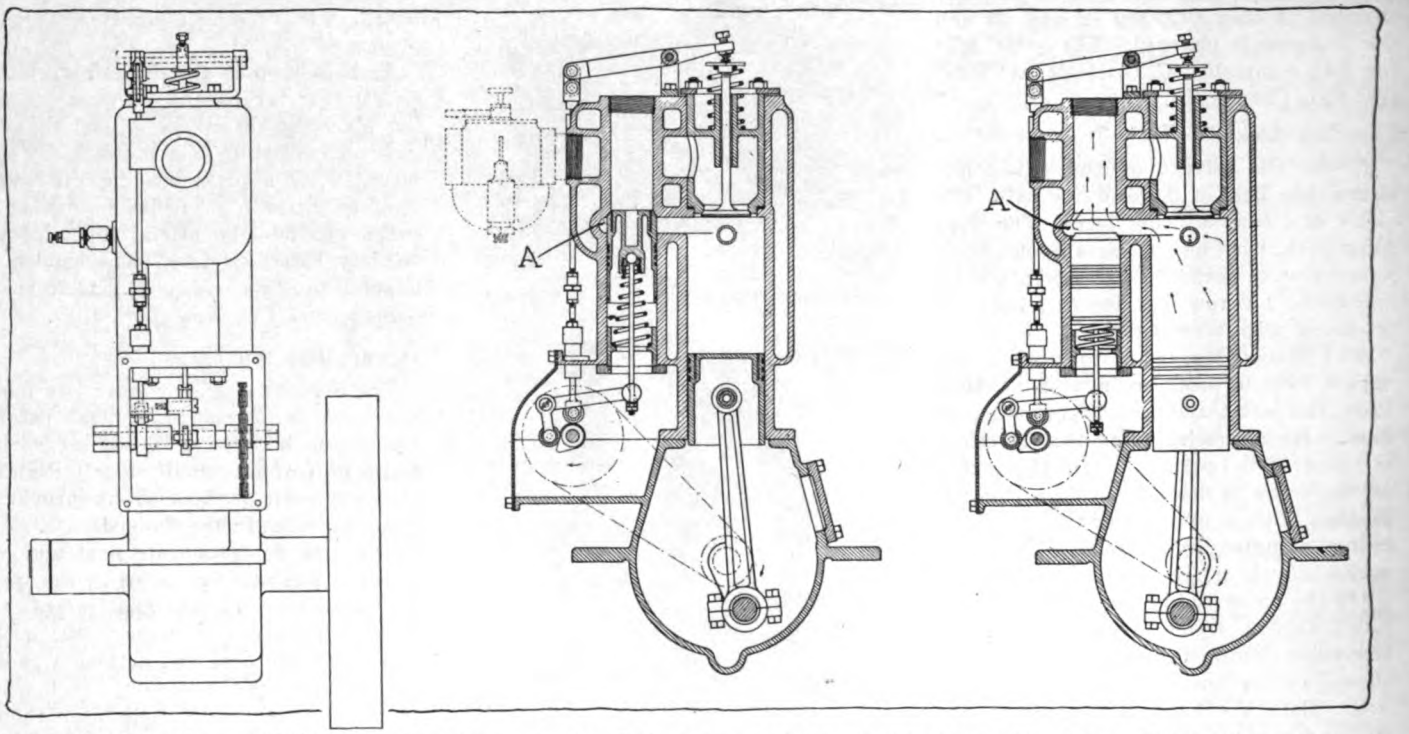
The Stewart single-cylinder tire pump has been improved in several details. The piston is fitted with one large ring and a unit of five small rings. Rigidity of attachment is insured by providing four bolt holes in the flanged base. The shifter arm is a separate part and can be set at any angle required by the space available for the installation of the pump. A brass coil connects the outlet valve with the hose and acts as a radiator, preventing the sending of hot air to the tire in case the operator should neglect lubrication for a long period. The pump is furnished complete with attachments for attaching to any standard car on the market. Price, $15.—Stewart-Warner Speedometer Corp., Chicago, Ill.

Titan Bronze for Manufacture

A new metal which is designed to take the place of brass castings, and also to cheapen the cost of manufacture, for certain purposes, has been brought out in the form of a bronze known as Titan. The new metal has a tensile strength, according to its manufacturers, of from 75,000 to 85,000 lb., and an elastic limit of 40,000 to 48,000 lb. The reduction of area is said to be from 45 to 50 per cent and elongation 22 to 30 per cent, thus enabling its use in many places where steel has been used but where bronze would have been preferable. The advantage over steel is said to be principally in its corrosion-resisting qualities. The metal can be worked hot and where the reduction in manufacturing cost enters, is due to the use of a method by which the gear makers can cast it in sand or iron hills and then press it into a die of correct size. This gives a process with many of the advantages of die casting principally in that the machining costs for finishing are avoided. The main uses of the new metal are given as for drop-forgings, hot-rolled thread bolts, screws, gears, pinions, etc.—Alpha Metals Co., Bellefonte, Pa.

Medanich Motor Has Balanced Exhaust

Semi-Automatic Exhaust Valve and Unusually Large Intake



Left—Side view of one-cylinder Medanich motor. Center—End section, showing exhaust valve close. Right—Exhaust valve open. A is the cylinder pocket which permits the gases to pass around the valve, balancing it and preventing it from sticking

A MOTOR which is featured by the possession of a balanced exhaust valve and an unusually large intake valve and port area, has been brought out by the Medanich Motors Co., Inc., Louisville, Ky. This concern was recently incorporated in that State with a capital stock of $125,000 subscribed by local capitalists and has had since the early part of March a single-cylinder motor in daily operation driving a 3½-hp. generator at the plant of a local concern devoted to experimental work.

The illustration herewith shows a section of the motor with exhaust valve in closed and open position. The manner in which the exhaust valve springs clear of the operating mechanism, when the force of the exhausting gases gets beneath the seat and above the valve, is also shown. This and the unusual construction and type of valve and port shapes and arrangements make up the features of the new design.

Will Work on Kerosene

As will be seen from the illustration, the intake valve is an overhead poppet which is only noticeable from its unusual size and the size of the cage containing it. The intake passes from the side-outlet carbureter illustrated, around the cored exhaust passage and directly into the chamber above the valve. The passing of the exhaust ports directly through the intake passage preheats the mixture, and it is one of the claims of the inventor of this motor that, due to this heat, it will operate on kerosene with the usual type of carbureter.

The semi-circular, cylinder pocket A, in the upper portion of the exhaust valve chamber permits the mixture under compression and the burning gases during explosion to pass entirely around the exhaust valve, thus permitting it to balance itself and preventing it from sticking against the cylinder wall. When the exhaust valve is open, any pressure in the cylinder tends to force the valve back upon its springs, compressing same. This is done whenever the exhaust cam touches its bell crank with sufficient force to pull the valve down a minute fraction of an inch and break the seal of the valve seat. When this is done, the force of the out-rushing exhaust gases forces the valve downward against the spring. The cam is so arranged that the valve will not close when the cylinder pressure falls before the pressure of the spring, but will be held open by it until the cylinder is completely scavenged.

It is stated that the cylinder pocket surrounding the exhaust valve at *A* is so small that the economy of operation is not affected. Carbonization of this balancing port is also stated to be avoided by the thorough scavenging which takes place at each exhaust stroke.

The unusually large size of the intake valve and its cage will be noted from the section. With this arrangement the proportion of valve diameter to cylinder diameter is 2 to 3, thus a cylinder of 3-in. bore would have an intake and exhaust valve 2 in. in diameter. The manner of driving this valve is shown clearly, the cam acting directly upon a roller follower and thence to a vertical pushrod with a cross bell crank lever at the top. Throughout, the entire design is intended to provide a motor which will be capable of high rotative speeds.

Begin Work on Massachusetts Roads

BOSTON, MASS., July 20—Work has commenced upon the Massachusetts small town roads, and highways are under construction in about 350 places. Before the work is ended $900,000 will be spent, not including the $2,500,000 provided for the western part of the State. The commission has about $750,000 for State highways and about $600,000 has been allotted to some fifty cities and towns.

Wanted, Better Detail

THE characteristic of the 1916 automobiles which so far have been announced that is most conspicuous is better motors. Having adopted the high-speed type, the American engineer has developed it to a high pitch with great rapidity, and he has good reason to fear no competitor when high-power efficiency is the point at issue. This is a fine thing to be able to say, and the men responsible are greatly to be congratulated, but in thus expressing belief in the very real nature of the progress made, attention may be drawn to other opportunities for engineering skill to show itself.

Most automobiles, whether good or medium in quality, develop many small noises when they have done over 5,000 miles. The universals sometimes rattle a trifle, the brake rods work loose, the control becomes a little less precise, and the motor may be even better than it was when new, but the chassis certainly deteriorates in detail from the first time it goes on the road.

For years we were satisfied with crude motors, but we shall never be again. So with the petty detail. Once it is improved by painstaking thought and careful experiment, the user will soon look for and expect the perfection of small detail which makes for continued, complete satisfaction. With soundless motors the least little chinking noise in the chassis becomes irritating to the average man and maddening to the mechanically hyper-sensitive. To remove these noises and to make the chassis easier to look after at the same time needs about one-thousandth part of the attenion that the motor has received. The work when done is not of a showy order, but the owner of the car will notice it soon enough when he starts his second season's driving.

A Chance for Spring Makers

IN several of the leading British automobile journals lately there have been comments and correspondence on the subject of springs, doubtless because the normally fine roads of the United Kingdom are badly cut up by heavy military traffic. While opinions differ a good deal in detail, there stands out as a prominent fact the idea that American cars are better sprung than European.

Against the opinion thus expressed we find criticism that the rear springs are often too free on American chassis and that shock absorbers are necessary to obtain the best effect. However, when it is remembered that the springs which go to Europe on American cars are designed to suit rough dirt roads primarily, and therefore are not fully suitable for a better class of surface, one is forced to the conclusion that the American spring must be very good indeed. At the moment the British and Continental motor car factories are not producing automobiles in any quantity except where they are making for the war departments, which means that the demand for parts to suit normal designs of cars is small. But directly after the war, when the factories get once again into full swing, should be a golden opportunity for the American spring makers to secure a permanent footing.

In order to supply the best sort of spring to suit European roads it would be necessary to study conditions on the spot; both of road and of chassis, but this should not be difficult. Any time during the next six months would seem to be particularly opportune for a visit to Europe by a few of our leading spring designers and there is good reason to think that this has been widely appreciated.

S. A. E. Assistance

WAR is a destroyer, the greatest destroyer of equipment in existence. Such destruction means replacing. The cheapest and easiest replacement is that accomplished when standardization is highest. It would be difficult to imagine any condition where standardization in army or navy work could be carried too far.

Because of this standardization aspect, the invitation of Secretary Daniels of the navy to the Society of Automobile Engineers, asking that it select two members for the Navy Advisory Board is most opportune, as we know of no other engineering society better qualified to give advice on this all-important work of standardization. Perhaps S. A. E. members are not so familiar with navy requirements as with army requirements, but the rudiments and elements of standardization are the same and the experience of the S. A. E. will be a most valuable asset to the board.

S. A. E. Issues New Data Sheets

Includes Information on New Standards and Reference Tables for Drafting Work

NEW YORK CITY, July 27—Members of the Automobile Engineers have been supplied with a number of additional data sheets for the S. A. E. loose-leaf handbook. These comprise in all seventy-two new data sheets, thirty-five being for Volume 1 and thirty-seven for Volume 2. Among the data sheets are those giving details of the most recently adopted standards of the Society putting at the disposal of draftsmen in the designing rooms of the different factories the standard dimensions which are of such value in the design of many parts of the car and its equipment. In fact, the supplying of the draftsmen with these dimensions is the practical cashing in on the long period of work done by the Standards Committee up to that time.

The new standards, now in data sheet form, include those on yoke and rod and pin dimensions, large hex spark plug shell, large diameter thread pitches, standard sizes of pneumatic tires, recommended practice for pleasure car frames, side outlet carbureter flanges, large sized flared tube ells and tees and the new specifications for ground return electrical installations on gasoline cars.

Horsepower Tables Extended

In addition, the table of horsepower values derived from the N. A. C. C. (formerly A. L. A. M.) formula has been extended to cover eight- and twelve-cylinder engines. Conversion tables of percentage of grade to angle of grade are also included. Piston displacement tables for eight- and twelve-cylinder engines of from 137.4 to 1531.5 cu. in. content are given. Two sheets are devoted to crank angles and corresponding piston positions. The effect of altitude on horsepower development of gasoline engines is treated on three sheets, with curves and formula. Diametrical and circular pitch tables, which are useful to engineers in laying out transmissions and other gear work, are given on four sheets. To the metric conversion data previously issued there has been added a table giving decimals of a millimeter for each thousandth of an inch. It is believed that this is the first time this information has been distributed generally.

Linear Units Table

The new table of standard linear units should be found very beneficial, as well as the conversion curve of miles per gallon to liters per 100 kilometers, enabling the engineer to judge intelligently of gasoline consumption performance expressed in terms of the metric system. The sheets on the standardization of pipe thread gages, total keyway depth, equivalent values of electrical, mechanical and heat units and the economical selection of belts and pulleys, make the Handbook of greater value.

Simultaneously with the distribution of the new sheets, a revised index was issued containing exhaustive cross references in order that all data in the Handbook, which is now constituted of over 400 pages bound in two loose-leaf folders, can be located in a minimum of time The members of the Society are furnished with a complete index for insertion in each volume of the Handbook.

As new standards now before the Society for mail ballot are adopted, additional data sheets will be issued. The Society also collects and prepares for publication other data than its adopted standards when the former are of direct interest to the automobile engineer and manufacturer, proper credit being given to the original sources.

The S. A. E. Handbook is one of the most valuable products of the Society. In addition to the official version of newly adopted and firmly established automobile engineering standards, it contains more data necessary in the automobile drafting room than are obtainable in any other one publication. It is the most important and useful of the handbooks in the engineering library of the technical man engaged in the automobile and allied industries.

Owen Leaves Chalmers to Become Saxon Vice-President

DETROIT, MICH., July 23—Percy Owen, general sales manager of the Chalmers Motor Co. has resigned to become vice-president of the Saxon Motor Co. where he will have entire charge of sales. Mr. Owen was one of the nine original organizers of the Saxon Motor Co. and still holds his original stock interest.

It is with the consent of Hugh Chalmers, president of the Chalmers Motor Co. that Mr. Owen goes to the Saxon. The agreement was reached some time ago, but Mr. Chalmers was unwilling for the actual change to take place until it could be arranged without impairment of the efficiency of his own organization.

Mr. Owen came to the Chalmers Motor Co. being at first eastern district sales manager. Then he came to the factory and after a short time was appointed sales manager, which position he held until June 1, when he was given the title of general sales manager. Before joining the Chalmers organization Mr. Owen was sales manager for the Carl H. Page Co., New York distributors for the Chalmers. Previous to that he was one of the pioneer importers.

Ford Reduces Car Prices $50

Effective Aug. 1—Possible Rebate for Coming Year To Be Decided Later

DETROIT, MICH., July 28—Beginning with Aug. 1 the Ford touring car will be sold at $440, and the roadster at $390. This is a reduction of $50 on each model as compared with the existing price during the past year.

Aug. 1 marks the opening of the fiscal year of the Ford Motor Co., and the company announces that no rebate is to be given persons buying Ford cars during August, September and October, but that it is possible a rebate will be decided upon later when the exact cost of manufacture, etc., which cannot be determined for several months, has been calculated. It is claimed that the roadster will be produced in much greater quantities than during the past year.

Canadian Ford Reduces Parts

FORD, ONT., July 26—The Ford Motor Co. of Canada, Ltd., has reduced the price on all spare parts for Ford cars by about 10 per cent. This means a saving from the former quotations of about $60 for a complete touring car.

Stearns Cuts Four $355

CLEVELAND, OHIO, July 24—A price cut of $355 is the announcement of the F. B. Stearns Co. on the light four Knight car which last year sold for $1,750 but which now sells, with the reduction, at $1,395.

At this lowered price the company offers practically the same car as for the 1915 season but with improvements in body design and added mechanical refinements. The body refinements are not radical but merely detail changes to bring the appearance of the car up to the latest dictates of body fashion. Mechanically, the car is practically unchanged except for the addition of the Westinghouse lighting and starting system.

Crown Co. Incorporated

KALAMAZOO, MICH., July 27—The Crown Automobile Mfg. Co. has been incorporated, its capital stock being $50,000. This is the new concern which recently purchased part of the former Michigan Buggy Co. plant to make a low priced four-cylinder car. The incorporators of the new company are: D. H. and W. B. Smith, Toledo, Ohio; Jas. H. Johnson, South Haven, Mich.; C. E. Kracht, Des Moines, Iowa; T. H. Walbridge, Toledo, Ohio; Ida Cadwallader, Fostoria, Ohio; J. B. Shifflet, Cleveland.

Trade Review of the Week

New England Busy—Northwest Slows Up—Sales in Central South Improving

NEW YORK CITY, July 28—The last week has shown no indication of a let-down in the amount of business done by Detroit and Indianapolis automobile and parts makers.

In Detroit nearly all of the factories are working at capacity and many of them are greatly behind in orders.

Behind in Shipments

Packard expects to ship its twelves to dealers in August, and begin shipments to customers in September. One-third of the Cadillac dealers were at the factory this week and reported conditions good in their territories. The 1916 Cadillac shipments will start the first of next week. Dodge is oversold. Hupp is behind with shipping orders; and Studebaker, Paige, Maxwell, Saxon and Hudson report the past week a busy one.

Parts and accessory makers report increased business the same as automobile builders. The demand is indicated by rapid strides in addition to plants and equipment. Among the concerns on which building operations are being pushed ahead are, Continental, Timken, Lycoming, and such car makers as Chalmers, Paige, Dodge, Hudson and Ford.

Indianapolis Demand

From Indianapolis are reports of continued demand from all parts of the country during the week. Marmon is working full force and its difficulty is getting materials to meet the demand. National says that the demand is double the supply. Pathfinder closed one of the most successful weeks in its career, one order alone calling for 600 cars. Stutz is moving along at its regular rate of 1500 cars a year production. Cole is concentrating its efforts on Southern business.

Minneapolis Slows Up

Reports from leading distributing centers such as Boston, Cincinnati, Minneapolis and Los Angeles show generally increased demands for cars.

In Minneapolis the expected slackup in sales at this season has begun to be felt by Twin City distributing houses. Dealers are burdened with orders they cannot fill. Field men from the territory report that the harvest has begun and farmers are not buying; they are too busy. A big business is expected in the fall, the outlook for the small grain crop being heavy. The only backward crop is corn. Many dealers throughout the territory report prospects holding back in placing orders until several 1916 cars not yet announced are brought out. Radical price reductions are creating considerable disturbance with many buyers who purchased before the reduction. This fact is holding back buying as some anticipate further cuts. There is no market for used cars, price reductions in 1916 models having destroyed the market.

The Cincinnati territory which includes a good part of Ohio, Kentucky, Indiana and West Virginia reports business from 50 to 300 per cent ahead of a year ago. Maxwell business is double that of last year; Saxon is 300 per cent better; Studebaker 30 per cent better; Overland 100 per cent better, and so it goes with many of the more popular priced makes. Ford sold 200 cars in the last week as compared with 350 in the entire month a year ago. In the field of higher-priced cars, the demand is stationary except in one or two unusual cases. Locomobile reports a little better and so it is with Marmon, White, Pierce, and others. Winton business increased considerably the last week as compared with the preceding three weeks. Stutz and Mitchell report good business.

New England Awake

Conditions in New England have taken a surprising change for the better during the past ten days, warm weather and more settled buying conditions as a result of the blowing over of the announcement of new cars at heavy price reductions have generally improved the buying conditions. Immediate deliveries are wanted and it is apparent that manufacturers making 1916 announcements and who cannot make deliveries are losing sales. All of the New England distributors report similar conditions. Many Overland dealers have offered to increase their orders if they could obtain early deliveries. Maxwell signed more orders before the new sixteen was shown than they had taken a year ago, and 24 hours after the car was exhibited it would have been possible to have had 500 sales for immediate delivery had the cars been obtainable. Studebaker would require 1000 cars to meet its immediate demands and dealers are going direct to the factory with the hope of getting quicker deliveries. Briscoe and Inter-State has had two big weeks, business being 50 per cent greater than in the entire preceding month. Buick is vastly behind in deliveries.

In the truck field improved conditions are noticeable. Autocar reports that while July is ordinarily a quiet month, business is holding up well. Mack and Saurer are making steady deliveries. Some of the other truck makers are not pushing the local market because of apparent heavy war orders which they are filling.

A New Six for $1,000

$750,000 Sun Motor Car Co. Enters Field—Secures Factory in Buffalo

BUFFALO, N. Y., July 27—The Sun Motor Car Co., has been incorporated with a capital stock of $750,000 to manufacture a six-cylinder car to list at $1,000 or less. The James silk mill property located in Buffalo and Lackawanna at the junction of the Buffalo, Rochester & Pittsburgh Railroad with parkway has been secured, the Sun company purchasing the entire property which embraces 4 acres. The Sun company will immediately occupy one story of this building which covers 17,000 sq. ft. In addition 6 acres of land adjoining this property has been purchased, and contracts for a new factory 600 by 150 ft. let. The new factory will be of reinforced concrete construction, is to be completed in 90 days and will employ 500 men.

The Sun Motor Car Co. has as its leading spirit R. Crawford, until recently sales manager of the Haynes Automobile Co., and also associated with him is R. C. Hoffman from the same concern. Mr. Crawford conceived the plan for a small six a year ago, and later organized the Automobile Engineering Co., an Illinois corporation, for the purpose of designing and building experimental cars.

The Sun six is fitted with a high-speed motor claimed to develop 55 hp. The company plans to build 2000 of these in the twelve months following the completion of the factory.

Already a selling organization has been developed and distribution will be largely confined to such centers as New York, Chicago, Boston, Philadelphia, Pittsburgh, Cleveland, Buffalo, Detroit, Cincinnati, Indianapolis, St. Louis, Kansas City, New Orleans, Minneapolis, Milwaukee, Omaha, Denver, Salt Lake City, San Francisco, Los Angeles, Dallas and Atlanta.

No Changes in Chalmers Co.

DETROIT, MICH., July 27—At to-day's annual meeting of the Board of Directors of the Chalmers Motor Co. no changes were made in the personnel of the company. Hugh Chalmers remains president, which thus quiets the recent rumors that he was to retire from the company. The other officials are: Lee E. Olwell, general manager; C. C. Hinkley, chief engineer; C. A. Pfeffer, secretary and assistant general manager; S. H. Humphrey, vice-president and works manager; C. A. Woodruff, purchasing agent.

Truck and Passenger Car Exports Gain $7,570,770 Over May, 1914

Trucks Jump from 99, Worth $127,024 in May, 1914, to 2426, Valued at $6,583,912 for This Year— Passenger Car Increase Is 1664, Worth $1,113,882

WASHINGTON, D. C., July 24—Details of the exports of motor cars during May and the 11 months of the fiscal year ending May, together with figures for comparative periods, just made public by the Department of Commerce, are of widespread interest. The figures show that the exports of commercial cars increased from ninety-nine, valued at $127,024, in May, 1914, to 2426, valued at $6,583,912, while during the 11 months' period these exports rose from 694, valued at $1,061,354, in 1914, to the tremendous number of 11,006, valued at $30,561,880 in 1915. The astounding increase in the exports of commercial cars since the outbreak of the European war has called attention anew to the wonderful productive capacity of the United States.

Passenger Cars Gain

The exports of passenger cars in May last amounted to 4821, valued at $3,971,483, as against 3157, valued at $2,857,601, exported in May a year ago. During the 11 months' period these exports declined from 26,324 cars, valued at $23,522,981, in 1914, to 19,462 cars, valued at $16,327,955, in 1915.

The exports of parts, not including engines and tires, increased in value from $600,793, in May, 1914, to $789,826, in May last, and from $6,150,264 to $6,714,001 during the 11 months' period.

Exports of motor car tires likewis show a healthy growth, the exports show ing a gain from $368,745, in May a yea ago, to $671,757, in May last, and fro $3,052,089 to $4,224,408, during the 1 months' period.

United Kingdom Best Customer

The United Kingdom still leads a nations in the importation of America motor cars. During May the exports cars to that nation amounted to 40 machines, valued at $5,895,856, while May a year ago the number was 663 a the value $556,753. During the months' period the exports rose fr 6982, valued at $5,613,853, in 1914, 11,688, valued at $16,736,165, in 1915.

France's Contribution

France's contribution to the mot car manufacturers of the United Stat in May last was $1,106,572 for 521 n chines. The exports to that country May a year ago amounted to 275 ca valued at $146,785. During the months' period the exports to France

creased from 1286 cars, valued at $835,256, in 1914, to 4472 cars, valued at $11,142,414 in 1915.

Under the heading "other Europe," the figures show that the exports of cars increased from 445, valued at $356,091 in May, 1914, to 699 cars valued at $1,638,709, in May last. The 11 months' period shows an increase from 2686 cars, valued at $2,133,917, in 1914, to 2817 cars, valued at $7,768,101. Truck exports undoubtedly helped to swell the total for the 11 months of 1915.

Germany failed to import any American-made cars in May last, but in May a year ago 206 machines, valued at $162,552 were shipped there. During the 11 months' period Germany imported 1391 cars from this country in 1914, the value of which was $1,003,000, while during the same period of this year the number was twenty and the value $20,164.

Italy is the only other European nation that figures in the export returns and the figures show that only twenty-three cars were shipped there in May, the value being $17,004. In May a year ago the number was thirty-three and the value $25,846, while during the 11 months' period the number decreased from 326, valued at $228,894, in 1914, to 111, valued at $75,372 in 1915.

During May a year ago Canada imported 764 cars from the United States, the value being $941,345 and this number was increased to 838 in May last, although the value dropped to $630,990. A decline is also noticed in the 11 months' figures, the number in 1914 being 4111, valued at $5,277,752, while in 1915 the number was 3606 and the value $3,796,729.

West Indies and Bermuda

Surprising gains are shown in the exports to the West Indies and Bermuda. In May, 1914, there were thirty-four cars, valued at $31,374, shipped to those countries, while in May last the number had increased to 262 and the value to $131,779. During the 11 months' period the number increased from 491, valued at $468,467, in 1914, to 1383, valued at $827,989, in 1915.

Exports to South America show a decline from 180 cars, valued at $169,107, in May, 1914, to 165 cars, valued at $88,631, while during the 11 months' period the exports decreased from 1909 cars, valued at $1,888,529, in 1914, to 1071, valued at $583,119, in 1915.

During May, 1914, there were shipped from this country to British Oceania 466 cars, valued at $416,259. In May last the number had fallen to 256 and the value to $212,316, while during the 11 months' period the exports fell from 3819 cars, valued at $3,325,902, in 1914, to 2727 cars, valued at $2,271,349, in 1915.

Two hundred and forty-one cars were shipped to Asia and other Oceania in May last, the value being $588,116, while in May a year ago the number was only 118 and the value $124,910. During the 11 months' period the exports were 1993 cars, valued at $1,927,157, in 1914, and 1581 cars, valued at $2,708,004, in 1915.

"Other countries" imported from the United States in May last a total of 203 cars, valued at $241,015, while in May a year ago the number was sixty-eight and the value $50,002. For the 11 months' period the exports were 1860 cars, valued at $1,628,610, in 1914, and 925 cars, valued at $892,362, in 1915.

Chalmers Opens Suggestion Contest

DETROIT, MICH., July 23—The Chalmers Motor Co. has promoted a suggestion contest which is open to every one of its employees, except officials, and will close Dec. 24. The winner will receive $100. There are two prizes of $50 each, five of $20, twenty of $5, twenty of $2.50 and fifty of $1.00.

The intention of president Hugh Chalmers in inaugurating such a contest is to have every member of the Chalmers force try and find something which will bring about or will lead to some improvement no matter in what department of the plant and no matter whether it applies to head or hand work, to shop work or office work. It may concern improvements in machinery, how to increase sales, how to reduce mailing or transportation cost, precautionary health and fire measures, advertising ideas, reduction in costs in any department, substitution of machinery for manual labor, etc.

Suggestions from heads of departments, superintendents, foremen, engineers, designers and inventors relating to other work than their own will also be considered.

—

Two S. A. E. Men for Advisory Board for United States Defense

NEW YORK CITY, July 24—Considerable interest is felt by members of the Society of Automobile Engineers because of the fact that Secretary of the Navy Daniels has requested the organization to designate two representatives to serve on the Advisory Board, of which Thomas A. Edison will be chairman, as announced some time ago. The Council of the Society has the matter of selecting the two members of the Committee before it and has asked for suggestions from the Governing Committees of the Society sections.

Kuqua Visits Southern States

INDIANAPOLIS, IND., July 24—S. J. Kuqua, vice-president of the Cole Motor Car Co., is making an extended trip through the Southern States investigating business conditions.

No Tires on Cars for Export

—

British Gov't Concerned Over Violations of Rubber Guarantee by a Few Makers

NEW YORK CITY, July 27—The British government has recently warned the Rubber Club of America in this city that it is greatly concerned over the violation of the rubber guarantee by a few car manufacturers who persist in shipping automobiles fitted with rubber tires to neutral countries, this shipping of cars with tires being a violation of the guarantee. According to the guarantee, tires can be shipped only to neutral countries such as Spain, Portugal, Greece, Holland, Norway, Sweden and Denmark by way of the United Kingdom, and by licenses obtained from the British War Trade Department in London.

Up to the present the agreement between the British government and the individual rubber manufacturers in America has worked out most satisfactorily and America is getting all of the crude rubber she wants, in fact the imports are in excess of a year ago. The present guarantee arrangements by which the British government permits rubber to be shipped to American makers dates to the end of January and up to the present time approximately 30,000 tons of plantation rubber coming from the Federated Malay States and Ceylon have been received. Since the opening of the war not a pound of rubber has been lost due to destruction of vessels carrying it and the price is remaining steady.

The present guarantee arrangements permit of all rubber manufacturers who sign the guarantee obtaining practically all the rubber they require, this rubber being consigned to the British Consul General in New York and only handed over to the importers with the necessary guarantee, the Rubber Club of America taking care of the necessary clerical work in connection with all imported rubber. Under the present arrangements motor cars shipped to the neutral countries mentioned must not be equipped with rubber tires, but the tires must be shipped separately by way of London, the matter resting with London whether the tires eventually reach their destination or not.

At a hearing last week before the Federal Trade Commission in Detroit, which was attended by many representatives from factories building automobiles and parts, the government was urged to take some action to bring about relief to American makers owing to the present rubber situation, this applying particularly to rubber export troubles.

Accessory Makers Can Join N. A. A. J.

Jobbers' Assn. Provides for Associate Membership—To Fight Mail Order Houses

CHICAGO, ILL., July 21—After a two-day session, the first mid-summer meeting of the newly-formed National Association of Accessory Jobbers, closed here to-day after more than 100 representatives of the accessory business, including makers and jobbers, discussed the evils now existing in their business. The first day's meeting was for members of the executive committee only but on the second day two open meetings were held and it was during one of these that a most important move was made to change the by-laws so as to provide for an associate membership to which accessory manufacturers are eligible. This caused many of those manufacturers present to sign application blanks for membership, thus making the association one containing makers and jobbers.

Fight Mail Order Houses

In the open meeting of to-day there were taken up a number of subjects which are of vital importance to everyone in the legitimate accessory business. Heading this list comes the recommendation that the Association start a campaign against manufacturers offering standard goods to mail order houses and leagues who list them in their catalogs at cut prices.

Dead Accounts Loss

It was pointed out by a number of members present that there is a tremendous yearly loss in the accessory business due to dead accounts, so it was recommended that a credit bureau be established to assist members in avoiding bad accounts and in making collections of those which were taken and are unpaid. W. K. Norris, of the McQuay-Norris Co., piston ring maker of St. Louis, Mo., brought to light some methods used by the dealers of St. Louis. He stated that in his city 10 per cent of the car owners buying accessories are "dead beats," which means that each one has beaten more than two firms. When a man refuses to pay one firm he still is in a position to purchase of another, but when two concerns have unpaid bills against a man that man cannot get credit in any member's house. The recommendation of establishing a credit bureau to assist the members of the N. A. A. J. was left over to be discussed at the next meeting in October.

One of the most difficult tasks the association must cope with is the defining of jobber and dealer, so it was deemed advisable to appoint a committee of ten consisting of five jobbers and five accessory manufacturers to formulate a list of jobbers, to be presented at the next meeting.

Other subjects discussed were: Reversed telephone charges and how this evil may be eliminated, so as to make it equally fair for dealer, jobber and maker. Parcel post shipments it was ordered should be sent with a lump charge for carriage and insurance. Uniform terms have been adopted and these are not to exceed 2 per cent cash, ten days, thirty days net. A standing committee of three was appointed to be known as the railroad committee and that this should handle all matters relating to rates, freight shipments and similar matters.

Return Goods Evil

The return goods evil was another taken under consideration and it was ordered that when a bill is correctly filled by the jobber no credit will be allowed for return goods unless a full explanation has been made and the consent of the association obtained and with this done, a charge of 10 per cent will be made for service and shipping expenses and the credited amount for the goods will be based on the prevailing price when the goods are returned.

Fees Reduced

The initiation fee has been reduced from $500 to $100 and the annual dues not to exceed $300 which are to be paid in the form of assessments. The manufacturers taken as associate members are to pay $100 yearly dues and no initiation fee.

The following jobbers were present at the meeting to-day: Julius Andræ & Co., Milwaukee, Wis.; Automobile Supply Co., Detroit, Mich.; Fred Campbell, St. Louis, Mo.; Electric Appliance Co., Chicago, Ill.; Philip Gross Hardware Co., Milwaukee, Wis.; Herring Motor Co., Des Moines, Iowa; Weinstock-Nichols Co., San Francisco, Cal.; Motor & Machinists Supply Co., Kansas City, Mo.; Excelsior General Supplies Co., Chicago, Ill.; Nebraska Buick Auto Co., Lincoln, Neb.; Nichols, Dean & Gregg, St. Paul, Minn.; Weinstock-Nichols Co., Los Angeles, Cal.; Kansas City Automobile Supply Co., Kansas City Mo.; Minneapolis Iron Store Co., Minneapolis, Minn.; Motor Car Supply Co., Chicago, Ill.; Reinhard Brothers, Minneapolis, Minn.; General Sales Co., Detroit, Mich.; Western Motor Car Supply Co., Minneapolis, Minn.; Gibson Co., Indianapolis, Ind.; Interstate Electric Co., New Orleans, La.; Walkerville Hardware Co., Walkerville, Ont.; Sieg Iron Co., Davenport, Iowa; Weinstock-Nichols Co., Oakland, Cal.; Washington Auto Supply Co., Washington, Ill.

Chicago Fights Fenders for Trucks

Owners, Dealers and Manufacturers Claim They Are Unnecessary Expense

CHICAGO, ILL., July 20—Chicago's truck fender situation bobbed up again to-day, when the reports of the big truck users, truck manufacturers and the local motor trade association, were presented to Chief of Police Healy for consideration. It will be remembered the chief received on July 6 the reports of the three men acting for the city in the testing of these fenders, and because of lack of knowledge of the situation, took the suggestion of one of the local dealers to postpone the meeting for two weeks before making any definite decision.

Fender Makers Organize

To-day's discussion brought no definite results. There were present representatives of such large establishments as Armour & Co., the Consumers Co. and the Chicago Telephone Co. also members of the Chicago Assn. of Commerce and the Chicago Automobile Trade Assn. The makers of the six truck fenders were there and they have themselves formed an association calling it the Fender Manufacturers' Assn.

There were arguments from both forces and a fair judge of the situation does not have to go deeply into technicalities to hand over a decision in favor of the truck users and makers and against the fender makers and others who would have commercial vehicles equipped with costly, unnecessary front fenders.

Pedestrians' Negligence

Perhaps the pro-fender contingent was hit hardest by the words of Russel Huff, consulting engineer for the Packard Motor Car Co., and nominee for president of the Society of Automobile Engineers. Mr. Huff stated in a letter to the Chicago Automobile Trade Assn., which was read at the meeting, that front fenders do not protect, do not save lives and that of all the accidents due to the wheels passing over a body 90 per cent are caused by the rear wheels, and not the front, striking the person. Also that trucks are responsible for less than 50 per cent of the motor vehicle accidents and 10 per cent of these are caused by front-wheel contact. Also that of this 10 per cent the majority of accidents is caused by negligence on the part of the pedestrian.

"Why should Chicago manufacturers and merchants spend more than $2,000,000 for an accessory for motor trucks which does not do that which we would have it do—eliminate the larger number

of accidents? Why should these business men spend a vast amount of money for something which is in its experimental stages?" These were two strong questions asked of those who wish the fenders adopted. The fenders do not protect and this is proved by statistics and if the fenders did protect pedestrians and save lives, then they certainly are desirable.

Practically every representative at the meeting stated that his concern would most willingly buy fenders and pay more than for the present makeshifts, if the fenders would save lives. But the fenders submitted to the city, for application to the front of the truck, do not save lives, as coroners' statistics show, is the contention of one of the men opposed to the adoption of the present contraptions.

As the situation now stands the ordinance provides that commercial cars only be equipped with fenders.

—

ArBenz Has New Four

CHILLICOTHE, OHIO, July 26—The ArBenz Car Co. has placed on the market a new four-cylinder model which is to sell for $675. It is fitted with a 3¼ by 5 block motor with a removable cylinder head which is cooled on the thermo-syphon plan. The transmission elements include a cone clutch, three-speed selected gearset and full floating rear axle. The wheelbase is 108 in., and tires are 30 by 3½. Equipment includes a one-man top, electric horn, Stewart speedometer and electric starting and lighting apparatus.

Menominee Electric at $1,250

MENOMINEE, WIS., July 24—The Menominee Electric Mfg. Co. has completed the first of the electric carbriolets which it intends to manufacture to sell at $1,250, an unusually low price for an electric. The car has a wheelbase of 108 in., is fitted with Exide batteries and Goodyear cord tires. It can be charged for a distance of 50 to 60 miles and is capable of 18 to 20 m.p.h. The car weighs approximately 1800 lb. Doors are wide and the leather top can be let down. The body is painted a royal blue with black hood and back. A charging outfit it furnished with the car by which it is possible to charge the batteries direct from an electric light socket. The company expects to make 150 cars the first year.

—

Maurer Amplex Factory Manager

SOUTH BEND, IND., July 24—LeRoy F. Maurer, formerly chief engineer of the Amplex Mfg. & Machine Co., Mishawaka, Ind., has been appointed factory manager. The company is evolving a valveless two-cycle motor along the lines of the old Simplex, designed by Mr. Maurer.

Olds 8 Will Be Different

—

Appearance Varies from Other Models—120-In. Wheelbase and Delco Electric System

LANSING, MICH., July 26—First details of the new $1,295 eight-cylinder model which has been added by the Olds Motor Works reveal that the car is strikingly different in appearance from other Oldsmobiles. The hood, which covers the conventional V-type motor with cylinders 2⅞ by 4¾ in., is rounded at the top with the radiator in the form of a half ellipse. Side lamps are eliminated and for city driving smaller lamps are mounted on top of the headlamps.

The wheelbase is 120 in., tires being 33 by 4 straight side, and the transmission elements include a cone clutch, three-speed gearset and floating axle with spiral type gears. Engine and gearset are a unit. Springs are semi-elliptic front and three-quarter elliptic rear. Equipment includes Delco lighting, starting and ignition, electric horn, Stewart speedometer and clock.

—

Velie to Sell Direct Through Car Dealers

MOLINE, ILL., July 24—The Velie Motor Vehicle Co., this city, which heretofore has distributed its products largely through the implement dealers which handle products of the John Deere Plow Co., with which the Velie company is closely allied, has altered its policy and henceforth will contract direct with responsible motor car dealers and distributers, eliminating the Deere Plow branches. This change presages no segregation from the John Deere Plow Co. interests insofar as the factory, directors or stockholders are concerned, the manufacturing influence and backing remaining the same.

—

Stutz Adds Two-Passenger Roadster

INDIANAPOLIS, IND., July 22—For all-around work the Stutz Motor Car Co., this city, has brought out a roadster model which is one of the series C designs produced at the present time by this concern. The roadster is a two-passenger car designed for those wishing a comfortable, roomy, easy-riding car of inclosed door type. It is fitted with a slightly lower gear than the Bearcat model and is therefore not as fast, being designed more for all-around use than for high speed. The body is of semi-streamline design with the cowl dash merging into the hood lines providing an attractive appearance. The door hinges are concealed.

The specifications of this car show that it is only manufactured with a four-cylinder motor. The motor dimensions are 4¾ by 5½ and the other important data regarding the chassis features include pressure oiling system; Remy electric lighting and starting; Stutz gearset and rear axle; Timken front axle; semi-elliptic front and rear springs; 34 by 4½ tires and 56-in. tread. The wheelbase of this tire is 120 in., and the price $2,100. If wire wheels are desired a set of five will be furnished for $100. Other than this the equipment is complete, at the purchase price.

—

Reo Adds 3-4-Ton Truck

DETROIT, MICH., July 27—The Reo Motor Truck Co. is bringing out a ¾-ton truck styled Model F which sells at $1,075, completely equipped. The chassis only, less express body, driver's seat, canopy top and windshield, but otherwise completely equipped, lists at $1,000. The truck, which is specially made for grocers, butchers, bakers and department stores, has a wheelbase of 120 in. The inside length of the standard express body is 96 in. and the width 44 in.

A four-cylinder, 4⅛ by 4½, motor cast in pairs provides power. The carbureter is a Johnson and ignition is provided by a Remy generator. The starting and lighting system is also Remy. The clutch is a dry disk type; gearset is selective. Hyatt Roller bearings are used throughout. The rear axle is a floating and Timken bearings are used on the front axle. The artillery wheels have 34 by 4½ pneumatic tires, plain in front and knobby tread on rear. Springs are semi-elliptic. The gasoline tank holds 11 gal., the water tank 3 and the oil tank ¾ gal. included in regular equipment are head, tail and instrument lights, speedometer, ammeter, horn, tools, etc.

—

Carlston Kingston Chief Engineer

KOKOMO, IND., July 23—William S. Carlston, who during the last eight years has been assistant to George Kingston of Byrne, Kingston & Co., manufacturers of Kingston carbureters and mufflers, has been appointed chief engineer. He had charge of the experimental work and was active head of the engineering department during the past six or seven months, owing to the condition of Mr. Kingston's health.

—

Five Armored Trucks a Day

HARRISBURG, PA., July 26—The Motor Truck & Tractor Co., this city, is at present manufacturing five armored trucks daily for the Russian government, these being on a contract for 1400 recently received. Part of the contract has been sublet to the Baldwin Locomotive Works.

1915 Goodrich Profits $4,000,000

First 6 Months Show Gain of $1,348,922 Over First Half of 1914

NEW YORK CITY, July 28—The B. F. Goodrich Co., Akron, Ohio, issued its statement to-day for the first half of 1915 which shows that the net profits for the period amounted to approximately $4,000,000, after making proper allowances for maintenance, depreciation, bad debts and all outstanding liabilities, etc.

This is a very large gain over the corresponding period of 1914 when the net income of the company, after maintenance, depreciation and other charges had been provided for was $2,651,278. In other words the balance in favor of the first half of 1915 is $1,348,922.

Preferred stock to the value of $2,000,000 has been redeemed and canceled by the company out of surplus, leaving $28,000,000 outstanding. Quick assets show a gain over current liabilities of approximately $3,016,866.16 for the period.

The officers of the company have recommended to the board of directors that no dividend be declared on the common stock at this time.

—

No 30% Studebaker Dividends

SOUTH BEND, IND., July 24—Estimates of business done by the Studebaker Corp. that have been rumored about in Chicago and New York have been declared incorrect by A. R. Erskine, president of the corporation in an interview. "Referring to the estimated sales, earnings and financial condition of the Studebaker Corp. for the year 1915 and especially to the fact that the corporation might pay 30 per cent dividends as a result thereof," said Mr. Erskine, "most of the estimates given were highly exaggerated. It is true that the regular business of the corporation in the automobile division is greater than last year, but the vehicle business is running at a considerable reduction in volume. The war orders which amounted to approximately $20,000,000 have practically all been completed and shipped so that while the total business of the first six months shows an increase over last year, that of the next six months is unlikely to equal it and is dependent upon developments which none of us can foresee. The profits of the corporation for the first six months are running at the rate of about 20 per cent per annum and the dividend rate on the common stock is 5 per cent and will continue at that rate in the immediate future. The payment of any such dividend as 30 per cent is entirely out of the question."

—

Steel Prices Higher

NEW YORK CITY, July 27—The heaviest trading is shown in the metal markets. The steel markets for the past week continued an upward tendency in prices on all grades of steel, practically every department of the trade experiencing heavy demand for its products from abroad, structural steel being included in the lists of products sought. The total gain in price is given at $1.50 for both Bessemer and open-hearth steel.

Copper shows a downward trend and very little trading is done, the market being influenced by the severe break in London and the continued lack of buying on this side. As anticipated, the tin market continued to decline yesterday, spot lots being sold at 36 cents against previous sales of 36½ cents. Heavy arrivals and further increases in stocks afloat to this country are expected to keep the market in a weak condition for some time to come. The rest of the markets show very little trading and no increase in demand. Cottonseed oil was exceedingly dull during the session, but in face of the weakness in provisions showed comparative steadiness. The rubber markets were somewhat steadier with no material change in the crude rubber situation.

—

May Increase Paige-Detroit Capital to $1,000,000

DETROIT, MICH., July 22—At a special meeting of the stockholders of the Paige-Detroit Motor Car Co. to be held Aug. 2, it will be proposed to increase the capital stock of the company from $250,000 to $1,000,000. It is expected that at the same meeting a stock dividend of 100 per cent, or thereabouts, will be declared. It is further rumored that half of the increased capital, that is $500,000, will not be issued for the time being but will remain in the treasury.

On Aug. 1 the monthly dividend for July, amounting to 10 per cent, will be paid to stockholders of record July 24. The company's books will be closed from July 24 to Aug. 9. The stock of the Paige-Detroit company is held by eighteen stockholders.

—

Stewart-Warner Earnings Gain $271,000

CHICAGO, ILL., July 26—Stewart-Warner Speedometer Corp. completed its half year on June 30 with an increase in net earnings over the first six months of 1914 of $271,000. In addition to declaring the regular quarterly dividends at the rate of 7 per cent on the preferred and 6 per cent on the common, the directors decided to anticipate the sinking fund requirements on the preferred stock to the extent of setting aside $46,500 in addition to the regular $65,000 for the year, making the total sum devoted to the sinking fund this year $111,500.

—

Dividends Declared

Pyrene Mfg. Co., New York City, 1½ per cent, payable Aug. 2.

YOUNGSTOWN, OHIO, July 26—Republic Rubber Co. quarterly dividend on common stock, payable Aug. 2 to stockholders of record July 20.

—

Kelly-Springfield Wins Old Suit

NEW YORK CITY, July 27—For infringement of the Grant patent on an imbedded-wire solid tire the Diamond Rubber Co. of New York, must pay the Kelly-Springfield Tire Co. $212,376.29. The Federal court has just confirmed the accounting. This marks the end of eighteen years of litigation, since the beginning of which both parties have changed. When the suit was brought Kelly-Springfield was the Consolidated Rubber Tire Co. and the defendant is now a Goodrich property. The patent, No. 554,765, expired Feb. 18, 1913.

The accounting is made up as follows: Damages, $130,391.75; extra award by

Briggs-Detroiter Creditors to Receive $103,000

DETROIT, MICH., July 22—The creditors of three concerns for which the Detroit Trust Co. is trustee, will shortly receive a total of about $103,000, as follows: 10 per cent to the creditors of the Briggs-Detroiter Co., or approximately $40,000; 2 per cent, or about $50,000 to the creditors of the Michigan Buggy Co., this making thus far a total of 22 per cent dividends paid; 4 per cent, or about $13,000 to the creditors of the American Voiturette Co. which makes a total to date of 24 per cent to the latter's creditors.

—

Field Opening in Russia

PETROGRAD, RUSSIA, July 10—The Pobeda Commercial House, this city is announcing that there is a large field in Russia for the sale of automobiles, trucks and motorcycles which will be open as soon as hostilities have ceased. The business formerly done with Germany, it is pointed out, will be transferred to other countries and the United States should get its share. The Pobeda house, whose address is 61 Moika, Petrograd, and whose American agents are Ladenburg, Thalmann & Co., New York City, state their intention of taking the agency of low, medium and high-priced cars at this time.

Tire Stocks Firm in Tone

—

Show Some Gains—Car, Truck Accessory Securities Show Little Change

NEW YORK CITY, July 27—Tire stocks were the only ones on the local automobile securities market to show particularly strong gains during the past week. Comparatively few changes of importance are recorded for any of the other issues, the general tone of the market seeming to tend toward dullness with some of the securities half a point or a point higher than last week, though some of them were lower. Kelly-Springfield common is ten points above last week's level, while its first preferred has gained a point and its preferred five. Miller common rose six points though the preferred is nine points lower than last week. U. S. preferred shows a gain of a point while Swinehart lost two. Goodrich preferred gained a half point and Goodyear common declined a point and the preferred a half point. Portage common added a point.

Of the car stocks, General Motors common is eight and a half points lower and the preferred a point higher than last week. Packard, Studebaker and the Reo stocks are half a point higher. White preferred is four points lower and Willys-Overland common five.

—

Gramm-Bernstein Gets Big Orders

LIMA, OHIO, July 26—The Gramm-Bernstein Co. is shipping trucks at the rate of 125 per month. After accepting an offer for 500 vehicles, the company was compelled to turn down two other orders, one for 200 3-ton machines and the other for 200 2-tonners, owing to lack of production facilities, although the plant is running to capacity and is being quadrupled in size to meet the demand. The company is finding a large market for its product in England and France.

—

A. R. Pardington of L. H. A. Dead

DETROIT, MICH., July 28—A. R. Pardington, vice-president and secretary of the Lincoln Highway Association, of this city, who for the past two years looked after the management of the association, died at Parker Hospital today, where he had been ill for some weeks. For several years Mr. Pardington has suffered with a malignant disease which had seriously handicapped him. Mr. Pardington's associations with the automobile industry have extended over many years. He was instrumental in the building of the Motor Parkway, Long Island, and has long been connected with automobile sports, having refereed all of the 500-mile races on the Indianapolis Speedway.

—

Cole Closes Prosperous Year

INDIANAPOLIS, IND., July 24—At the annual stockholders' meeting of the Cole Motor Car Co. held to-day, the usual cash dividend was declared and a satisfactory amount carried into the surplus account. The company's annual statement shows that the last year has been one of the best in the history of the company.

Match Race Aug. 7 in Chicago

Resta, DePalma and Cooper Take Up Oldfield's Challenge for 100-Mile Contest

CHICAGO, ILL., July 27—As a result of a challenge hurled at Dario Resta and Ralph DePalma last week by Barney Oldfield, the Chicago speedway will be the scene of a 100-mile match race Aug. 7, when four, and perhaps five, of the most noted drivers in the country will meet to settle a much-mooted question of supremacy. Resta already has accepted Oldfield's challenge and Bob Burman and Earl Cooper have challenged the challenger in turn and they will be accommodated by Barney. Ralph DePalma has not been heard from as yet but it is thought that the winner of the 1915 International Sweepstakes is too good a sportsman to decline the issue and that he will participate in the match race.

In his challenge, Burman offered to give Oldfield and Resta a 2-mile handicap if they would permit him to drive his 350-in. Peugeot, but neither would accede to such a request and consequently Burman will drive his 300-in. car. Cooper will be at the wheel of a Stutz and claims the title of America's champion in an American car.

Oldfield will enter the lists at the wheel of the Grand Prix Delage that David G. Joyce, the local sportsman, imported recently from France for Barney's use.

The management of the Chicago speedway has hung up $7,500 for the race, the purse to be divided as the contenders see fit. The contest will be made an annual event and a silver trophy will be awarded the winner. According to the deed of gift, any driver capturing three 100-mile races will come into permanent possession of the challenge cup.

The winner of the Aug. 7 race probably will crowd the 100 miles inside of an hour. The 100-mile record for the Chicago track is 99.08 m.p.h., established by Porporato's Peugeot in the first century of the 500-mile derby of June 26. There were twenty-two cars on the track and he was forced to stop for a tire change before he completed the first 100 miles. It is thought that with only four or five cars on the course, much faster time will be made.

—

Plan Speedway for Dallas

AUSTIN, TEX., July 24—Plans are being laid by a number of the leading automobile men of Texas for the inauguration of a movement to build a first-class speedway at some point in the State. It is probable that Dallas will be decided upon as the location of the new racing course. While the plans for the enterprise have not as yet taken definite shape, it is stated that the Indianapolis speedway will be largely patterned after. A partial canvass of automobile manufacturers and racing men has been made with the view of sounding their sentiment toward the project and it is stated that it promises to meet with universal cordial support. It is expected that public announcement of the preliminary plans will be made soon.

—

Allison Buys Two Peugeot Racers — Aitken in Charge

INDIANAPOLIS, IND., July 26—James A. Allison, secretary-treasurer of the Prest-O-Lite Co., and one of the four owners of the Indianapolis Speedway, has purchased two Peugeot racing cars which are to be raced in American speedway events, the cars in all probability to be entered in the Minneapolis and New York speedway races this fall. John Aitken, well known in racing by his connection with the National cars, will have charge of the two Peugeots which are described as the machines driven by Goux and Boillot in the 1914 French Grand Prix road races. This is the first step taken by the speedway people in the possible solution of the present difficulty of not having enough cars for the present speedway circuit. Mr. Allison during the recent Indianapolis Speedway meet suggested the possible necessity of the different speedways purchasing cars until such time as American makers can build to meet speedway requirements.

—

Two Stutz and Mercer for Elgin

CHICAGO, ILL., July 27—Two Stutz cars with Cooper and Anderson as drivers, have been entered in both races at Elgin. Henning's Mercer has also been entered in Friday's race, so the entries total ten to date.

—

Speedway for Cleveland

CLEVELAND, OHIO, July 23—A 2½-mile speedway is to be built near Cleveland by a company which filed incorporation papers in Columbus recently. The speedway is to cost $700,000. Four hundred acres near the city limits have been acquired. M. L. Yuster, founder of the Yuster Axle Co., is the promoter of the project.

—

Sheepshead Speedway Ticket Office

NEW YORK CITY, July 25—The Sheepshead Bay Speedway Corp., is preparing to open an office for the sale of tickets at 1696 Broadway, this city. The executive offices remain at 17 Battery Place.

Detroit Speedway Hits a Snag

Little Progress Made on Stands or Track—No Race for Labor Day?

DETROIT, MICH., July 26—The Detroit Motor Speedway, which has for several months been in the public eye, by its broadly advertised plans to build a speedway here, and for which it has been selling admission tickets for a Labor Day meet Sept. 6, has made little progress to date and it is almost impossible to have a meet on that date. The track has been advertised as a 2½-mile cement oval, 90 ft. wide. None of the cement has been laid and it would be a physical impossibility to have such a track completed by Labor Day. The erection of grandstands has not yet been started, although it has been stated in publicity that work has been started on the stands to seat 100,000 people. Widespread publicity has been sent out to the effect that the track had received sanction for a Labor Day meet, but this is not true, as the American Automobile Assn. has not granted such sanction.

Up to the present the speedway organization has been expending large efforts in selling stock, and has disposed of $103,330 worth of stock at $10 per share to over 300 small investors in Detroit, this being exclusive of stock sold to the officials of the organization. Holdings run from two shares to 200. Aver $72,000 has been secured in cash by this stock sale and the remainder taken in notes. These figures are based upon a report from the Michigan Sureties Commission, and refer to the original stock issue of $500,000. After the balance of this issue was turned over to the contractor, the stock was increased to $800,000, so that there would be some to sell on the same basis as before but it is understood little of this has found a market.

When asked concerning the situation, S. D. Maddox, general manager and vice-president of the speedway organization, gives his explanation of the matter by saying that any reports circulated have been just publicity. Detroiters began to get skeptical of the speedway advertising and publicity as there were only thirty-six working days in which the track could be completed. Examinations of the speedway property showed that the entire gradings of the turns had not been completed and that there were not 500 men at work as stated. Recently John B. Whelan, president of the Detroit Motor Speedway, when interviewed by THE AUTOMOBILE representative, declared that he had every reason to believe the track would be ready for a

Labor Day meet, but concrete experts state that it would be a physical impossibility to have a cement track ready by that time or for weeks afterward.

The main difficulty with this speedway matter has been the lack of capital. When the present organization took over the work of its promotion, it was expected that Detroit people would respond readily but it was not easy to sell stock, and the work of grading the track proceeded slowly. Some time ago the contractor agreed to take the balance of stock remaining unsold in lieu of cash for his work, thinking that he could dispose of the stock and thus get sufficient funds to complete the work. Things have proven otherwise and to-day the contractor has the stock on his hands, being credited with figures 33,682½ shares worth at par $336,825.

President Whelan declares that in the event of no race money collected on the sale of tickets will be refunded.

—

Practice Begins at Des Moines

DES MOINES, IOWA, July 25—Five thousand people saw Barney Oldfield set new mile course records at the formal opening of the new Des Moines Speedway here to-day. Oldfield negotiated 2 miles in 1:10 1/5, 105 m.p.h. in his front-drive Christy. He went the 5 miles in his Fiat in 3:01 4/5, 100 m.p.h. It was announced that both of the marks are new world's records for a 1-mile course.

Preliminaries for the 300-mile event of Saturday, July 31, will be staged on Wednesday and Thursday of this week. Only the twelve cars making the fastest time will be eligible. Entries are:

Driver	Car
O'Donnell	Duesenberg
Chandler	Duesenberg
Henderson	Duesenberg
De Palma	Stutz
Scott	Anderson
Strunk	White
Mulford	Mulford
Cooper	Sebring
Brown	Du Cheyne
Burman	Peugeot
Jones	Clergy
Donaldson	Emden
Vail	Mulford
Oldfield	Delage
O'Connell	O'Connell

Denver-Cheyenne Record for Cadillac

DENVER, COL., July 24—Harold Brinker, of Cheyenne, Wyo., drove a Cadillac eight from this city to Cheyenne, 112 miles in 2 hr., 17 min. to-day, breaking the previous record of 2 hr., 43 min. Eleven cars started in an unofficial race between these two cities, promoted by the Denver *Post*. Leon Nelson of Denver was second in a Metz, in 2 hr. 53 min.

—

10,450 Cars in Dallas County

DALLAS, TEX., July 24—Dallas County is now said to lead any county in the South for the number of automobiles. The 10,450th number was issued this week.

100-Mile Race for Providence

—

$10,000 Race on Narragansett Park Speedway Sept. 18 for 300-Cu.-In. Cars

PROVIDENCE, R. I., July 24—The Narragansett Park Speedway, Inc., will open its new 1-mile cement track which has been built for automobile and motorcycle racing on Saturday, Sept. 18, when $10,000 in prizes will be offered for a 100-mile race open to cars of 300 cu. in. piston displacement and with a maximum weight not exceeding 2500 lb. Fourteen cars will be permitted to start, according to A. A. A. rules, and these will have to qualify at an average speed of 70 m.p.h. for two laps of the track.

Work on the track is being hurried at present, 100 men being employed, and it is expected that in 2 weeks the track surface will be completed. The surface is special asphalt mixture, resting on a deep layer of rock asphalt. In shape the track is an oval, varying in width from 75 to 81 ft. Inside of this track proper is an asphalt safety apron on which the cars can go in case of accident or if repairs have to be made. This apron is 14 ft. wide. The track is banked throughout its entire length, on the straightaways 4 to 6 per cent and on the curves 10 to 31 per cent.

—

Allentown Race Meet July 31

ALLENTOWN, PA., July 24—A race meet is scheduled for the Allentown Fair race track July 31, when seven events will be run off under the management of the Matty Matthews Racing Association of New York under the sanction of the American Automobile Association.

—

Packard Tests at Indianapolis

INDIANAPOLIS, IND., July 24—J. G. Vincent, vice-president of the Packard Motor Car Co., accompanied by a corps of assistants has been here for the past week experimenting with twin-six models. It is understood that hereafter all Packard experimental work of consequence will be completed on the local speedway.

—

Show at Michigan State Fair

DETROIT, MICH., July 26—At the annual Michigan State Fair which will be held here Sept. 6 to 15, the automobile show will again be a feature. Most of the local automobile dealers have already taken space, it is said, by the fair officials, and like last year the Ford Motor Co. will have a miniature Ford assembling plant in operation.

Among the passenger cars thus far on the list to be shown are: Ford, Dodge King, Haynes, Grant, Reo, Mitchell, Cadillac, Hudson, Studebaker, Buick, Ross, Overland, Oakland, Chandler, Hupmobile, Chalmers, Chevrolet, Willys-Knight, Ohio electric and Maxwell. There are the following makes of trucks: Standard, Kalamazoo, Kosmath, Signal, Federal. Accessory dealers are applying for space.

—

Apperson Adds Four-Passenger Roadster

KOKOMO, IND., July 25—The Apperson Bros. Automobile Co. is placing on the market what it styles a four-passenger roadster. The driver's seat is divided from that of his companion by an aisle and directly behind there are two cornering seats with ample leg room in the aisle. The top covers all four seats but when two are not in use they are covered by the dust hood.

—

Fall Show for Denver

DENVER, COL., July 21—A two weeks' motor car and accessory show is being planned for Denver by the Automobile Trades Association of Colorado, to be held in connection with the International Soil Products Exposition Sept. 27 to Oct. 10. The exposition is expected to draw a large attendance from a wide territory, and consequently is counted upon as a substantial aid to the motor show.

The Denver dealers held a fall show last September in connection with the Denver Motor Club's two-day race meet.

—

Dallas to Have Fall Show

DALLAS, TEX., July 24—Plans are being made by Dallas Automobile Dealers' Association to have the greatest automobile exhibit at this year's Texas State Fair in October that has ever been seen in the South.

—

Hostetter Leaves Prest-O-Lite

INDIANAPOLIS, IND., July 24—Stuart S. Hostetter has resigned as head sales correspondent of the Prest-O-Lite Co. to become a member of the Hurst & Company's wholesale purchasing department. He will serve as manager of the sales and advertising department.

—

Pathfinder Prepares to Expand

INDIANAPOLIS, IND., July 27—The Pathfinder Co. has plans drawn for an addition 60 by 400 ft. to its plant to take care of the 3500 cars production for 1916.

—

New Trailer on Market

COLDWATER, MICH., July 20—A new trailer for automobiles is being manufactured by J. F. Laura, who has secured a patent for a connector used to join the trailer to the automobile. The trailer is made to carry a load of 1000 lb.

Lincoln Highway Route Changed

Washington and Baltimore To Be Included—Hercules Plant Auction Aug. 14

WASHINGTON, D. C., July 27—*Special Telegram*—Washington and Baltimore are to be on the Lincoln National highway. President Joy of the Lincoln Highway Assn., after having turned a deaf ear to appeals made more than a year ago by citizens of Washington and Baltimore, by a congressional delegation, and lastly by President Wilson to vary the course of the highway so that it might touch the national capital has notified Robert N. Harper, chairman of the committee selected last year by the District commissioners that he has found it possible to change the original plans and place both cities on the route.

Route Through Washington

Colonel Harper already has advised the commissioners of Joy's decision and the work of marking the city streets which will constitute the portion of the highway running through the district and obtaining the improvements necessary in Maryland will be taken up immediately. The highway will enter the district by way of Maryland Avenue, northeast, swing through Potomac Park past the Lincoln memorial, and then proceed westward by way of the Rockville Pike to Gettysburg.

—

Prest-O-Lite Increases Facilities for Drawn Steel Demand

INDIANAPOLIS, IND., July 21—As announced in THE AUTOMOBILE for July 22, the Prest-O-Lite Co., Inc., this city, has turned its attention to the manufacture of cold drawn steel parts and has now outfitted one of the largest plants in the country to take care of this work. At the present time the Prest-O-Lite concern has in service three 400-ton hydraulic presses, one 300-ton hydraulic press, and is at present engaged in installing what is probably the largest hydraulic press in the country, having a capacity of 800 tons. This new press is large enough to break down 60 in. in diameter steel circles ⅜ in. thick, according to officers of the Indianapolis concern. In fact, it is claimed that with this press it will be possible to draw by the cold drawing process cylinders of approximately 20 to 22 in. in diameter, 48 in. in length from ⅜ in. stock. With the present equipment cylinders 12 in. in diameter and 44 in. long from stock 0.260 in. thick are being drawn by 400-ton pressure. With the 800-ton press cylinder ends, etc., of larger diameter than 20 in. on thinner than ⅜-in. stock will be handled.

With this large capacity the ability to meet large orders on such parts as brake drums and axle housings will be readily handled on the smaller-sized hydraulic presses. On small pressed or drawn steel parts of the shallow types the Prest-O-Lite equipment includes a large series of geared presses ranging from 100 tons down to 10 tons. The equipment is such that small work can be handled practically as readily as the larger work. In fact, an order has just gone through the factory for 25,000 stampings so small that twenty-five separate pieces were required to make an ounce.

New Battery Plant

In addition to this line of work the Prest-O-Lite concern has under construction a new building 100 by 400 ft. for use as a battery factory. It is also stated by the engineers of the company that another building of this same size will probably prove necessary. The company feels that the field for drawn steel cylinders is a large one and that with the equipment and present capacity of the plant, orders of any nature may be dealt with.

—

Hercules Plant to Be Sold Aug. 14

LOUISVILLE, KY., July 23—In accordance with a judgment granted against the company at the last court term, the real estate, buildings and equipment of the defunct Hercules Motor Car Co. will be sold at auction on Aug. 14. The total amount of judgments against the company is $110,325. It is rumored that an effort is being made to interest capitalists for the purchase of the plant and continue its operation on an entirely new basis.

—

Lucas Moves to Lagrange

SOUTH BEND, IND., July 24—The Lucas Mfg. Co., manufacturer of electrical supplies and automobile accessories, which has been located in Chicago, for the last year, has decided to move the factory to Lagrange, Ind., where stock has been acquired by a number of Lagrange residents.

—

Elston Westcott Service Manager

RICHMOND, IND., July 22—C. J. Elston of Flint, Mich., has been appointed service manager of the Westcott Motor Car Co., this city. It is intended by the Westcott company to reorganize the service department completely and to thoroughly establish a policy which will follow the cars after they have left the factory. Mr. Elston was connected with the service department of the Buick Motor Co. for four years and later with the service department of the Hudson Motor Car Co.

Blue Book to Add a Volume

Will Cover Territory Below Potomac and Ohio Rivers —New Index Maps

NEW YORK CITY, July 26—The Automobile Blue Book Publishing Co., 239 West Thirty-ninth Street, this city, is going to add a new volume to its present series of Blue Books on road directions covering the territory in the Southeast below the Potomac and Ohio Rivers. Up to the present this territory has been covered partially by Vol. 3, covering New Jersey and Pennsylvania, Delaware and Maryland, and Vol. 4 covering the Middle West, but the increase in touring in the Southeast and because of greater road activity, the Dixie Highway being a typical example, a separate Blue Book will cover this territory in 1916. The Blue Book cars have already started out over the roads in this territory to get the exact road conditions and to write road guide information and will continue this work until late in the fall, thus adding route information on thousands of miles of highway in this section that have heretofore not been routed.

In this route work, the leading thoroughfares between large centers will be covered with odometer mileages, some of these being Washington to Atlanta, Jacksonville, New Orleans; Louisville and Nashville to Chattanooga, Atlanta, Florida and Gulf of Mexico; Richmond to Asheville, Chattanooga, Knoxville, Nashville, and Memphis; and New Orleans to Mobile and Jacksonville. After this secondary connecting routes will be gone over and odometer mileages written so that the tourist will be able to reach the majority of places without having to make any local inquiries. The Blue Book company is also preparing a series of general index maps, by reference to which the smallest villages in this territory can be located.

New Case Farm Tractors

RACINE, WIS., July 24—Several new types of gas power farm machinery were introduced to the public at the annual convention of branch managers and salesmen of the J. I. Case Plow Co., Racine, Wis., last week. Field demonstrations of the new Wallis Fuel Saver Tractor Cub and the J. I. Case power life engine gang plow were given on the big Case farm just outside of Racine.

—

To Build $500,000 Ford Assembling Plant in Omaha

OMAHA, NEB., July 22—A site, a block long, between Cuming and Izard and Fifteenth and Sixteenth Streets, has

been purchased in this city by the Ford Motor Co., on which will be erected a building a block long and six stories high for use as an assembling plant, general service quarters and offices.

The building will have more than 200,000 sq. ft. of floor space and will cost $250,000, and with machinery installed will represent an investment of $500,000. The ground, on which the building will be erected, was bought last Saturday, the price, about $105,000, being paid by Manager Charles Gould of the Ford company, Fred C. Shields, realty broker, and ex-Lieutenant Governor McGilton, attorney for the Ford company, to the various owners.

Three hundred men will be employed in the salesrooms, service station and assembling plant at the outset, after next April, when the building is expected to be finished. The Ford Motor Co. minimum wage of $5 per day will be applicable to all.

—

Continental Adds to Muskegon Plant

DETROIT, MICH., July 24—The Continental Motor Mfg. Co., this city, is making extensive additions to its Muskegon, Mich., plant, which is devoted almost exclusively to the production of four-cylinder motors. Two reinforced concrete buildings, four stories in height will be constructed, one being 54 by 150 ft. and the other 70 by 330. Production of four-cylinder motors will be increased from 4000 to 6000 per month.

—

Studebaker Not to Move Plant

SOUTH BEND, IND., July 24—President Erskine of the Studebaker Corp. denied the report from New York concerning the probable extension of the home plant in South Bend by the purchase of $800,000 worth of property here. "We have more room than we need here. We will positively not move the Detroit force here, and I cannot account for a rumor concerning the purchase of land," said Mr. Erskine.

—

Miller Rubber to Build $50,000 Addition

AKRON, O., July 23—The Miller Tire & Rubber Co. will build a $50,000 addition. It will be six stories and 109 by 154. Another smaller building, one story and basement, 57 by 40, is also to be a part of the extension. The company has made extensions during the year which, with the proposed building, will bring its building expenditures close to $200,000.

—

Haynes Not to Move

KOKOMO, IND., July 27—General Manager Sieberling of the Haynes Automobile Co. emphatically denies the rumor that his company will move to Lackawanna, N. Y. Rumors to this effect were circulated around Buffalo some weeks ago but are entirely false.

32,000 Cars in Oklahoma

—

New Law Works Out Well—$40,000 Fees Collected—Oklahoma City Statistics

OKLAHOMA CITY, OKLA., July 23—Oklahoma's new law has been in effect since July 1, and during the first three weeks of the month, the State highway department has collected nearly $40,000 from automobile owners for licenses for their cars.

State Highway Commissioner A. N. Leecraft estimates there are 32,000 automobiles in the State.

Under the new law car owners must pay the State a license tax for their car, based upon the horsepower. For every horsepower the owner must pay 50 cents. This tax is in lieu of all other taxes, and is in great favor with automobile owners who compare the new tax with the tax under the old law. Ninety per cent of the money collected goes to the county from which it was originally collected and 25 per cent of the 90 per cent goes to the city where the car owner resides.

There are now 1900 automobiles in Oklahoma City worth approximately $700,000. The horses number 1343 and are valued at $66,350. The mules number seventy-five with a value of $4,435. The total number of horses and mules is 1418 and the value of both but $70,785. These figures were obtained from County Assessor J. S. Morrow.

The motor car has not made rapid gain in the county outside the city. The automobiles in the county, exclusive of Oklahoma City, number less than 100. The bad roads are largely responsible for this condition. Yet the total value of horses in the county, including Oklahoma City, is less than the value of the motors.

There are 9600 horses in the entire county worth $553,092 as compared to $717,915, the value of all the automobiles in the county.

On the basis of 75,000 population an average of one person in 39 owns an automobile in Oklahoma City.

—

To Build Hearses and Ambulances

GRAND RAPIDS, MICH., July 24—The Michigan Hearse & Motor Co. has been organized to succeed the Michigan Hearse & Carriage Co., which has been in business during the last twelve years. As the name indicates the new concern has done away with carriages and horses and will now build motor-driven hearses. These will be made at its own plant, as well as ambulances. The old plant of Walter Poor and Harry Yeider, on Wealthy Street, has been secured, and there, temporarily, the chassis will be built. They will have a wheelbase of 148 in. and carry a six-cylinder motor. The capital stock of the company is $150,000 of which $25,000 is preferred. A two-story plant, 45 by 125 ft. is to be erected at Cottage and Grove Streets and Union Avenue.

—

Republic Truck to Add Again

ALMA, MICH., July 24—Although the Republic Motor Truck Co. made additions to its plant several months ago, the growing business has again made it necessary to further increase its size. At the present time two one-story buildings are being constructed. One is to be 30 by 450 ft. and will be used as a storeroom. The other, 50 by 100 ft., is to be the body shop. The total floor capacity of these buildings will be 18,500 sq. ft. Further extensions are contemplated which will add 20,000 more sq. ft.

—

Select Ford Nashville Site

NASHVILLE, TENN., July 24—For the purpose of selecting a site for the new assembling plant of the Ford Motor Car Works of Detroit, to be established in Nashville, M. N. A. Hawkins, an official of the company, was in Nashville Monday. Mr. Hawkins inspected some half dozen prospective sites for the new plant, which is to have a capacity for 15,000 cars annually, and which will give employment to about 700 men.

—

Lawrence Wants Austin Plant

LAWRENCE, MASS., July 24—The Industrial Committee of the Lawrence, Mass., Chamber of Commerce, having succeeded in getting the Lenox Motor Car Company to move to that city is now after other motor concerns, and an offer has been made to the Austin Automobile Co., Grand Rapids, Mich., to move East.

—

Nicholson Regal Asst. Sales Manager

DETROIT, MICH., July 26—E. W. Nicholson has been appointed assistant sales manager of the Regal Motor Car Co. During the last two years Mr. Nicholson had charge of Chalmers district sales work.

—

Buller Joins Apperson

KOKOMO, IND., July 22—H. L. Buller is now connected with Apperson Bros. Automobile Co. in charge of advertising.

—

$15,000 Fire in Fisk Plant

SPRINGFIELD, MASS., July 23—Fifteen thousand dollars worth of building materials and four freight cars were destroyed by fire and a gasoline explosion in the yard of the Fisk Rubber Co., Chicopee Falls, late last week.

Jitneys Win in Indiana

P. S. C. Refuses Trolley Co. Petition That Commission Take Control and Regulate

INDIANAPOLIS, IND., July 24—The public service commission to-day entered an order dismissing the petition of the Terre Haute, Indianapolis and Eastern Traction Co., which sought to bring all jitney buses in the State under the control of the commission and subject to regulation by the commission.

At the hearing attorneys for the traction companies argued that the jitneys were common carriers and public utilities within the meaning of the utility law, and ought, therefore, to be regulated.

The commission's order was brief. It simply set out that the body had no jurisdiction and therefore dismissed the case. While the original petition related only to Terre Haute, the hearing on the proposal to place all jitneys under the regulation of the commission brought in the entire question of jitney competition with electric roads throughout Indiana. The commission was in session practically all day and prominent public utility magnates from all over the State attended the hearing.

—

Kansas City Jitneys Raise and Lower Fares

KANSAS CITY, MO., July 24—The jitney bus died, was born again, died again and was born once more all in the course of two days here last week. The Green Bus Line, outfitted with fifteen of the Studebaker medium-priced buses, went out of the hands of the company that has been operating them, through foreclosure. The Studebaker Corp. sold the buses on what its manager here described as a "shoe-string capitalization." The promoter of the company had no money to begin with and the Studebaker company sold the buses largely with a view to encouraging the industry. But the officials of the company lacked the business instinct and the payments fell behind. When the fifteen green buses went out of business, the White Star Line, a co-operative company, immediately announced that it would charge 10 cents and that action was followed by the other buses and dozens of the smaller touring cars. They were stampeded by the fate that had overtaken the green bus line. However, the competition of the small jitneys that had not changed from 5 cents and the fact that the women preferred the street cars at 5 cents, brought a change the day following and the buses and the smaller jitneys that had changed their price all went back to 5-cent fares. The days the buses were charging 10 cents found them filled only in the rush hours, when the men were going to and from work.

There are practically as many buses and small jitney cars on the streets as there were earlier in the season. The Studebaker company is reselling its cars that were taken out of service as rapidly as possible.

—

Erdman-Guider Co. to Make Bodies

DETROIT, MICH., July 26—The Erdman-Guider Co. has been organized to make special automobile bodies and do a general automobile trimming, repairing and painting business. The concern has leased the old Herreshoff Motor Car Co. plant 2290 Woodward Avenue. Those interested in the new concern are A. R. Guider, president and business manager, who during the past 10 years was manager of the R. Herschel Mfg. Co., Saginaw, Mich.; Charles Erdman, vice-president who was vice-president and assistant general manager of Seivers & Erdman; H. L. Morrison, secretary-treasurer, who was connected with the accounting department of the Riverside Storage Co.

—

Weatherproof Body Co. Organized

DETROIT, MICH., July 26—The Detroit Weatherproof Body Co. has been organized and incorporated, its capital stock being $10,000. The officers of the new concern are C. Haines Wilson, president and treasurer; Lawrence Moore, vice-president and general manager; George D. Wilson, secretary. Temporarily the headquarters of the company will be at 500 Clay Avenue. The new concern will make limousine tops, commercial car bodies and will also market a special Ford body.

—

Smith a Regal Sales Manager

DETROIT, MICH., July 27—H. H. Smith, formerly sales manager of the Diehl Mfg. Co., Elizabeth, N. J., and recently with the Triumph Electric Co., Cincinnati, O., has become district sales manager for the Regal Motor Car Co. with headquarters in San Francisco, Cal.

—

Denby Truck Reduces Prices

DETROIT, MICH., July 23—The Denby Motor Truck Co. has reduced prices from $115 to $215 on its three models of trucks. The trucks themselves have not been altered.

The 1-ton or model B is now listed at $1,475, $125 less than formerly; model D, 1½-ton, lists at $1,685 or $215 less than heretofore, and the 2-ton model E at $1,985, which is a cut of $115 from the former price.

These lower-price Denby trucks have the same constructional features a equipment as before the new prices we into effect; in fact, there are no chang of any kind excepting the price.

—

A. S. Bowser Goes to Albany

SOUTH BEND, IND., July 24—A. Bowser, formerly secretary of the S. Bowser Co., Fort Wayne, Ind., has be transferred to the position of assist general manager of the Albany, N. office. President Bowser said no p manent secretary will be appointed the home office for the present and transfer of the president's son to Eastern office is not the first of a change in Bowser officialdom.

—

Bourquin Leaves Paige-Detroit

DETROIT, MICH., July 27—Jas. Bourquin, general manager of the P Detroit Motor Car Co., has resigned. was formerly with the production partment of the Chalmers Motor C

—

Hood Detroiter Sales Manager

DETROIT, MICH., July 26—Walla Hood, who was sales manager o former Briggs-Detroiter Co. has appointed to a similar position i new Detroiter Motor Car Co. Mr. previous to his connection with Briggs-Detroiter Co. was sales ma of the Standard Motor Truck Co Everitt Motor Car Co. and als Chalmers Motor Co.

—

Pierce-Arrow Agency Officials M

BOSTON, MASS., July 24—The o of the leading Pierce-Arrow a east of the Mississippi held a tw meeting at Boston, Mass., this w W. Maguire, the Boston agent, the part of host. They discussed matters of interest to the busine between times played golf and There were present Col. Charle ton of Buffalo; R. D. Gerton and Cady of New York; Charles Han Cincinnati; D. E. Odell of Minn Grant Waldraf, St. Paul; C. ford and E. H. Stoddard of Spr Mass.; H. Paulman of Chicago; Ellis of Newark, N. J.; Herman Pittsburgh; Samuel Berdeaon Louis; J. B. Westefeld, New Conn.; W. J. Foss and W. R. F Philadelphia; E. C. Bull, W. and R. Patten of Buffalo.

—

Post Stearns New York Sales

NEW YORK CITY, July 25—T Stearns Co. of New York has F. W. Post, Jr., sales manage secretary Thomas R. Jacobs, he out the duties previously perf William Arthur Lesser, who in an automobile accident last n

Orr Plant at Yazoo City—The Orr Modern Motor Co., recently organized, will construct a plant at Yazoo City, Miss., for the manufacture of automobiles.

Auto Crank Shaft to Add—The Auto Crank Shaft Co., Piquette Avenue, Detroit, Mich., has awarded the contract for the construction of a one-story brick addition to its factory.

Toledo-Ford Tire Addition—Plans are being made for the construction of a new addition to the Toledo-Ford Tire Co.'s factory on Western Avenue, Findlay, Ohio. It will be 50 by 130 ft. and four or more stories high.

Wilson Foundry to Double Plant—The Wilson Foundry & Machine Co., Pontiac, Mich., expects to double its plant within the next few months. For this purpose about 10 acres of land have been purchased recently. The present force of 600 will be doubled, it is said.

Saxon Ships 11,000 Cars—During the first six months of 1915 the Saxon Motor Co., Detroit, Mich., has shipped about 11,000 Saxon fours and sixes. Production is being increased gradually and it is expected by officials of the company that the output for the remainder of this year will be at least equal to that of the first half.

To Enlarge Building—The Gas Power Engineering Co., operating a large garage and machine shop at North Avenue and Second Street, Milwaukee, is about to increase its capacity by the construction of a complete third story. The original building consisted of one story, and a year and a half ago a second story was added. The building is 60 by 150 ft.

Des Moines Co. to Build—The Clemens Auto Co., Des Moines, Iowa, has bought an eighth of a block on Eleventh and Mulberry Streets at a cost of $40,000 and will build a four-story, fireproof brick building thereon to cost $40,000. It will house the business of the company after Jan. 1, 1916. The company handles the Overland car for the Des Moines territory.

To Make Piston Rings—The Continental Piston Ring Co., Memphis, Tenn., has been incorporated with a paid in capital of $100,000. It will manufacture piston rings for locomotives, engines, automobiles and pumps of various kinds. The officers are B. H. Mason, president; W. P. McCadden, vice-president; R. E. Brown, secretary and treasurer, and C. R. Bryant, chief engineer.

Bulford to Enlarge Plant—The Bulford Truck Co. has decided to erect a large addition to its factory in Fremont. H. G. Bulford, the president, who leaves this week for England, announces that the company will turn out a large number of motor ambulances for Red Cross service in Belgium and France. As soon as the addition is completed, a large increase in the working force will be made.

Victor Tire to Build Again—The Victor Rubber Co., Springfield, Ohio, will erect another building, to be two stories, 30 by 108 ft. It will be erected on the ground between the two wings of the main factory building. The addition will be much like the one which was completed a few weeks ago. A mileage capacity test is now being made of the new pneumatic tire made by this concern. An automobile has been equipped with a set of these tires and will be run 300 miles a day while they last.

American Brass Adds—The American Brass Co., Kenosha, Wis., has just completed a large brass foundry addition in record time. Just thirty days after the contract for the erection of the shop was signed by the American Bridge Co. the building was turned over to the owners for installation of equipment. The shop is of steel and sheet iron, 330 ft. long, 60 ft. wide and 27 ft. high. The extraordinary demand for brass goods, particularly from the automobile trade, made the erection of the addition imperative.

Wisconsin Breaking Records—The Wisconsin Motor Mfg. Co., Milwaukee, is working the longest hours and the largest force of workmen in its history, due to the extraordinary demand for motors from car and truck manufacturers. The company some time ago reached the highest production it has ever known, but this was insufficient to meet specifications and schedules have been extended to the full limit of the plant's capacity. It is likely that additions will be made during the winter months in anticipation of a continuance of the demand for 1916.

Kansas City Ford Expands—The Ford Motor Co. is preparing to make an addition to its plant in Kansas City, Mo., to cost about $175,000. The addition will be two buildings, one 54 by 75 ft., the other 120 by 400 ft., both three stories, of reinforced concrete and tile roof. The work will be completed by Dec. 31.

March 4-11	Boston, Mass., Truck Show, Mechanics Bldg.

The Week in the Industry

Rogers Forms New Co.—Mason T. Rogers, up to the present time manager of the Buffalo, N. Y., branch of the Packard Motor Car Co., has resigned to enter business for himself. He has formed a firm styled M. T. Rogers & Co. and has associated with him C. W. Burton, formerly of the Daniel Green Felt Shoe Co., L. E. Moore, formerly connected with the Packard Philadelphia branch, and E. C. Fish, recently connected with the Buffalo Hudson company. The new company will gradually absorb the business of the Universal Equipment Co., supply dealer.

Jones Represents Midgley—Temple Jones, who has been connected with the Tire Sales Company, 204 St. Paul Street, Baltimore, Md., representatives of the Midgley and Republic tires, has become the direct representative of the Midgley company.

Dealer

Opens New Salesrooms—The Collins-Clem Auto Co., agent for the Studebaker in San Antonio, has opened new salesrooms and service station at the corner of Navarro and Crockett Streets.

Fanning to Handle Apperson—Frank Fanning, local distributor of the Marmon in Philadelphia, Pa., and W. T. Taylor, wholesale representative of the Apperson, have entered into an agreement whereby the Philadelphia Apperson retail trade will be handled by the Fanning company.

Maxwell Dealers Gather—Ralph Coburn, Eastern district supervisor of the Maxwell Motor Car Company, had the New England dealers as his guests at a meeting in Boston last Wednesday and Thursday, when he showed them the new 1916 Maxwell car. There were more than fifty present.

Overland Dealers Meet—The seventy-five Overland dealers in Eastern New England met at the Hotel Lenox last Friday night at a dinner as guests of the Connell & McKone Co., Greater Boston distributors of the Overland products. Joseph McDuffie, assistant sales-manager of the Willys-Knight, was guest of honor.

Used Car Week—The Rooke-Osmond Motor Co., Milwaukee, Wis., State distributor of the Jeffery, repeated its Used Car Week selling campaign last week and disposed of practically its entire stock of used cars, many for jitney purposes.

Motor Men in New Roles

Talbot Pathfinder Mgr.—W. E. Talbot, 408 Sumpter Bldg., Dallas, Tex., has been appointed Southern district sales manager for the Pathfinder Motor Car Co. of Indianapolis.

Austin Metz Sales Mgr.—Harry D. Austin has been made sales manager for the Seattle Metz factory branch, after a year's absence with the Metz company in California.

Fick Monarch Purchasing Agent—F. B. Fick, formerly with the Abbott Motor Car Co., has been appointed purchasing agent of the Monarch Motor Car Co. Detroit, Mich.

Knaus Makes Change—A. H. Knaus, formerly district manager for the Chalmers in southern California, has been made sales manager of the Braley Auto Co., Franklin distributors in Portland, Ore.

Abel Houk Agent—George I. Abel, western agent for the Houk Mfg. Co., has opened a branch in San Francisco to handle the Houk wire wheel. Abel is the representative for seven western States.

Kidd Paige District Mgr.—S. W. Kidd has been appointed district sales manager by the Paige Motor Car Co. with headquarters in St. Louis. He was formerly connected with the Detroiter Kansas City Co.

Chandler Noxall Distributor—W. R. Chandler, president of the Spar-East Co., eastern distributor of Sparton horns and other Sparton products, has become the eastern distributor for the Noxall Shock Absorber made by the Baker-Duffy Co., Chicago.

Donovan in Business—Frank B. Donovan, long associated with the Donovan Motor Car Co., Boston, has entered the trade in Baltimore, Md., as Studebaker distributor under the style Frank B. Donovan, Inc. Frank Carthew is president of the concern, and Donovan is treasurer and general manager. An office, salesroom and service station will be opened at 10-20 East North Avenue.

Ridenor with Madison—K. A. Ridenor, for several years in charge of the Louisville office of the Waverley Electric Co., has resigned to become assistant to Roy Potts, vice-president of the Madison Motor Co., Anderson, Ind. Mr. Potts formerly was sales manager of the Waverley Co. at Indianapolis. George Cheschire, southern representative of the Waverley Co., is temporarily in charge of the Louisville office of the Indianapolis concern.

Balough's Headquarters in Springfield—Charles Balough, who has been identified for the last five years with The Kelly-Springfield Motor Truck Co., Springfield, Ohio, as chief engineer and works manager, resigned from that company last June to take up the development of a new proposition in the commercial car field. Mr. Balough announces his headquarters as Columbia Street and Dakota Avenue, Springfield, Ohio, where he is conducting the development work of his new connections.

Kenny Returns to St. Louis—F. C. Kenny, who for four months was manager of the Studebaker branch at Memphis, Tenn., has returned to St. Louis and resumed the duties of assistant manager of the St. Louis Studebaker branch, which position he held before going to Memphis.

Garage

Garage and Repair Shop—John Gumb is erecting a $12,000 garage and repair shop building at Teutonia Avenue and Alten Street, Milwaukee, Wis. It will be 30 by 125 ft.

New Baltimore Garage—The Central Automobile Co. has opened a large garage in Baltimore, Md., in a place which was constructed by the city as a market house. The company can care for seventy-five cars. Twenty-four-hour service and accessory service is maintained.

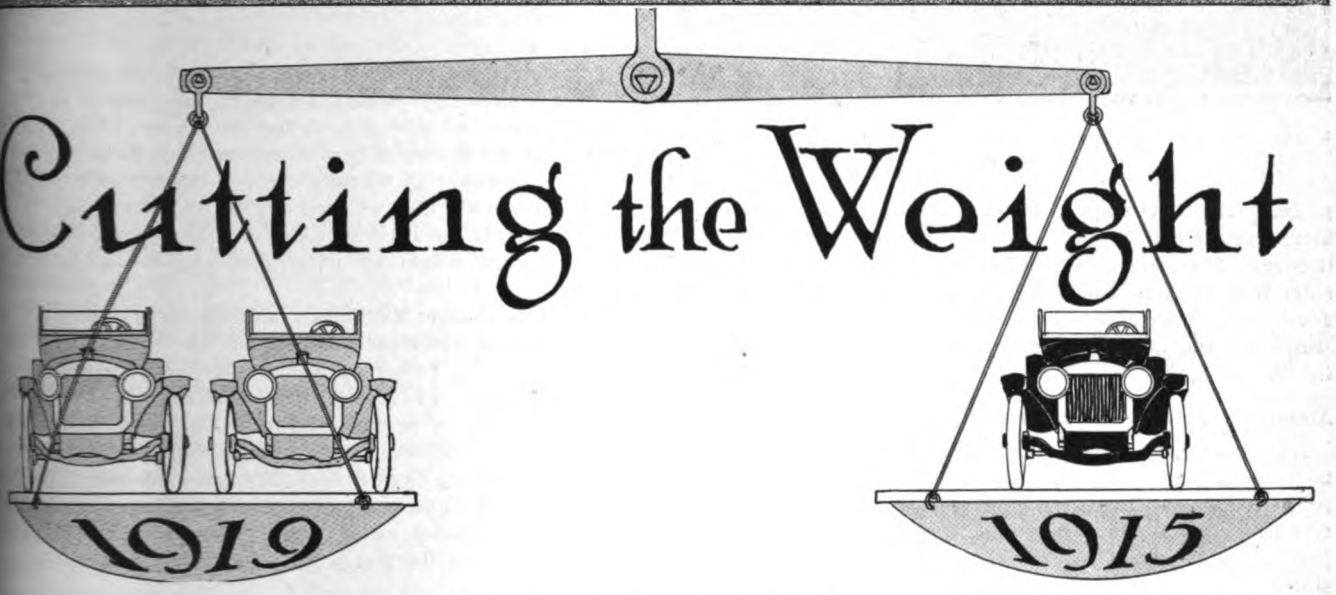
Build New Garage—Dvorak & Gaynor, Kewaunee, Wis., have broken ground for a new garage 40 by 120 ft. The business was established by the late John Gaynor in the spring of 1912 and is being continued by his son and J. F. Dvorak. The concern represents the Chalmers and Dodge.

Recent Texas Garage Happenings—The Lone Star Motor Co., El Paso, Tex., has moved into its new building, at Chihuahua and Overland Streets. It now has 24,000 sq. ft. of floor space at its disposal. The company has secured the Southwestern distributing agency for the Chalmers and handles Dodge, Hupmobile and Chandler. The Federal Tire Co. has opened an agency at El Paso, in the Overland Building, with F. M. Bannell in charge. The Federal Motor Truck Co. has placed the distributing agency for its products in Houston with the Houston Motor Truck Co.

Vol. XXXIII NEW YORK—THURSDAY, AUGUST 5, 1915—CHICAGO No. 6

The AUTOMOBILE

Cutting the Weight



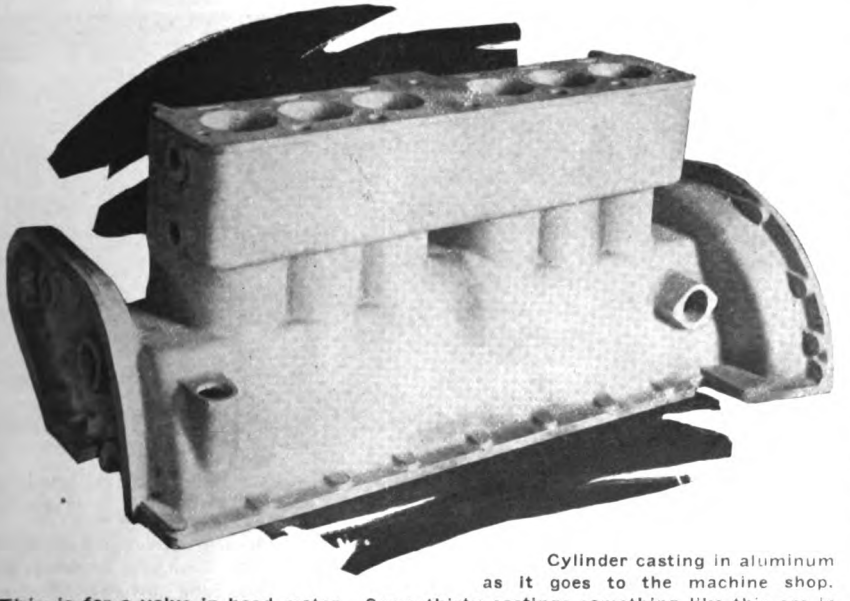
How Scientific Design and Use of Aluminum Alloys Will Cheapen Motoring

By A. Ludlow Clayden

THE automobile of 1918 ought to be 30 per cent lighter than the automobile of 1916.

Correspondingly it ought to be anything from 20 to 40 per cent cheaper to run, but it may cost a little more to buy. Surely, however, a matter of a few hundred dollars ought not to be considered if they are to be saved over and over again in the first year's use of the car.

Weight which is not doing work is dead weight and there is no place for anything but live parts in an automobile. Dead weight cannot ever be cut out entirely, but in most cars there is a great mass of needless metal of which the only effect is to eat up tires and gasoline. We know now the sort of road performance expected of the modern automobile and we cannot look for anything greater in the way of ability than is given by a good six, eight or twelve, but we could get the same ability with much less weight and so be able to utilize it for much less money. Engineers have worked for twelve years upon little else besides the motor so would it not be reasonable to turn to a new problem for a while and apply the same brain effort to improving the whole of the chassis?

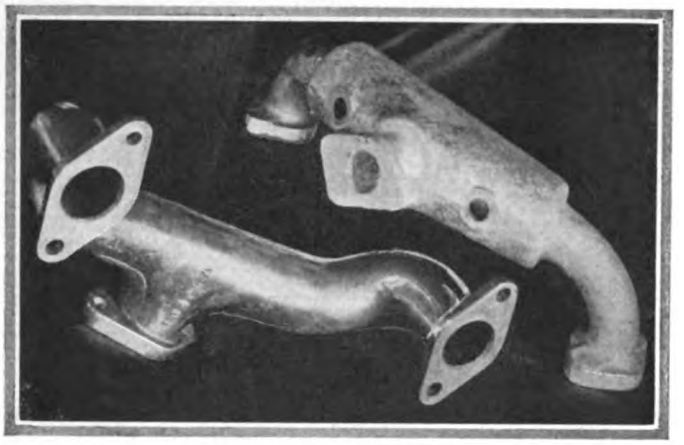


Cylinder casting in aluminum as it goes to the machine shop. This is for a valve in head motor. Some thirty castings something like this are in service in the hands of private owners throughout the country

How to Reduce Weight

There are two ways of reducing the weight of a car. One is to dispose the material more scientifically. The other is to use much more aluminum alloy of one sort or another.

In the following it is purposed to give attention principally to the latter possibility, using more aluminum and to show how much more extensively aluminum could be used with



Everyday aluminum pieces. A plain and a water-jacketed intake manifold

nothing but advantage. To cut the weight by using light metal means thinking of ounces here and odd pounds there, it means that with every detail of a chassis we must consider how light it can be made, taking nothing for granted from past experience. But before going into detail a few words on the history of aluminum in the automobile may be said.

Aluminum Returns from Obscurity

Aluminum was such a weak metal when automobile engineers first began to use it that it had to be extremely massive in order to obtain the necessary strength. Thus we found frequent claims that a crankcase, for example, could be made just as light of cast iron; with the gearbox it was not possible to house bearings directly in the aluminum, because the soft metal would gradually sink away and leave the ball race loose and rattling, and it was not safe to use aluminum for the middle part of a rear axle, as it was liable to bend out of shape and then crack. Also aluminum cost a good deal of money so altogether it was not a very encouraging material ten years ago.

Then came a slow change as founders discovered how to alloy the light metal with copper, zinc and other substances, but the engineers who had turned to the use of iron and steel for parts once made of aluminum were satisfied with what they had done and did not feel inclined to give aluminum another chance.

This brought us to the stage where the unit power plant appeared and this weighed altogether too much if the base was anything except aluminum, so engineers then discovered what a vastly different sort of metal aluminum had become. To-day it is almost as strong as cast iron and can be stronger. It has a high power of resistance to shock, can be cast very accurately, machines more easily than any other metal and its quality is regular while its quantity is infinite.

There is practically no *cast* portion of an automobile which cannot be made of aluminum with utterly satisfactory results both in the shops and on the road, and we may soon see some forged parts replaced by the lighter metal.

Aluminum Cylinders to Be Used

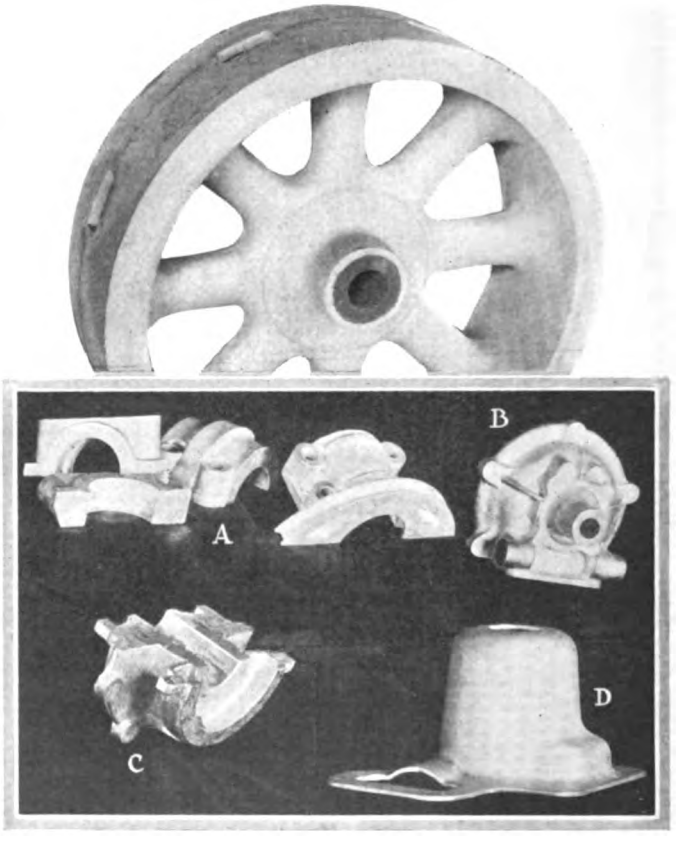
Having said that there is no casting in an automobile chassis that cannot be made of aluminum let us begin with the cylinders, the largest cast part and the one which seems the least susceptible of aluminumizing. Next year there will be several cars in regular use with cylinders of aluminum and one of the biggest motor builders actually sent out a dozen or more motors this spring with cylinders of this metal, painting them so that the fact was hidden to the buyer. The results have been so satisfactory that more than one prominent engineer is preparing to start in with aluminum cylinders as standard.

Here let it be explained that there are two parts of the cylinder which cannot be aluminum, the valve seats and the wall against which the piston works. In the motors already made up a very thin iron liner has been used to make the piston working surface, and a little iron plate is cast in to form the valve seatings. The cylinder liner is as thin as the machine shop can make it, as thin or thinner than a sleeve of a Knight motor, and there is even a possibility that it *may* be found possible to run the piston in a cylinder of unlined aluminum. This is a matter of experiment, calling for investigation with different alloys, but even with the compound construction the weight of the iron is very little indeed.

The aluminum cylinder block can be cast with walls of exactly the same thickness as would be used for cast iron, because an iron cylinder's dimensions are determined by the limit of thinness to which a foundry can work and not by considerations of strength, so the weight saved is directly in proportion as the weights of aluminum and cast iron.

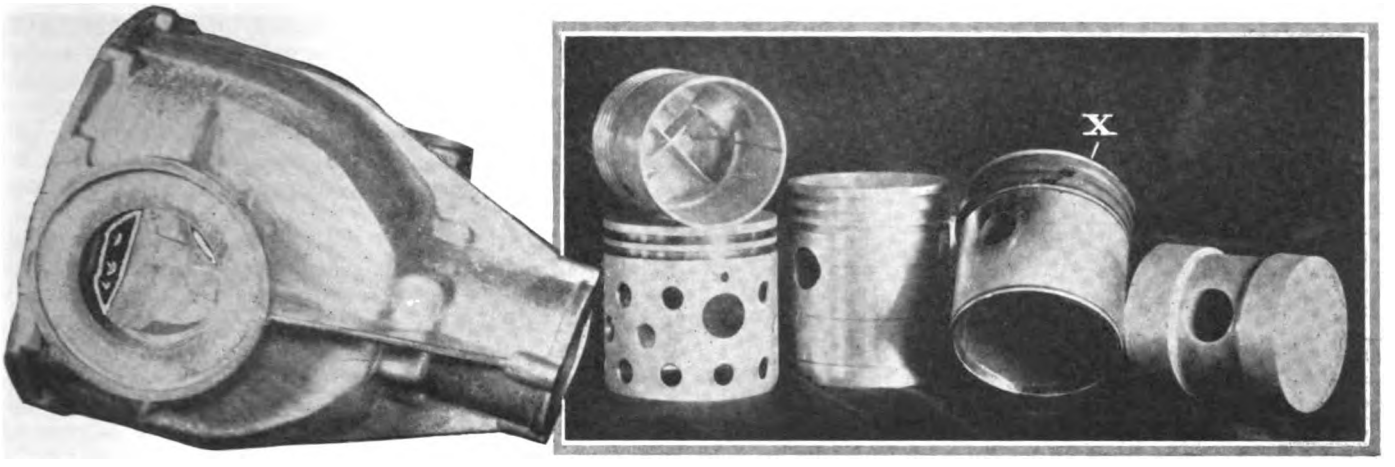
As an example let us take a six-cylinder block casting for a 3 by 5 motor. One of good design by actual test, weighed 119 lb. and as the ratio of weights is between 2.5 and 3 to 1 the saving in weight by using aluminum would be 72 lb. at least.

There is another advantage too, which is often forgotten in thinking of aluminum pistons, and this is the much better heat conducting power of aluminum. Heat conductivity is often measured by taking that of silver as 100. On this basis iron has a conductivity of 11.6 and aluminum 31.3 which means that heat flows through aluminum nearly three times more easily than it does through cast iron. The effect of this is that aluminum pistons and cylinders part with their heat to the cooling water much more quickly. In a motor that is running, the piston and the inside cylinder wall are



Above—A sand cast aluminum truck wheel. Many of these are in use and are said to save as much as 1000 lbs. on the whole weight of the vehicle

Below—A—Permanent mold bearing caps. B—Permanent mold pump casing. C—Sand cast cover showing how thin sand casting can be done. D—Sand cast bearing cap which compared with those from the molds shows the machining saved by the latter process



Left—An elaborate permanent mold job. A differential casing which needs hardly any machining. Right—Pistons cast by the permanent mold process. That marked X ran for 490 consecutive hours at 1300 r.p.m., equivalent to 17,000 miles on the road at 35 m.p.h.

a good deal hotter than the water in the jackets and with aluminum cylinders there is still a temperature difference, but it is not so great. Now, as it is the temperature of the piston and cylinders which controls that of the valves, and also influences the efficiency of the lubrication, it follows that the aluminum motor will run cooler at high speed than the iron engine. This is what might be called an accidental advantage, for the weight saving is the really important thing, but it is an added reason for using the better material.

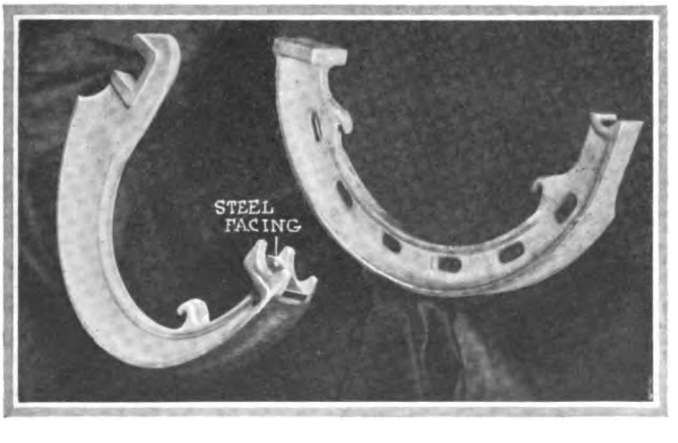
200 Pounds Saved

Several good engineers have been drawn to the extended use of cast iron, because a cylinder block which has the top part of the crankcase integral with it gives a very rigid support to the crankshaft. Now, just the same rigidity can be had with aluminum cylinders and crankcase in one integral piece and the weight saved, as compared with integral cast iron would be probably 200 lb. or more on a 3 by 5 six-cylinder motor. On an eight it would be almost as great proportionally and similarly on a twelve.

The little Sterling motor, illustrated by a sectional drawing, is said to weigh nearly 100 lb. less than the standard model. Not only is this immense saving an advantage when the car is completed and tire wear or gasoline consumption come to be considered, but it makes a perceptible difference in the cost of freight on the rough castings, and still more in the machine shops. A six-cylinder block which can only be handled with great difficulty by three men becomes light enough for two to play with or for one to carry a short distance, and in a big production shop this would cut the labor cost by an appreciable amount as well as speed up the handling. Also, apart from handling, the machining of the aluminum is a vastly quicker job than with cast iron.

So there is plenty to be said in favor of aluminum on the cost side, which goes to offset the slightly greater expense of the casting in the first instance. No doubt aluminum cylinders would cost more than iron at the present time, but there is no reason why they could not become as cheap if a large plant was organized on an aluminum basis.

With connecting rods the experimental stage has not yet been advanced very far. Two kinds are possible, those made up from pressings of sheet metal welded together, and those cast or die-cast. The former have been tried out in one or two aeroplane motors with success and the latter have been tried in some small cycle motors, also with encouraging results. It remains for the future to show whether the metal is easily applicable to ordinary automobile work but there seems no fundamental reason against its ultimate success.



Two aluminum brake shoes. The part indicated on the left one is a bit of steel cast in to take the cam wear

Untried Possibilities Numerous

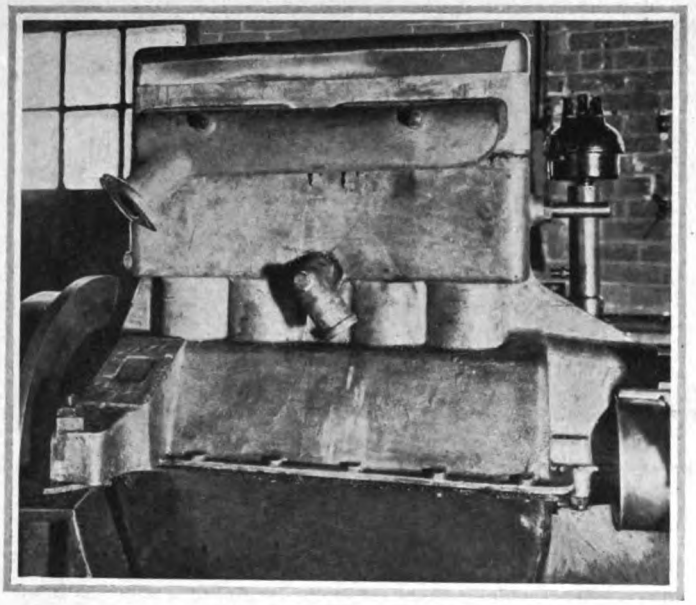
In a motor the crankshaft, camshaft, tappets, valve seats, cylinder liners and distribution gears must be iron or steel.

Crankcase, cylinder block, pistons, connecting rods, pumps water header and carbureter, intake manifold, piping and the metal parts of ignition apparatus can be aluminum.

This is speaking broadly, for aluminum could easily be compounded with the steel parts in several instances. Take the timing gears for example, or the sprockets, if chain distribution is employed. There is no reason why these should not consist of aluminum centers having a steel rim on which the teeth are cut. Compound casting could produce such a wheel, and it would not be difficult to devise a method of attaching a steel ring to an aluminum blank by other means. It may even be possible before long to make a die casting wherein a *finished* ring gear of steel is filled with a ribbed aluminum center and turned out of the mold ready to go on the shaft. Of course, it sounds as though going to an extreme of this sort would be absurd, but the saving in weight might easily be 5 or 6 lb. or even more and it is by detail cuts of this sort that the total chassis weight must be reduced in the future.

As another instance take the steel parts of a leather ring or other form of coupling used to drive a generator or a magneto, for these are designed for convenience and not for strength and might just as well be aluminum. Probably, allowing for the saving in machining cost, they would come out actually cheaper.

Other parts which might advantageously be of aluminum are such things as starter brackets, the small levers used in the control mechanism, fan, fan bracket and fan driving pulley, all cover plates, breather or oil filler caps. Other details will suggest themselves as soon as this line of thought is followed and it is a conservative estimate that a motor with aluminum used to



An aluminum Sterling motor which has been running for weeks on the block in the manufacturer's plant. This motor is 100 lb. lighter than the cast iron equivalent and keeps much cooler. It is expected that a large number of aluminum Sterling engines will be used next year

the practical limit would weigh little more than 50 per cent as much as a similar motor with much cast iron in its make up.

Attention may be drawn to the undoubted fact that the die cast, or permanent mold, aluminum piston is far past the experimental stage and it is within measurable distance of being as cheap as cast iron, while being much cheaper than steel. Its lesser weight reduces the total weight of the motor, the vibration stresses and the wear on bearings, while its better conductivity causes it to keep cooler and so allows a higher piston speed without ill effects. In a year from now or even less, it will be possible to say the same of aluminum cylinders, save that their use does not affect vibration or bearing stresses.

With the small, and less important parts, the designer who is seeking to save weight should consider each piece to make up his mind whether it would be strong enough in aluminum. On most good motors there are many pounds of steel and brass parts which would do their work just as well whatever they were made of, and when we get a piece like this it ought to be aluminum.

Let it not be forgotten either, that aluminum exists in sheet as well as in ingots and that its great ductility enables it to be pressed or spun into elaborate shapes. For strength it can be corrugated or ribbed and the necessary dies for making parts of simple contour can be prepared from cheap castings.

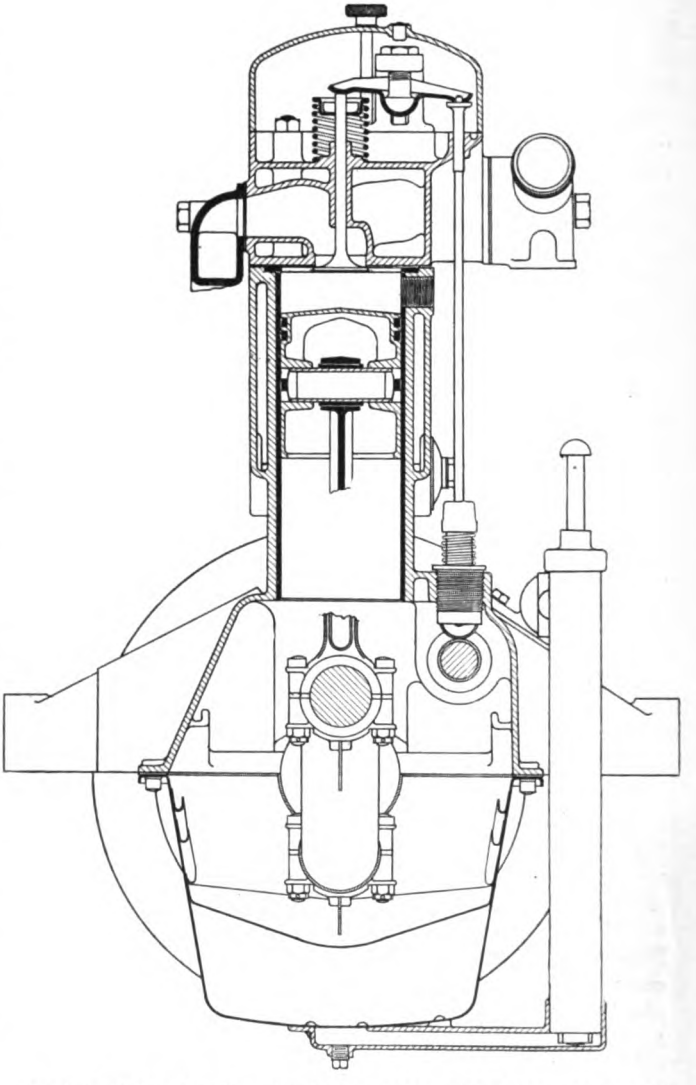
No mention has been made of the exhaust manifold but this is a part which must be of some material capable of withstanding high temperature long continued. Aluminum deteriorates slowly if used for the exhaust branch, unless it is water cooled, and if it is jacketed the extra weight of the larger amount of water necessary in the system would more than counterbalance the saving on the part itself.

Small Parts in Transmission

Now coming to the clutch if it is a cone type we can obtain the lightest center by using aluminum, and if it is a plate pattern with fabric facing there is a possibility of using aluminum to carry the fabric. Probably the clutch is one of the parts least susceptible to the introduction of light metal, and it is certainly the part where weight matters least, as it all goes to make up flywheel mass which is controlled by the needs of the motor. We must have enough weight here in any case and cannot cut it out. Almost the only opportunity for introducing aluminum in the clutch operating gear appears to be the foot plate of the pedal. Pedals in which the foot plate is a separate part adjustable to suit drivers of different stature are becoming increasingly popular, and there is no possible objection to the use of a light alloy for the actual pedal, though it could not be employed for lever parts.

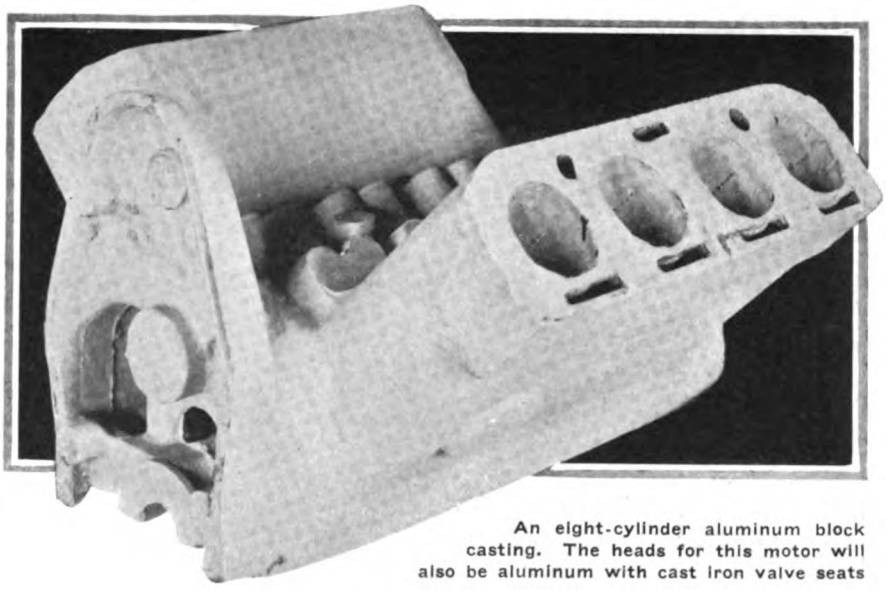
Transmission, in so far as the gearbox is concerned, can have an aluminum case for practically the same cost as cast iron, and, of course, it usually does so. Neither shafts nor gears could be anything but steel, and the shifting mechanism must be steel also. There should be no need for brass parts. Aluminum can be employed for the quadrant, if such is used, or for the spherical housing for the foot of the gear shift lever. The levers themselves for gears or emergency brake can be lightest if of steel, but they are almost always needlessly heavy. Some most excellent and very light levers have been made from drawn steel tube with aluminum handles and drop forged lower end brazed in. No doubt they cost more than the plain type, but there is a chance of dispensing with several pounds on these two levers.

Where pressed parts are used, such as cover plates, protecting shields for the quadrant and so on, they are better of sheet metal than castings as a rule, but they might be



Section of the Sterling aluminum motor. The black parts show the iron which remains. The liner is pressed in and is previously turned up, the bore being ground after assembling in the aluminum. To make the valve seats a thin steel plate is used, also shown in black section. The connecting-rod has been cut and the upper half turned round to show the section of the Lynite piston

pressed aluminum just as easily as pressed steel and with very little extra cost. Another use for sheet aluminum where it effects a great saving is in the bonnet, and to show how great is the difference between steel and the lighter material, it may be mentioned that a Ford hood in aluminum weighs just 16 lb. less than the same thing in sheet steel.



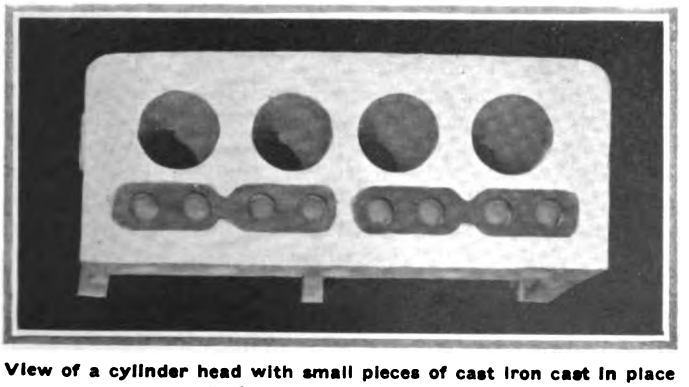
An eight-cylinder aluminum block casting. The heads for this motor will also be aluminum with cast iron valve seats

Cutting Unsprung Weight

After much argument there seems now to be agreement that light axle weight is an advantage from every viewpoint. Obviously the front axle can be made lightest by using the strongest possible material—steel, but this hardly applies to the rear axle. Here we have both strength and accommodation to consider, and the actual axle sleeves must be either steel or reinforced with steel. No other material will withstand the violent shocks for long. Of course, it is possible to make the driving shafts take the whole weight, as was done many years ago, but this calls for very massive shafts. Apart from the sleeves of the axle, however, there is no need for immense strength, and the center part of an axle is designed more to contain the differential and bevels than to act as a bridge between the two sleeves. Of course, it must have strength enough to serve this latter purpose, but the job is well within the power of aluminum, as has been shown by its successful use at this point on many different cars.

This is a debatable point, of course, and many engineers prefer to have a single steel member, either pressing or forging, extending from wheel to wheel without any separate center case. When this style of axle is used the actual differential container is already frequently aluminum as it should be, together with cover plates, etc. An unusual application of aluminum to axle parts has been tried out lately by one of the big axle manufacturers, this being the use of aluminum, permanent mold castings for the shoes of the internal brakes. It is advantageous to have a good rigid support behind the brake facing or asbestos material, and this is given very readily by the aluminum shoe. To provide a working surface for the spreading cam a small piece of steel, already machined, is embodied in the casting and the shoe needs no machining save the drilling of holes for the facing attachment rivets.

On road wheels the hub caps can be aluminum, or very light pressings in brass or steel, and do their work just as well as the all too common heavy brass casting. The wheels themselves are so very delicate a subject that the writer will leave them out of the discussion save for the remark that demountable rims are commonly heavier than the demands of strength necessitate. It is not easy to see how a light metal could be used at all widely in their construction, but weight can be saved by simplicity of design.



View of a cylinder head with small pieces of cast iron cast in place to form the valve seatings

Reducing the Odd Ounces

So far the main units of the chassis have been touched upon and the details left, but, though the big savings of weight will be found in the main parts like the motor, there are many small things on a car which weigh hundreds of pounds altogether.

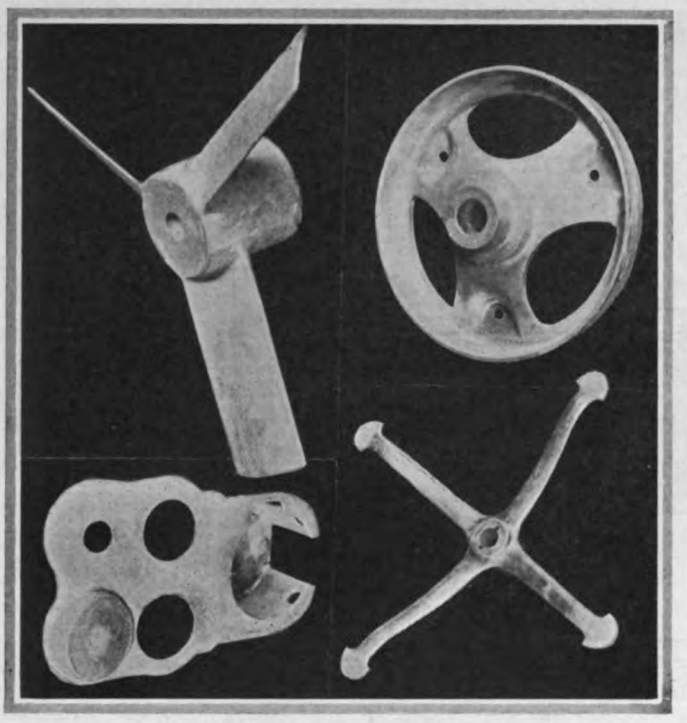
Let us start with saying that except for the radiator and bearing bushings there is no excuse for the use of brass anywhere. Take the radiator cap, for example, and consider a neat design where the cap is a brass casting secured by a quick detachment clip; substituting aluminum would cut out perhaps 6 or 8 ounces.

Again, take all the greasers and lubricators; at present these are not, so far as the writer is aware, made in any material but brass; yet why should they be so heavy? *All* the greasers on a chassis must total to a very substantial number of pounds, and brass weighs more than three times as much as aluminum. What about door handles, switches, control levers, tool box hinges, top fittings and windshield parts?

Then, turning to the body proper, this can be lighter if aluminum is used for the panels, and strength with lightness are combined to a wonderful degree if the whole body is cast. Still if the more usual system is followed it seems reasonable to suppose that much weight could be saved by substituting aluminum castings for some of the concealed parts of the body. Here we normally have heavy ash strapped and bracketed together with iron plates and forgings, and the same strength could be had from aluminum castings with a great weight saving. It would certainly cost more, but so do all novelties till they are brought down to a manufacturing basis.

Better Use of Steel Possible

It would be possible to elaborate this argument for many pages more, but enough has been said to direct attention to the possibilities for weight saving by the substitution of aluminum for other metals. In this way alone it is likely that a 4000-lb. car could be cut down to 3000 or even less, and there is still the chance of further saving by alteration of design to make better use of the steel where steel is the only choice. How we can cut weight in frame and fenders has been suggested in the paper read by A. P. Brush before the Detroit section of the S. A. E. last May, and one might add that a propeller shaft brake is lighter than two brakes on the rear wheels, a Hotchkiss drive is lighter than any other layout,



Sundry small pieces of aluminum which all help to cut the weight

that some forms of springs are lighter than others. No doubt, if lightness becomes the next big boom, as appears very probable, some people will go too far and carry weight saving to the point where convenience or safety begin to be endangered. But even if this should happen we shall settle down eventually with the average automobile a better article from the viewpoint of the millions of people to whom it has become a daily necessity.

War Raises Price

The writer is indebted to The Aluminum Castings Co. for the photographs which have been used for illustration. Most of the aluminum cylinders in use have been cast at the Detroit plant of this company, while the permanent mold work is done chiefly at Buffalo. The Detroit foundry is preparing for a considerable demand for aluminum cylinders and the Buffalo plant is daily increasing its facilities for piston production, the demand for this part having grown at a very great rate. It is unfortunate that one of the effects of the war should have been greatly to increase the price of raw aluminum so that all aluminum parts are now much more costly than they will be when conditions return to normal. Just now the producers of aluminum have their electric furnaces taken to the limit and are still quite unable to cope with the demand; none the less it is expected in many quarters that a drop of 30 per cent may be looked for within a year, and if the prophecy proves to be true the use of aluminum in automobile work will receive much encouragement.

Chasing Aeroplanes with 5-Ton Trucks

PARIS, July 18—Chasing aeroplanes with an American 5-ton truck is a job which delights the hearts of the lads of the Royal Navy operating from the Belgian coastline to bombarded Arras. Early in the present year the British authorities took delivery of a fleet of Pierce-Arrow 5-ton trucks—stock chassis without a bolt or a nut differing from those delivered to clients in America. When they reached England a number of the trucks were fitted with special chrome-nickel steel bodies, the plates being 5/16 in. thick, and each truck received a powerful high-angle anti-aircraft gun. The load was more than the trucks were theoretically designed to carry, being well over 6½ tons, and the recoil of the gun is equivalent to a couple of tons, but this has not prevented them from giving every satisfaction.

Half of Brigade Armored

The first half of the Pierce anti-aircraft brigade has been in active service in France and Belgium for four months. There are eighty-five trucks in the brigade, half of them being armor-plated and carrying a heavy gun, and the remainder having an ordinary body. Since they came across the Channel the trucks have been in service every day and have already accounted for the total destruction of six aeroplanes. After four months' service there has been no trouble in the axles or chassis and not a spring shackle or clip has loosened. This statement is only of value when consideration is taken of the conditions under which the trucks have to work. Unlike the ordinary convoys, these armored trucks have to operate right up to the firing line, many of the journeys being made at night, when not a glimmer of light can be shown for fear of attracting the enemy's fire, and over roads where the artillery had pounded great shell holes, or while the roads were actually being shelled.

Near Hill 60

This brigade got out in time for the great German attack at the end of April and early May, when asphyxiating gas was used for the first time, and the French line was pierced, putting the English and Canadians in a very perilous position. Staff-Sergt. Granville Pollock, an American who volunteered to serve with the English on the Pierce armored car brigade, has supplied a few particulars of the work done by this brigade in that great battle. One of the Pierce armored trucks was stationed by the side of the famous hill 60, near Zillebeck, and within 300 yd. of the first line German trenches. According to a recent statement in the English Parliament, this hill was practically blown out of existence during the great battle.

Asphyxiating Gas and Carbureters

"In order to reach the car," relates Pollock, "we had to make a night trip along the communication trenches as far as possible, then crawl across country lying as if dead whenever illuminating fuses were sent up. The air was so heavy with asphyxiating gases that respirators had to be used most of the time. The driver and gunners of the armored car were found to be in good spirits and resolved to hold the ground and pound the enemy, which they did with deadly effect. Owing to the amount of gas in the air, it was feared that the carbureter might be affected, so every quarter of an hour the motor was started up and allowed to run for a few seconds. In every case a start could be made on the switch. Some of the cars have interesting souvenirs stuck in them: bits of shell and driving bands of copper around the spokes and rims where the 'whiz-bangs' have landed after bursting; some of them have big dents from large lumps of common shell, and one truck has a huge hole as the result of a direct hit. Nevertheless, every truck that came out is still on active service and going strong."

Granville Pollock, who has had war experience in Mexico, and aviation experience in America, slipped across the Atlantic last December with the intention of getting into the aeroplane corps. The Royal Marine Artillery was then forming its anti-aircraft brigade with the Pierce trucks and Pollock was offered the rank of staff-sergeant. He accepted, donned the blue uniform of the British marines, helped to prepare the first batch of armored trucks in England, came across with them, and has been living to the sound of guns ever since.

Passenger cars and commercial cars doing their share of the work at the National Guard Encampment at Hopewell Junction, N. Y.

U. S. Army Needs Motor Transports

Few Trucks at National Guard Encampment Do Excellent Work in Handling Supplies for Commissary Department

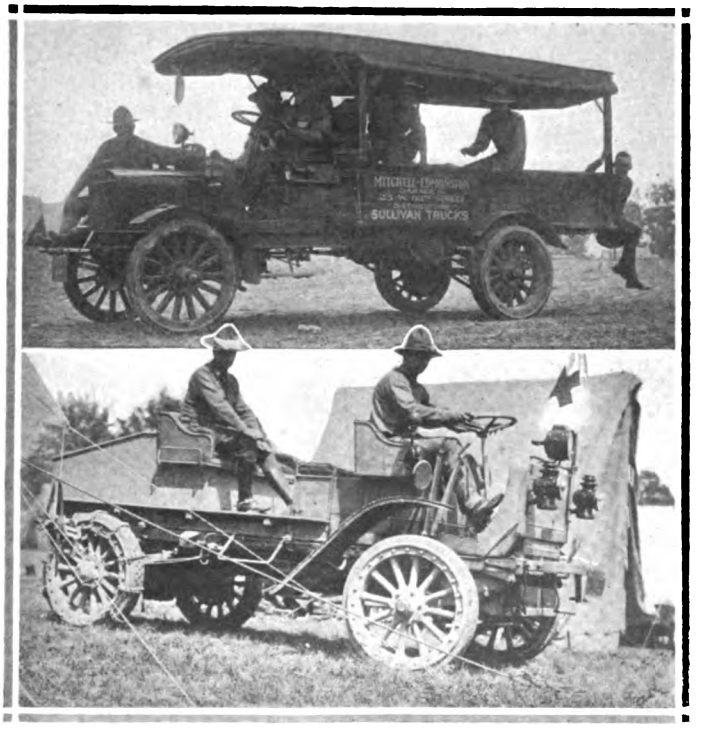
By J. Edward Schipper

WITH the business of war engaging the attention of almost half the population of the earth, it is but natural that the eyes of the people of the United States turn with interest on the military forces of their own country. We are only emerging from the first feeling of stunned surprise which swept over the whole country when the vastness of the scale on which the conflict is waged in Europe struck us with the force of a blow. For years talk of the military preparedness of the great European countries was known to every schoolboy in the country, and yet, when the enormous war machinery was taken from its warehouses and put to the business for which it is intended it could not but cause a feeling akin to dismay in a country in which the war trade is not even a secondary consideration.

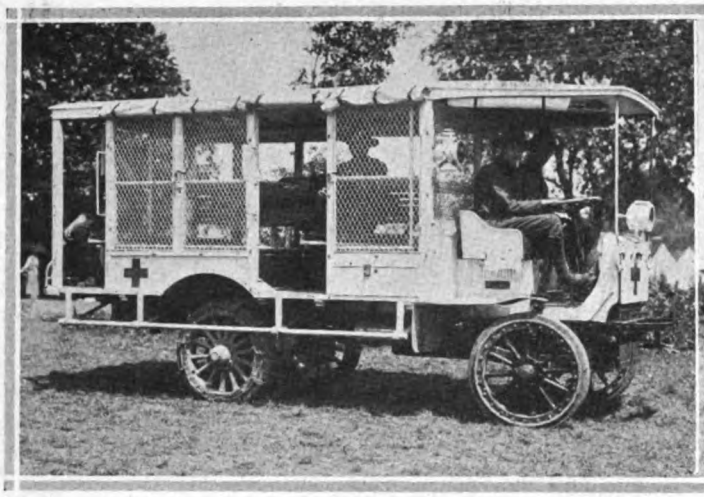
Our strength is the National Guard. That is the expression with which thousands of citizens dismiss the idea that this country would not be able to face in conflict one which has made a study of war for generations. This being the case, it is but natural that the efficiency of the militia becomes of intense interest to the citizenship of the country at large. We have three lines of defense. A small regular army, which is at best but a nucleus; the National Guard, which must in time of war, or at least for the first year or two, be the backbone of our forces, and the volunteers.

Gasoline in War

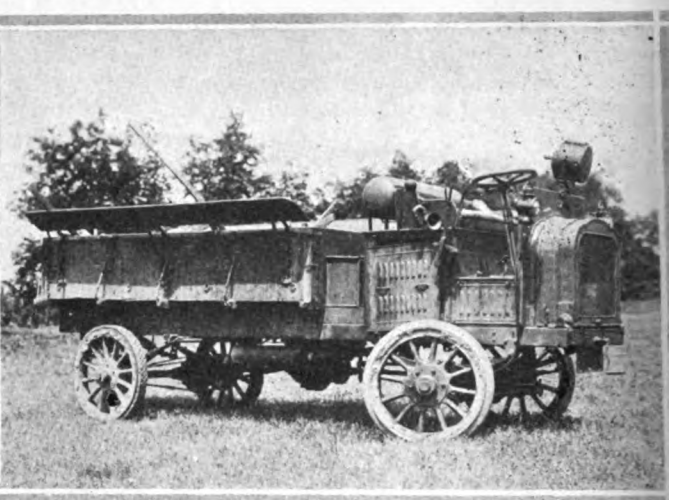
An armed crowd is not an army. An army to be efficient must be well officered and trained, and by arms is not meant guns and ammunition alone, but the thousands of other details which go to make up the equipment of a mobile force. It has been said in Europe that this is a war of gasoline, and in the early stages of the combat where the world was electrified with the stories of quick movements of thousands of troops, this undoubtedly was true. It was gasoline which carried the German armies across Belgium. It was gasoline which carried the French army out of the gates of Paris to oppose the invader and drive him back from the capital of France. It is gasoline wherever quick mobilization becomes necessary. The transportation of heavy guns, of large quantities of ammunition, of machine guns, food, clothing and all the necessities of an army operating some distance from its base of supplies depends on gasoline and the machinery which it drives. Therefore, when talk of training more soldiers and of developing greater efficiency in the National Guard spreads from one border of the country to another, it is the gasoline-driven machinery which we must develop



Sullivan truck and Autocar officers' vehicle used at maneuvers at National Guard encampment at Hopewell Junction



Autocar ambulance similar to the type which went with the Canadian contingent to the front



Flareboard bodies on 1½-ton chassis are most popular for a around army use

along with all the other modern equipment if we wish to put ourselves on a par with other first-class powers.

Throughout the country in various states the National Guard organizations are holding their summer encampments and military maneuvers. Here men who spend the major part of the year in clerical or other sedentary pursuits are taken from their offices and put through the rigid exercises of a military encampment. This week or two of training per year is intended to put the men in touch with the development of military art and to accustom them to the elements of field work which it is not possible to bring out in the armory. It is here that the opportunity arises to demonstrate the advance made in the use of the accoutrements of warfare. It is now that some of the lessons which we learn from the conflict on the other side of the water should be absorbed and kept for future use.

New York Militia Maneuvers

During the last few weeks the army maneuvers of the New York State militia have been held at Camp Whitman, Hopewell Junction, N. Y. During the week of from July 10 to 17 approximately 5000 men were in this camp. These were made up of the Quartermaster's Corps, which acted as a central supply depot, and four regiments. The Seventh, Twelfth, Sixty-ninth and Seventy-first. In addition, there were three troops of cavalry, composed of a squad of the Second United States cavalry regulars and Squadron A; a hospital corps and four companies of regular infantry.

The work of this body of men is of particular interest, since the New York State militia make up an entire division in the army, and is supposed to be as efficient as any state militia in the country. The work of the officers and men individually can be dismissed as enough is said when it is stated that they are all members of crack organizations and can be relied upon to go through the manual of arms and field maneuvers with great éclat. In point of equipment, however, outside of a few machine guns and modern small arms, a wide chasm exists between what our men had and what would have been a part of the organization of one of the up-to-date foreign forces.

For the entire force of 5000 men but twelve motor trucks were supplied, and of these only five were owned by the organizations in camp. Four of the trucks were owned by the Quartermaster's Department and the fifth by the Seventh Regiment. The other trucks were merely loaned by companies for demonstration purposes or hired from civilian owners. A few of the officers brought their private passenger cars, but there was no organized arrangement of these. There were a few motorcycles used by the provost guard, but no motorcycle scouting corp was on hand. The

Some of the roads at the maneuvers resembled what might expected in campaign work

camp kitchens were pulled by mules and horses, as were camp equipment and supplies of the men. If the army had to make a forced march of 48 hours across country would have been at the mercy of the said mules and horses

Motor Trucks Necessary

Of course this was merely a practice camp, the main p pose being to train the men, but there is no doubt but t we should go farther than this in our maneuvers if t are to be of value in bringing the citizen soldiery of country up to a state of such preparedness that should arise they would be able to take immediate advantage the lessons to be learned from the fighting on the other s When we learn that one of the belligerents has for the year or two been arranging the motor trucks of one of largest concerns so that at a moment's notice the bodie peace times may be removed and guns and armor which already been prepared fitted instead, we get a small ink of the detail to which attention has been paid in fitting mobile equipment for possible war times.

Although consisting of but 5000 men, the New York S militia did not have a sufficient number of trucks to ha

the situations which develop in camp. The trucks attached to the Quartermaster's Department were not sufficient to meet the requirements of bringing in provisions for the men and horses. Each regiment is allowed, by army regulations, four escort wagons. These are supposed to take care of the needs of the regiment. Generally, each of these wagons is hauled by four horses or four mules, and they have the advantage of being able to go through practically any kind of country. In the short-haul work between the last possible stretch of road for motor vehicle and a camping spot they are indispensable. In other words, they fill the gap between the motor truck and the pack mule.

Want Motor Equipment

Officers and men on every side stated their belief at the encampment in the value of a motor transport service. In fact, in view of what it has done in other countries, its value cannot be denied. The armored car, the motor camp kitchen, the scout car, the motor tractor for heavy guns, the motor-equipped wireless telegraph, field telephone, field observation post, searchlight service, ambulance service, medical supply service, ammunition supply and numerous other gasoline-driven vehicles are a matter of life and death to the fighting men of Europe. It is time that we, in training our soldiers, should teach them the use of these modern implements of warfare as much as we do the use of the machine gun, automatic revolver and developments in actual armament.

Of the four regiments in Camp Whitman only one, the Seventh, had motor trucks in addition to the four army transport wagons and sixteen horses. This regiment had five trucks, a 1½-ton White owned by the regiment, a 2-ton Pierce-Arrow and a 2-ton Mack hired from civilians at Newburgh, a 1½-ton Sullivan and a Morton tractor which were demonstrated at the camp. The Morton tractor was tried out, hauling five of the regular army transport wagons at a time over all kinds of roads, and with its large steel-studded tires was able to secure good traction and made a favorable impression.

In the hospital corps there were three 2-ton Autocars on demonstration. One was a two-seated officers' car used by the chief surgeon, another an ambulance and the third a searchlight truck. The ambulance was of the same type as that furnished to the Canadian contingent which left for the scene of war last year. It has stretchers for six wounded and can carry six prone or eight sitting.

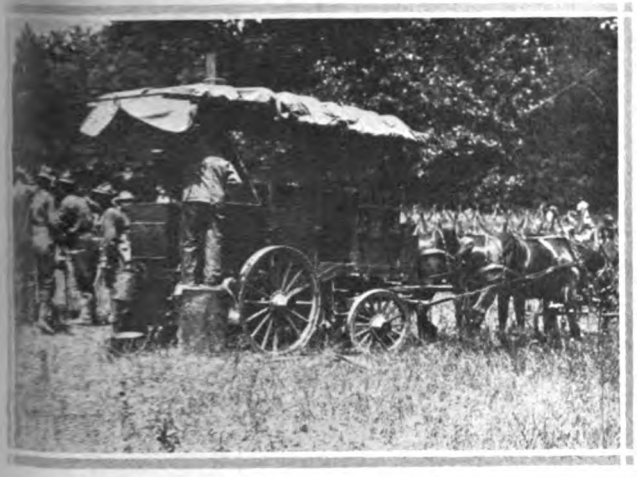
The Motor Searchlight

The searchlight truck is provided with a direct connected generator driven by a motor which is the same as that supplied for power purposes for the car. A hand cart carries two reels of wire, each ¼ mile long, permitting the searchlight to be wheeled a half-mile away from the source of power. In this way light can be played on the enemy from over the brow of a hill while the power plant is safely hidden beneath the shelter of the slope. The generator is operated at 110 volts, 45 amperes, and the lamps are of 5000 candlepower.

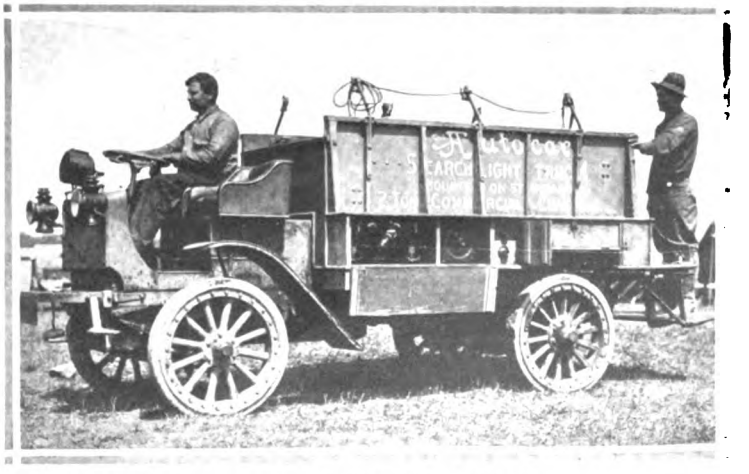
The searchlight truck and the ambulance were the only two bright spots which showed modernness or any tendency toward that state in the motor equipment. The 1½-ton Whites which were owned by the Quartermaster's Department and the Seventh Regiment have come to be old standbys and proved themselves to be of great use three years ago in the Connecticut maneuvers. Beyond this the motor equipment did not exist, unless the few motorcycles and privately owned touring cars which, it must be admitted, were of great utility, be included. The equipment which would enable the soldiers to practise moving large bodies of men over great distances was lacking, as was the motor-driven trench-digging apparatus and the various other up-to-date equipment which has come to be regarded as essential.

1½-Ton Truck Favored

Nowhere was anything heard against the use of motor-driven apparatus wherever it was possible to carry it. It is the consensus of opinion that the 1½-ton truck is the best all-around vehicle because it is fast and light, comparatively speaking. It does not become readily bogged, keeps up with the line of march readily, and can be converted to practically any use which the needs of the moment demand. The principal uses of the truck are in transporting supplies from the railroad base to the nearest accessible point to camp, and where large bodies of men are to be moved across country there is no doubt but that the use of motor vans, wherever the roads permit, would greatly increase mobility.



The camp kitchens were of the horse-drawn variety, these being handy for short marches



Searchlight apparatus on Autocar truck which can be hauled ½ mile away from source of current

Connecting-Rod Design for V Motors

Advantages and Disadvantages of the Side-by-Side Construction and the Forked End Rod—Why the Separate Arm Type Is Not Adopted—Movement of Rod Ends on Bushings

By Chester S. Ricker
Consulting Engineer

AT the February meeting of the Indiana Section of the Society of Automobile Engineers the question of connecting-rod design on eight-cylinder V motors was discussed. There were three types of motors mentioned: those with separate rods side by side on a common crankpin, those with a yoked-rod end on one side and a tanged end on the other rod which fitted inside of the yoke and took bearing on the yoke rod bushing; and lastly those in which a separate rod of shorter length was used and which bore against a special pin located on the side of the other rod.

The first of these constructions is exemplified in such eight-cylinder motors as are built by Herschell-Spillman and Buda companies. The second construction seems to be the most popular and is standard construction on Cadillac, Cole, King Ferro and Detroiter eights. The third form was used on the Schebler twelve-cylinder motor that was built about seven years ago.

The side-by-side construction has nothing against it practically but does have the disdvantage that it necessitates the offsetting of the two-cylinder blocks so that the axes of the opposite cylinders will not pass through the same point on the crankshaft. This adds to the length of the motor slightly and does not make the motor absolutely symmetrical. It has the advantage that it permits the same adjustment of the rods after long usage just as one has on an ordinary motor of the vertical type.

The forked-end rods make for the shortest eight or twelve V-motor as the axes of the opposite cylinders are directly in line and the two connecting rods are likewise in the same line. The usual construction is to have the forked rod carry the bushing which runs on the crankpin. This bushing is in most cases made from a hard bronze and lined with an anti-friction metal. The rod from the opposite cylinder has a bearing on the outside of this bushing, frequently the former is case hardened steel and the latter hard bronze. The object has been to give this bearing the same kind of surfaces as have been found satisfactory on piston pin bearings. In the S. A. E. meeting referred to one person stated that the movement of the connecting-rod end on this bearing was no more than on an ordinary piston pin. The purpose of this article is primarily to show just how much that movement really is on V motors and also to consider the reasons why the third type of connecting-rod has not been found satisfactory and has not been adopted on any of the most successful and up-to-date motors.

Piston-Pin Movement

It has not been customary to provide adjustment for piston pin bearings, although some manufacturers, notably Apperson, have done so for fifteen years. The question is, why have most manufacturers not done so? The connecting-rod does not revolve on this bearing b merely oscillates and for this reason do not move either rapidly or to any gre extent. That is why the wear on pist pins is so slow and why no adjustment usually considered necessary.

The movement of the piston pin e of the connecting-rod with reference the piston can easily be determir trigonometrically. It varies with length of the connecting-rod and stroke. If we express these variables a single factor we can readily comp the total angle through which the up end of the rod moves. The maxim angle B_p formed between the connecti rod and the vertical or axis of the cy der is determined immediately by formula $\frac{R}{L} = \tan B_p$. The angle B_p

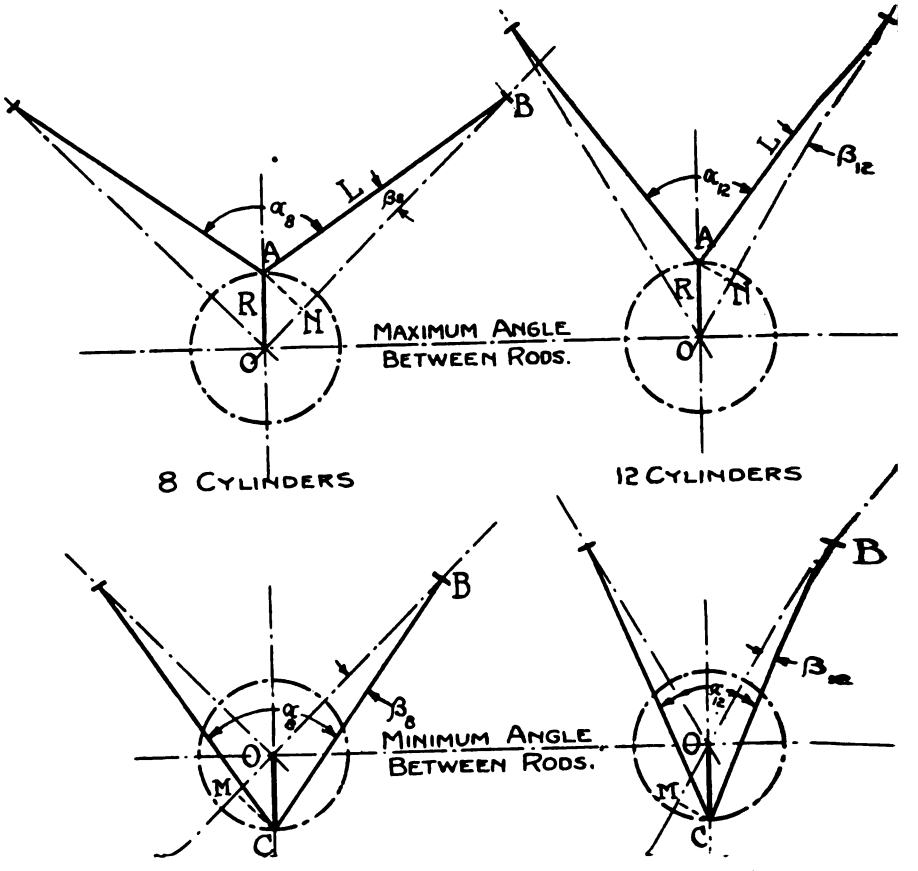


Fig. 1—Maximum and minimum angular positions between the connecting-rods i eight and twelve-cylinder motors

been computed for several values of $\frac{R}{L}$ in the appended table. The total or maximum movement of the rod end with respect to the piston is just twice B_p. This has also been computed and is found under $2B_p$. The values of R, which represents the crank length and L which is that of the connecting-rod are both transferred to an abstract quantity by using the ratio so motors of any size may be checked up from this table which is between the limits of 1:4 and 1:5. From this it will be seen that 28 deg. 6 min. is about the maximum angle in good practice and that it may be reduced to 22 deg. 36 min. if the connecting-rod is made long enough.

Movement of Rod Ends on V Motors

The computations made in these tables are not confined to the eight-cylinder motor but include data on twelve-cylinder motors with the cylinders at 60 deg. A number of such motors are on the road so that this information will not be amiss at this time.

In the accompanying diagram, Fig. 1, the maximum and minimum angular positions between the connecting-rods in both eight- and twelve-cylinder motors are shown. In the table which accompanies this article the maximum and minimum angles are not tabulated as they do not have anything to do with the computation of the difference between the maximum and minimum angles. In the diagrams the angles B_8 and B_{12} have been computed because it can be easily proved in the following tabulation that the difference in angles between the rods is equal to four times B_8 or B_{12}. In the table it will be seen that maximum movement of the rods on an eight-cylinder motor varies from 40 deg. 44 min. to 32 deg. 32 min. On the 60 deg. twelve-cylinder motor it is considerably less, varying from 28 deg. 44 min. to 23 deg. 0 min.

Computations

$$\frac{A-N}{R} = \text{sine } 45°. \quad A-N = .707\ R$$

Hence,

$$\text{sine } B_8 = .707\left(\frac{R}{L}\right)$$

After computing B_8 it is easy to find that

$$\alpha \text{ max.} = 90° + 2B.$$

Similarily it may be proven that

$$\alpha \text{ min.} = 90° - 2B.$$

The difference

$$\alpha \text{ max.} = \alpha \text{ min.} = 4B.$$

For the twelve-cylinder motor

$$\frac{A-N}{R} = \text{sine } 30°. \quad A-N = .5R.$$

Hence

$$\text{sine } B_{12} = .5\left(\frac{R}{L}\right)$$

After computing B_{12} you find that α max. for twelve-cylinder motor will equal $60° + 2B$, and similarly α min. $= 60 - 2B$, making α max. $- \alpha$ min. $= 4B$.

From the tables included it will be seen that the maximum movement of the rods on an eight-cylinder motor is between 44 and 45 per cent greater than that of the piston pin. On the twelve-cylinder motor this is much less varying from 2.5 to 1.75 per cent. Hence it is evident that the twelve-cylinder motor practically duplicates the piston pin bearing conditions at the big end of the forked rod.

Assembling the Forked Rods

One of the best-running motors of the eight-cylinder, forked-rod variety has the rods assembled in the following manner: Two of the forked rods are attached to the pistons in the first and fourth cylinders of the left hand block. The other two forked rods are attached to pistons in the two middle cylinders of the right cylinder block. In this manner the centrifugal effects upon the crankshaft and the balance of the motor is equalized, so it is claimed. This is the construction of the latest Northway

(*Continued on page 237*)

Group of S. A. E. members in attendance at the meeting of the nomenclature division of the standards committee in Detroit

Standardizing Names of Parts

S. A. E. Starts Scheme for Universal Nomenclature—Will Save Time and Money in Replacement Work

IT has long been an ideal of the S. A. E. to determine a standard nomenclature for all the parts of an automobile so that confusion between the owner who wants the part, the dealer who has to fit it, and the manufacturer who supplies it may be avoided. At present the amount of time and money wasted every day by the difficulty of understanding what it is that the customer is writing about is immense, but to discover a way of cutting out redundant names has proved very much more difficult than anyone would imagine it could be.

Some Data Collected

The nomenclature committee has labored without producing any very tangible results, but the work done has been sufficient to demonstrate the great importance of the subject, and enough data have been collected to enable a fresh start to be made along a sounder line.

With this idea in view a meeting of sundry engineers and service men was called at Detroit last Friday, July 30, and the meeting was presented with a list of suggested names for a majority of the parts in a gasoline engine. Coming straight to detail these were taken item by item and the fitness of each term thrashed out. At the end of three hours the fifteen men present had agreed upon the names of some twenty simple parts only, and in one or two cases half an hour or more was occupied in the discussion of a single word.

Small Committee and Salaried Secretary Proposed

This sufficing to show the real practical difficulty of pleasing the ideas of everyone, Howard E. Coffin, vice-president Hudson Motor Car Co., proceeded to explain that the Society as represented by the Council thought the subject too difficult for handling by a committee. He pointed out the extremely small amount of progress made in a whole morning's work and said that the new idea was to create a small committee and provide a competent, salaried secretary who would spend a year or two on nomenclature work exclusively, taking constant mail votes and calling upon the committee to an extent which the members would not feel made an excessive demand upon their time.

There is not an owner of an automobile, a dealer or a manufacturer who would not feel the benefit of a successful conclusion of this work, and the enthusiasm of the service men at this preliminary meeting showed in unmistakable terms what it will mean to them.

That the men present were representative of all classes of the industry and all types of chassis may be seen from the list following. Representing the S. A. E. were Howard E. Coffin, K. W. Zimmerschied, Coker F. Clarkson and A. C. Woodbury, who has collected the data which the meeting discussed by searching manufacturers' replacement parts lists. Representing the industry were: E. E. Sweet (Cadillac); H. W. Booth (Dodge Bros.); H. H. Barrows (Maxwell); H. W. Drew (Marmon); J. S. Smith (Moline); R. E. Marston (Packard); G. S. Mather (Paige); W. B. Stout (Scripps-Booth); E. J. Chase (Studebaker); E. W. Vultrie (Hudson); C. W. McKinley (Overland); A. L. Clayden (THE AUTOMOBILE).

Half an Hour on One Subject

To give an example of the sort of difficulty which has to be overcome, one-half hour was spent without any very definite results in discussing what was a bearing and what was a bushing and what can be done with the nomenclature of bearing caps, carriers, housings, retainers, cages, etc. Water pipes and passages are another trouble, for there is an infinite variety. They may be top or bottom pipes, inlet or outlet manifolds, etc. Also a pipe which is an outlet from the cyl-

...der jacket is an inlet to the radiator, and vice versa, which ...gives a magnificent opportunity for confusion. The main ...idea in developing this works is to divide the whole car into ...groups and classify under a series of group headings. Be... the suggested general divisions and part of the ...of Group 1, which shows the idea of the pro... it is intended to follow; it must be understood ...are dealing with suggestions only, though it is ...that another few months will show some real ...difficulty is a natural effect of the wonderfully ...of the automobile industry and it is character... industry to get together and straighten out the ...rms which they have created individually.

Group 1. Cylinder—Includes all parts usually assembled therewith, such as studs, valve caps, wire brackets, gaskets, water header.

Group 2. Crankcase—Includes all parts usually assembled therewith, such as studs, bearings, gaskets.

Group 3. Crankshaft—Includes all parts usually assembled therewith, such as timing gear, flywheel, oil connections.

Group 4. Camshaft—Includes all parts usually assembled therewith, such as timing gear, oil pump gear, pressure pump cam.

Group 5. Connecting-Rod and Piston—Includes all parts usually assembled therewith, such as bearings, shims, pin, rings.

Group 6. Valve—Includes valve-lifting mechanism above cam, tappet, spring, etc.

Group 7. Ignition Drive—Includes parts used to drive ignition devices, up to and including coupling.

Group 8. Auxiliary Drive—Includes parts used to drive electric lighting and starting system, tire pump, etc., up to and including coupling.

Group 9. Water Pump.

Group 10. Oil Pump.

Group 11. Starting Crank.

Group 12. Fan—Includes bracket, drive pulley, belt.

Group 13. Intake Manifold—Includes cylinder gaskets, nuts.

Group 14. Exhaust Manifold—Includes cylinder gaskets, nuts.

Group 15. Fuel Pressure Regulator.

Connecting-Rod Design for V-Motors

Methods of Timing Eight-Cylinder Motors

(*Continued from page* 235)

...product in which experiments have been ...made with the forked rods all on one ...side. This has been found the most de...sirable combination.

Offset Connecting Rods

In order to illustrate the inherent disadvantage of the third type of V motor connecting-rod design the writer has drawn an accurate diagram, Fig. 2, showing the various positions of the pistons in the two cylinders at different points in the stroke. From this it will be clearly seen that the right hand piston which is attached to the short connecting-rod does not move in the same manner as does the normal piston. The path of the lower end of the short connecting-rod is an ellipse instead of a true circle. As a result the piston movement in the right hand cylinder has an entirely different characteristic from that in the left-hand side, in fact it is not like that of any conventionally connected motor. For example it reaches the lower dead center at about 160 deg. movement of the crank instead of 180. It has a considerably longer stroke than the left hand cylinder. This difference in characteristics should cause valve trouble unless a special camshaft were made and designed for this side of the motor. On account of the different timing necessary and the difference in stroke it probably will give a greater or less amount of power and so upset the balance of the motor. The rotational balance is probably very bad compared with either of the other types of connecting-rods so that we may expect to see much worse vibration from this type of motor than from the standard motors of any type.

Twelve-Cylinder Possibilities

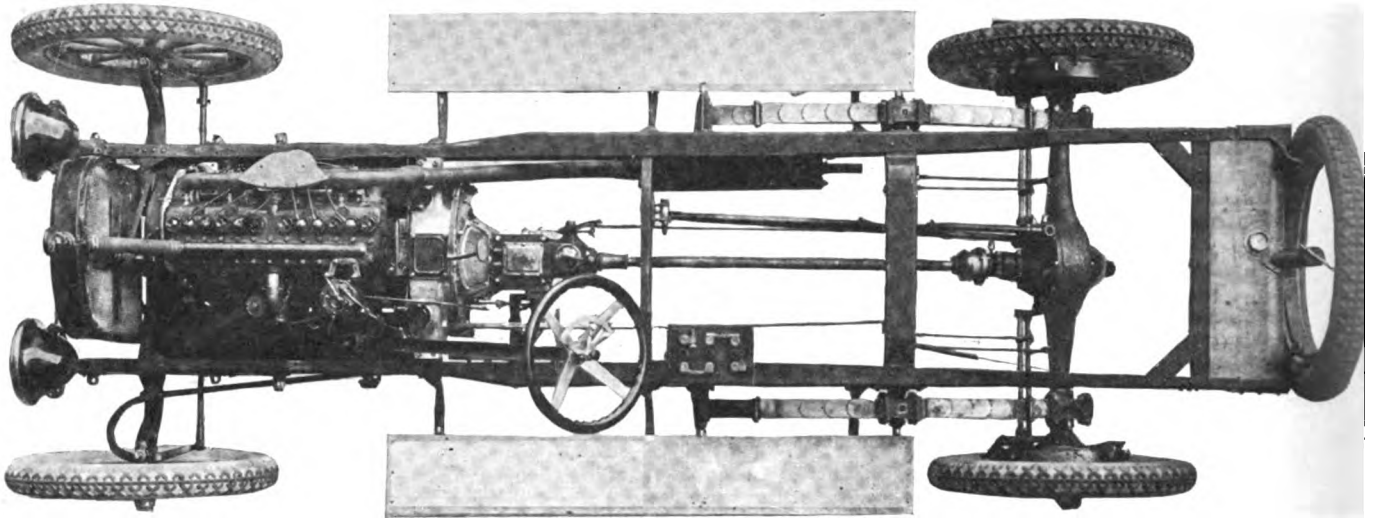
As to the power obtained and the smoothness of operation that may be expected from the twelve there is little to be said. The eight is good enough in performance and if it were not for some other reasons, sales or mechanical, there ought to be no reason for the twelve-cylinder motor's existence. The writer was of that opinion until the other day when he saw a twelve-cylinder, 60-deg. motor with 2¾ by 4½ in. cylinders. It was not a question of operation with that motor that made a decided impression but its accessibility as compared with the eight. Both blocks of cylinders were of the "L" head design. Two camshafts were used so that the valves might be placed on the outside of the job instead of inside of the "V." This made the most accessible motor of the "V" type that the writer has ever seen whether eight or twelve. This was the first commercial design of the twelve-cylinder motor that the writer has ever seen although he understands that there are two or three others on the road, being thoroughly tested out by companies of the highest reputation. It is quite possible that one or more will be announced this fall.

V-Motor Timing

There are two general ways of timing the eight-cylinder motor as practiced today. One is to fire the diagonally opposite cylinders; for example: 1/8, 3/6, 4/5, 2/7. The other is to fire opposite cylinders, 1/5, 3/7, 4/8, 2/6. This counts the cylinders from 1 to 4 in the right-hand block and 5 to 8 in the left-hand block, starting at the forward one in each case. The first firing order can easily be remembered in either one of two ways: first, the sum of the numbers of each pair of cylinders is nine. For example 1/8 equals nine, or 2/7 is nine. The other way of remembering it is by drawing the diagonals from the cylinders firing in consecutive order. Thus the diagonal from 1/8 passes through the center of the diagonal from each of the other three pairs, 3/6, 4/5, and 2/7. In other words they have a common center. Try it and see. The same rule holds good for the twelve-cylinder motor. For example the firing order of one twelve is 1/12, 5/8, 3/10, 6/7, 2/11, 4/9. The sum of the cylinder numbers in each pair is 13. Here again the cylinders fire diagonally, as mentioned above, and they may be checked up in the same manner.—CHESTER S. RICKER.

12,000 Cars Estimate for Arizona

PHOENIX, ARIZ., July 31—It is estimated that more than 12,000 automobiles will be registered in Arizona during the year 1915. This estimate is based on the fact that during the first six months of the year there were 5851 automobiles registered. Mining and industrial conditions generally are highly satisfactory.



Westcott six chassis showing new Continental power plant with Warner disk clutch and three-speed gearset

Westcott Concentrates on Two Sixes

New Edition of the Seven-Passenger Model and a New Small Six Similar in Design— Power Plant and Body Lines Entirely New

FOR 1916 the Westcott Motor Car Co., Richmond, Ind., offers a new edition of the six-cylinder, seven-passenger, model U-50, at $1,595, and a brand new small six like the other in appearance and design, at $1,295. Thus, the four of 1915 has been discarded. The U-50 now is called the model 51 and is selling at a price only $10 higher than the 1915 car, but with considerably more than that amount of improvement.

The whole car has been gone over and where a betterment could be made, while keeping the weight, appearance, strength, etc., to the company's standards, it has been done. The power plant is new, the body also, the springs are stronger and longer, the radiator has better lines, the frame has been altered, the wheels made stronger, the tire size increased, the wheelbase increased, and any number of other changes made.

Power Plant Entirely New

The Westcott model 51 power plant is entirely new, being composed of a Continental 3½ by 5¼ motor instead of that used in 1915, a Warner, Muncie, disk clutch instead of a cone, and a Warner three-speed gearset instead of that employed previously. These changes have resulted in more power, the old motor having dimensions, 3 by 5, better throttling, because of the new type of clutch and more efficient all-around performance.

There is nothing in the power plant which is out of the ordinary. The motor has its L-head cylinders cast in block with the exhaust manifold on the right, with the valves and the carbureter on the left, feeding through cored passages. The carbureter is a new type Rayfield. Directly behind the carbureter is a Stewart vacuum feed tank bolted to the cylinder casting by a small bracket. The Delco cranking, lighting and ignition unit is on the right at the rear so as to start the motor through the toothed flywheel and in front on the same side is a Stewart tire pump driven from the water pump shaft. The tire pump is added equipment for 1916. This model Continental motor uses a three-bear crankshaft with bearing sizes as follows: Front, 2 3 diameter by 2⅞ long; center, 2 7/32 by 2½; rear, 2¼ b It drives a three-bearing camshaft through helical gear The camshaft bearings have the following dimensic Front, 2 19/32 by 1½; center, 2⅝ by 1⅛; rear, 1½ by the first dimension given being diameter. There is notl of unconventional design about any of the other parts, as pistons, rods, etc. The former carry three rings, 3/1 wide. Valves are 1 11/16 in. diameter.

The oiling system is the same as in other large C nentals—force feed and splash using a horizontal plu pump driven from the camshaft by eccentric action for oil through copper pipes to the timing gears and rear bearing. The oil drains back to the oil pan where it is for splash for the cylinders and pistons.

In the power transmission system there is a tubular fitted with Spicer joints and a Timken rear axle with sp bevel gears, these members having been used in the 191 in practically the same form. There has been a slight ch in the torque member which now has a steel hanger in instead of one made of malleable iron.

Cantilevers of Chrome-Vanadium Steel

The cantilever rear springs, while they are of the design as in the 1915 car, now are made of chrome-vana steel instead of carbon steel in order to obtain stronge struction. The front springs are unchanged.

The frame has been altered in the rear so that it ex beyond the rear cross-member so as to form a gasoline support. In the older models brackets were riveted frame and the tank suspended from the brackets. Th construction is much stronger than that previously use there is not as much strain on the frame cross-member. the tire carrier is incorporated in the frame extensio the gasoline tank now has a gooseneck filler so that will be no inconvenience in pouring gasoline even f

large container. This is a small feature of convenience which is indicative of the thoughtful design characterizing the cars.

The steering post is of Gemmer make for 1916, the fenders are heavier and slightly broader, the foot control pedals have been made easily adjustable and all the sheet metal work on the car securely bolted so as to prevent rattling.

Wheelbase 1 In. Longer

The rear wheels are stronger and in order to insure rigidity alternate spokes are bolted to the brake drum. The wheel rims are now Firestones instead of the straight side, one-piece variety, and carry 35 by 4½ tires instead of 34 by 4, the tires being Kelly-Springfield non-skids all around. The wheelbase now is 126 in. instead of 125.

Body Entirely New

The body is an entirely new job, larger than the previous one with additional equipment, and with better lines. In order to get a better slope from cowl to radiator the latter has been made 1 in. narrower and 1 in. higher and there has been a rounding out of the sides just back of the hood. This rounding out has been extended to the rear of the body.

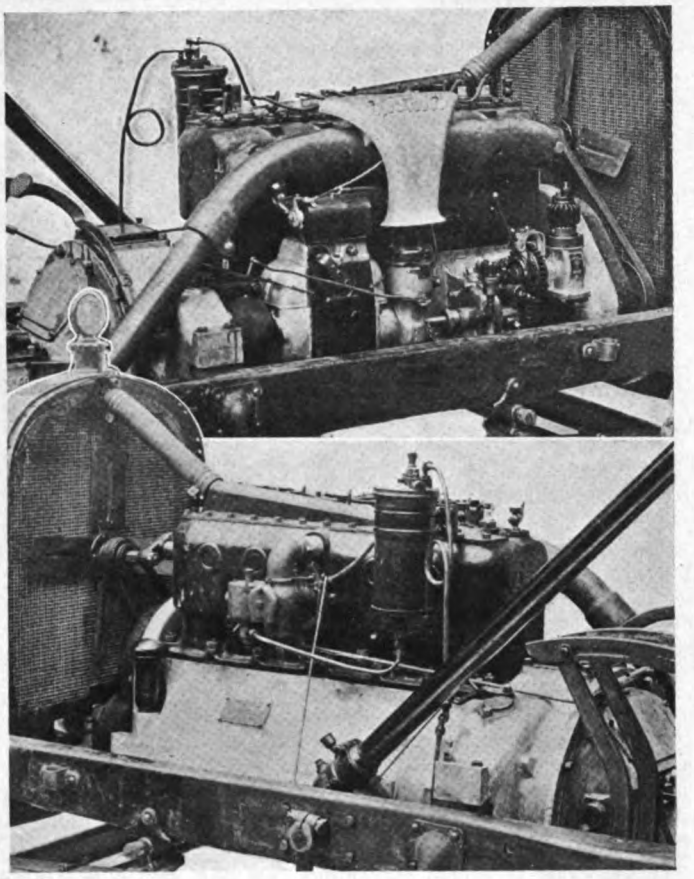
In order to do a better job of the divided front seats the backs of these now run into the body moulding which is of black wood. The seat moulding at the top also is of this wood and at the junction of seat and body moulding, the two are gracefully curved into one another. These seats now are hollow underneath, so as to accommodate the two extra folding chairs which when placed away may be covered by a neat flap. Also when the extra seats are not in use the floor slots are completely covered by carpet.

While there has been a tonneau light in the back of the right front seat in the older models, the 1916 cars have this, and in addition, a cigar lighter in the back of the left seat.

Under the rear seat there now is an easily-removable plate so that when the rear seat cushion is removed it is an easy matter to get at the differential housing to fill or drain it.

The upholstery is of new design and is called straight piped. In this the leather is formed into folds which are stitched, thus doing away with buttons and making a more sanitary method. The upholstery now is of bright leather instead of dull.

Two views of the Westcott six-cylinder, seven-passenger touring car for 1916



Both sides of the Westcott six power plant for 1916 showing mounting of the Delco electric system

The cowl has been changed so as to accommodate the new instruments necessary with the changes in the power plant. There now is an oil pressure gage instead of a sight feed, and a new ammeter.

In the equipment there is a new type of windshield with overlapping halves and a Boyce Motometer, which was not used on the 1915 cars.

The top is a new one-man type with the rear portion of one piece with an oval window, and extending part way around the body. The Jiffy curtains furnished are fitted with springs to prevent flapping.

Small Six Similar in Design

To describe the small six would be to repeat the information just given relating to design. The only differences between the large and small models are in the wheelbase, which on the latter is 120 in., the tires, which are 34 by 4, the motor, which is 3¼ by 4½, but of the same make and design, and in the body capacity and equipment. The body is a five-passenger and is not fitted with a cigar lighter, nor is a Motometer given.

—

Dunwoody Adds Automobile Course

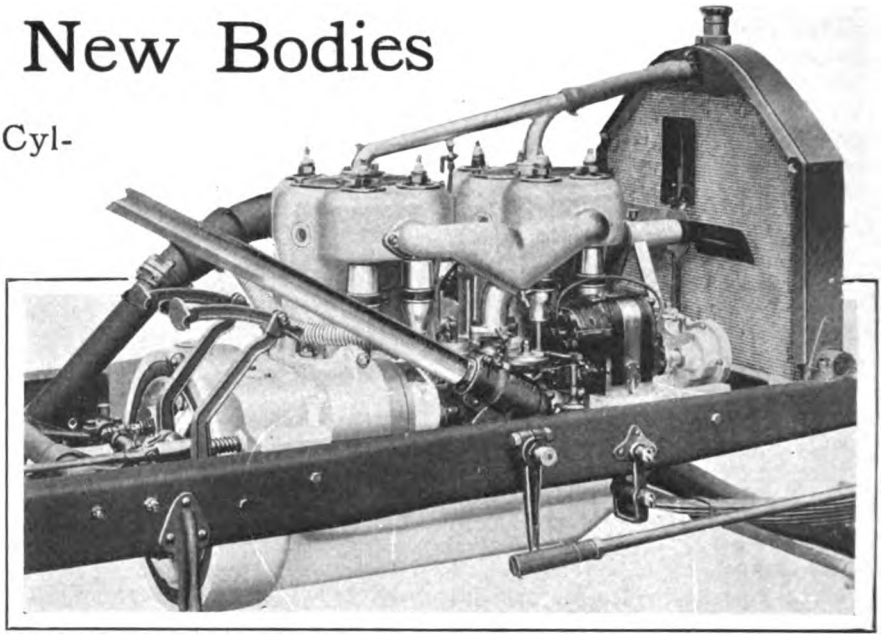
MINNEAPOLIS, MINN., Aug. 1—The Dunwoody Institute, endowed at about $2,000,000, has added automobile mechanics and is erecting a garage and shop adjoining the main building. It is the plan to negotiate with garage proprietors to take over the graduates as fast as they are turned out. The school plans to raise the standard of motor car mechanics. A course for inexperienced men will be two years of theory and practice. For a diploma a graduate must spend a satisfactory year as an employee.

Stutz Features New Bodies

Mounted on Two Four-Cylinder Chassis

IMPROVEMENT of body design will strike the average observer as the most noticeable change in the line of the Stutz Motor Car Co., Indianapolis, Ind., although there have been minor chassis changes of interest. The new bodies are mounted on four-cylinder chassis only and these are the same in every respect with the exception of the wheelbase, one being 120 and the other 130 in. as in 1915.

There are three body styles for the smaller car as follows: Bearcat at $2,000, roadster at $2,100 instead of $2,000 and Bulldog at $2,250. On the 130-in. car there are two standard bodies, a newly-designed four-passenger Bulldog special having a double cowl and selling at $2,550 and a four-passenger touring car at $2,300 instead of $2,275.



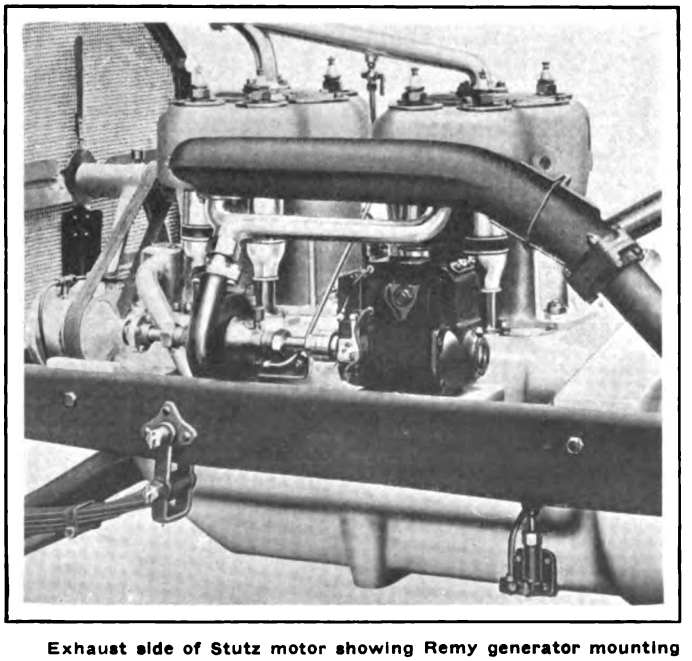
Intake side of Stutz power plant for 1916 showing mounting of the Remy starting motor and Stromberg carbureter

While the general features of Stutz design are generally known and the changes made are of no radical nature, admiration attaches principally to the new bodies, especially the Bulldog special. This has an unusually low-hung appearance with the passenger seats lower than usual. The whole body is a neat streamline job with almost a straight line from windshield to radiator, flush doors and symmetrical sides.

Side Lamps Eliminated

The general smoothing out of the front of the car has been assisted by eliminating dash lamps and using headlights with dimmers. Instead of using wood strips to finish off the upholstery, the new body uses aluminum moulding which not only makes a better appearing finish but is more serviceable.

The tonneau cowl has two compartments, one being designed for carrying a lunch kit and the other for two Thermos bottles which are part of the equipment. The cowl material is Circassian walnut.



Exhaust side of Stutz motor showing Remy generator mounting

This car comes regularly equipped with wire wheels and Silvertown cord tires which add to its racy appearance, a new type of windshield which is not as high as the ordinary type and a searchlight.

The other touring car body, while it has the same general lines as the Bulldog special, has low individual front seats which make front seat riding extremely comfortable. There are only two doors and these are in front so that tonneau passengers must pass through the aisle between the front seats in order to get to the rear seat. The elimination of the doors in the rear and the removal of dash lamps, as in the special, has offered the designer a means of getting a well-rounded out streamline body with no eccentric design and yet giving a low, rakish appearance. The upholstery in this model is finished as in the other and the equipment is the same with the exception of the wire wheels, tires and Thermos bottles.

Roadster Now Fully Equipped

The roadster now comes fully equipped and this is largely responsible for the increase of $100 in the price. The body has been improved by bringing the seat upholstery flush with body sides and increasing the length of the cowl line. The back of the seat has been rounded more, and as in the others, the dash lamps have been abandoned. There now are doors on either side instead of on the left side only as in the 1915 model.

In the Bearcat model there have been no apparent body alterations.

The most important mechanical change is the enlarging of the oil receptacle in the crankcase so that it now holds 2½ gal. instead of 1½, this having been made so that less oil changing is needed. The crankcase has been increased in size and at the same time it has been given a more symmetrical appearance.

Stutz springs, while they are of the same design as heretofore, semi-elliptic all around, now are made of alloy-steel instead of carbon-steel in order to obtain greater strength and longer life.

Accelerator pedal operation is facilitated by the addition of a heel pocket in the front floorboard. In the equipment changes made on all models, there is the substitution of Hartford racing type shock absorber for the automatic type, and also the fitting of a Motometer to the radiator.

Stutz cars for 1916 in their general makeup comprise a

four-cylinder, pair-cast T-head motor, a leather-faced cone clutch and the characteristic Stutz rear axle gearset which has been used by this company since its inception. Tires are 34 by 4½ on all except the Bulldog special which uses 33 by 5. As in the past all Stutz cars use right drive and right control and it is one of the few makes adhering to this construction.

The motor is a 4¾ by 5½ with three-bearing crankshaft and camshafts.

The two latter operate roller type push rods, and the valves, which are tungsten steel 2¼ in. in the clear, have the mechanism inclosed by individual housings. The camshaft drive is by helical gearing. There is nothing unusual in the piston or rod construction.

Lubrication is by force feed through a hollow crankshaft, carburetion by a Stromberg model H and ignition by Bosch high-distributer magneto on all models except the touring car which uses Bosch single point.

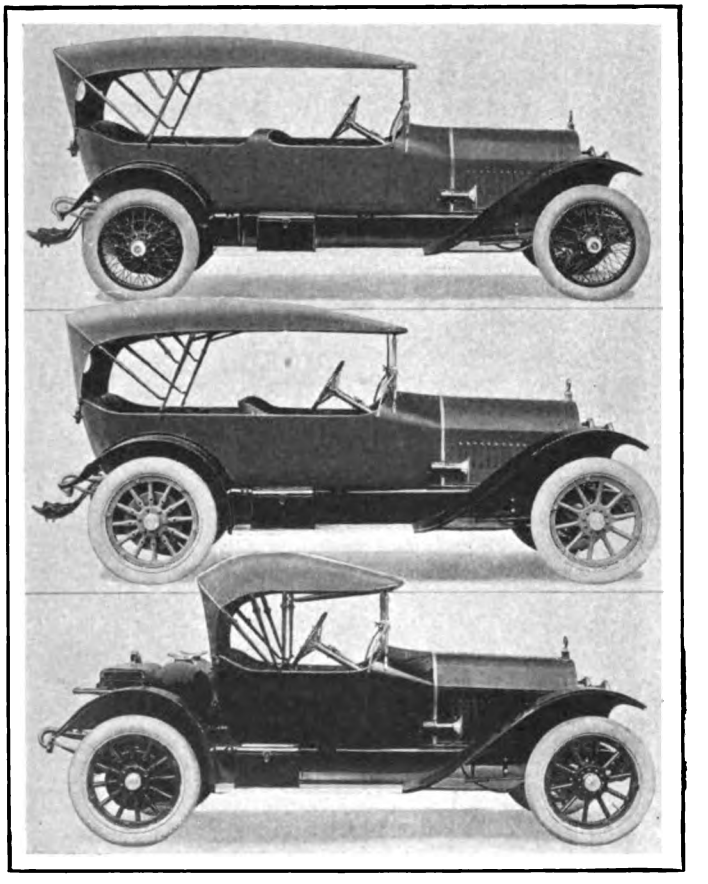
On the right side there is the carbureter feeding through a two-branch manifold to each cylinder block, and the magneto which is driven directly from the timing gears. The carbureter is mounted on a platform which is part of the aluminum crankcase. Also on this side but in the rear is a Remy cranking motor.

On the left is the Remy generator driven from an extension of the water pump shaft as illustrated, and the exhaust manifold which has a hot air attachment feeding through flexible tubing to the carbureter.

The Transmission System

The cone clutch, with springs beneath the leather to effect easy engagement, is continued unchanged. The pedal may be adjusted to suit the driver's requirements, the length of motion being 2½ in. Continuing in the drive, there is an inclosed propeller shaft, the torque tube surrounding it attaching to a face plate back of the clutch. A three-speed gearset is mounted on the rear axle the gearset bearings being balls. The rear axle, which is a semi-floating design has tapered-roller bearings on the inner ends of the shafts and ball bearings on the outer ends.

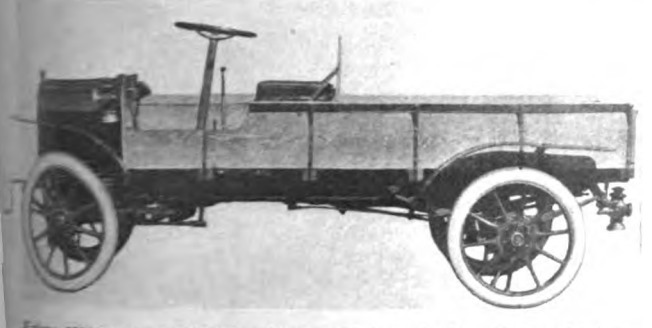
The Stutz company offers many color options for its bodies, these being, vermillion, Monitor gray, Mercedes red, yellow and white for the Bearcat; Red, blue, battleship gray and white are offered on the Bulldog; vermillion, gray, white and red on the roadster and red, blue, white and gray on the Bulldog special. Upholstery color options for the coming season are red, green and black.



Top—Stutz four-passenger Bulldog special which sells for $2,550. Middle—Bulldog model which lists at $2,250. Bottom—Roadster marketed for $2,100

Falcon Truck of 1000 Lb. Capacity

One of Detroit's most recent additions to the commercial vehicle field is the Falcon Motor Truck Co., which has been organized by A. B. Mallow of Detroit; F. B. Houston of South Charleston, Ohio, and A. B. Hazzard of Detroit. The Falcon will be a truck of 1000 lb. capacity with 1200 lb. capacity as a maximum. The price will be $750. A. B. Hazzard, well known as an efficiency engineer in the East and Middle West, is the designer, and the first vehicle has been under thorough road test for some time. The company has engaged factory quarters at 811 West Jefferson Avenue, Detroit. A. B. Hazzard, engineer of the Falcon company, was general manager of the Morton Poole Co. of Wilmington, Del., from 1906 to 1914, manufacturing high-grade machine tools. Previous to going to Wilmington he was one of the department engineers of the Rand Drill Co. of New York. The Falcon has a four-cylinder motor with 22 hp., cooled by the thermo-syphon system. The radiator is set in a pressed steel shell. Ignition is Atwater Kent and the clutch is a cone. The carbureter has a final set adjustment and is a Modern with a hot air connection. Lubrication is constant level maintained with positive action pump. This is connected with the dash where there is a sight feed. The selective sliding gearset is in unit with the motor and control is from the center. There are three speeds forward and reverse. The springs are semi-elliptic in front and full platform rear. Artillery pressed steel wheels are 30 in. with 3½-in. pneumatic tires. Steering is on the left and is very rigid and adjustable to wear. Wheelbase is 106 in. and tread is 56 in. The Falcon has a pressed steel frame of heavy channel section and the body is 40 in. in width and 9 ft. in length, with a single seat for the driver. The front axle is I-beam, forged and heat-treated. The Falcon has a capacity of 1000 to 1200 lb., and the price will be $750.



Falcon 1000 lb. truck fitted with express type body. This vehicle is sold by the Falcon company for $750

Why Two Brakes Are Necessary

EDITOR THE AUTOMOBILE:—In THE AUTOMOBILE I have noticed that M. P. B. of Beacon, N. Y., wants to know why two two sets of brakes are used on a car. If he would borrow his neighbor's car and drive it up an incline, apply the service brake till the car comes to a standstill, then release the brake and see how nicely the car starts to roll down the hill, he would know.

Like many others, M. P. B. seems to have the wrong idea of an emergency brake. A great many people think this brake should be used only in case a terrible accident were impending.

A young man in Dallas last week, driving for the third time, applied the so-called emergency on a short curve in Cliff Park so tightly that it took two men to release it. It turned the car completely over, killing him and his wife.

Dallas, Tex. D. C. E.

—There is no doubt but that in many respects the words "emergency brake" are a misnomer. The emergency brake is not primarily intended for short stops in dangerous situations, as the name would imply, but rather, as you suggest, to hold the car stationary on an incline. It is unfortunate that the name "emergency brake" ever became applied to the hand brake of an automobile because the very name has caused people to misuse it with disastrous results to themselves, as you suggest in your communication.

It must be remembered that to bring the car to a stop in a most efficient manner it is not necessary to lock the wheels; in fact, a car will stop quicker if the brakes hold the wheels just short of locking them than if they are locked. The reason for this is simple. When the wheels are locked the car becomes virtually a sled, sliding along the ground with nothing to stop it except the frictional resistance between the glazed tire and the road or any obstacle which it may hit. Once the wheels are locked the brakes are of no more effect. The motion of the car has passed beyond the control of the driver because neither the ordinary stopping mechanism nor the steering gear has any more effect. He is powerless to alter the direction or speed of the car, and when the brake is locked on, as it sometimes is, in a moment of panic where the hand brake is jerked back with the power lent by fear, the car is apt to turn across the road or into a ditch without any means of stopping it.

Unless the car is standing still the wheels should never be locked. Not only does it put the car out of control, but it acts in such a way on the tires that their life is considerably shortened. A driver who dashes along at 20 or 25 miles an hour toward the curb and then brings up his car short by jamming on his brakes, is not only a poor driver but is extravagant and uneconomical in the handling of his car. In the same manner the driver who approaches a sharp curve at a high rate of speed and does not stop until he suddenly throws on his brakes within a few feet of the danger spot, is courting disaster.

The so-called emergency brake has many uses and it could not be dispensed with, but at the same time it should not be misused. One of the places where a hand brake is a matter of almost necessity is in starting a car on an incline. Without the brake to hold the car in position it would be apt to roll backward, rendering it impossible to put the gears in mesh. It is also of use where the service brake becomes so worn as to be unreliable, but in these cases the hand brake should only be used long enough to enable the operator of the car to bring it to a place where he can have the service brake renewed.

Preventing Clutch from Grabbing

Editor THE AUTOMOBILE:—I have just bought a 1912 Herreshoff roadster. The clutch grabbed very viciously and on inspection I found that the previous owner had been running it dry. I filled the car with thin oil, but with the oil in I cannot throw the clutch out completely. I drew off the oil and thoroughly cleansed the clutch with kerosene. With the kerosene in the case the clutch works all right, but grabs very little. On putting back the oil again the clutch still pulls when thrown out. Would it matter if I ran the clutch dry or in kerosene? What would you advise?

Philadelphia, Pa. O. S. R.

—If the clutch works satisfactorily with kerosene as a lubricant it would be very good practice to keep the kerosene in the housing. Quite frequently a half-and-half mixture of kerosene and light cylinder oil is employed to hold the good qualities of a clutch. The half-and-half mixture would probably work very well in your case. If the clutch drags somewhat the pedal throw adjustment should be altered so that the clutch is removed further from engagement.

Setting Up Connecting-Rod Bearings

Editor THE AUTOMOBILE:—Will you kindly describe the best way to set up connecting-rod and main bearings for casing? If possible give illustrations thereof.

I refer mainly to such bearings that overlap the sides the bearing cap as is common in die-cast bearings.

Babylon, L. I. P. K

—The common method of procedure is to set up the connecting-rods in a fixture, which is fitted with a mandrel little smaller than the inside of the finished bearing. The fixture has a recess at the top and bottom, which allows metal to partially flow over the sides of the connecting-forming the flanges on the finished bearing.

The babbitt is poured through a hole in the top p Upon removing the connecting-rod from the fixture the bitt lining is found cast in place. A swedge is then fo through the bearing in order to make sure that the li is in perfect contact with the connecting-rod at the back. bearings are then scraped or reamed in the usual manne fitting bearings.

Suggestions regarding the manner of carrying out this work have been given by one of the large manufacturers of babbitt as follows:

1—Use an absolutely clean ladle and pot. When the metal is hot enough to brown a piece of paper or white pine stick, stir thoroughly and remove any skimmings caused by oxidation.

2—Be sure the faces of boxes and mandrels are clean and free from grease or dampness.

3—Pour rapidly into the box, holding the ladle as closely to the work as possible to avoid air bubbles, until it is half full; then pour gradually until filled, allowing large enough gate to take up shrinkage. When pouring castings with wide surface use ladle with wide lip.

4—To insure perfect boxes in pouring large bearings it is advisable to run chalk on mandrel or shaft and to have the mandrel hot. Mandrel and box should be about same temperature.

5—Do not keep babbitt metal at the melting point longer than absolutely necessary, as the chemical action of extreme heat tends to oxidize a composite alloy, causing deterioration, disintegration, addition to its brittleness, and materially affecting its anti-friction qualities.

6—When necessary to peen, it is best to commence up and down a center line, extending blows right and left of this line until tightened in place.

7—Finally, when you have a good metal, treat it as such and you will have no occasion to complain of the results obtained.

How to Splice Inner Tubes

Editor THE AUTOMOBILE:—I have several good inner tubes with some bad tears in them. What repairing outfit and what materials do I need for cutting out a section, say 6 in. long, and inserting a new section?

Batesburg, S. C. A. E.

—The large car concerns can supply you with a pair of mandrels for making this repair. The sections to be inserted may be either secured from old tubes of the same size, if any can be found which are in good condition, or when these cannot be secured the larger tire concerns can supply you with tubing of the proper diameter. The set of mandrels for splicing the tubes consists of a pair of these devices, one fitting within the other. They are shown at *A* and *B*, Fig. 1. One end of the tube is pulled through the mandrel at *A* and turned back over the edge about 4 in. The other side of the tube to be spliced on is pulled through the mandrel *B* and turned back over the edge about 8 in. It is then pulled back toward the other side a distance of about 4 in. The edges are then beveled and buffed, as shown in the illustration, and one heavy coat or two light coats of pure gum cement are applied. The cement is then allowed to dry thoroughly, a condition which can be determined by the tackiness of the cement to the touch.

Caution should be taken in joining the tubes that the inner tube is not twisted, but that the ends meet correctly so that when joined there will be no twist in the tubes. Acid curing solution is applied with a wide, soft brush to the part which has been cemented, and then the end of the tube on mandrel *A* is transferred to the end of the tube on mandrel *B*. The spliced ends are then immediately wrapped with strips of muslin or strips of inner tubing. From 15 to 20 min. is sufficient for the acid curing solution to form a perfect union. When the joint is unwrapped the tube is removed through the slots in the mandrels and the splice is complete.

It is stated that acid-cured splices will not loosen and are not affected by heat from the tire. On this account they have a distinct advantage over the old method of splicing with cement only, a process which is known as the cold method. If the splice does not cure together it is an indication that the work has not been done quickly enough after applying the acid solution, or that certain solvents in the acid solution have evaporated. To avoid this latter trouble the acid solution should be kept in a glass bottle, jug or earthenware vessel and tightly corked when not in use.

The Firestone company gives the following advice after making a repair on an inner tube: First, see that the washers on the valve are screwed down tightly at the base so that they don't leak. Two, see that the plungers or valve insides are not worn and that they are in good working condition. Three, inflate the tube, testing it in water to see that there are no small leaks which may have been overlooked during the work. Four, see that the proper length of valve is used with the tube. Short valves are used for regular clincher tires or quick detachable, and the long or extension valves when the tires are used on demountable rims such as are on the late cars.

Misalignment Causes Grind in Differential

Editor THE AUTOMOBILE:—How fast should a 1912 Buick model 36 roadster be able to travel?

2—Would oversized tires help to run it any faster?

3—What would cause a grind in the differential when the car is coasting? It is all right so long as it is pulling.

4—How fast should a 1914 Maxwell 25 travel when in good condition?

5—What would you recommend to increase the speed of the Buick car?

Hartford, Conn. L. H. S.

—This car should be able to travel 50 m.p.h.

2—Oversized tires would not help the car to go any faster; in fact, the tendency is to reduce the speed somewhat when oversized tires are used.

3—The only cause of a grinding noise in the differential would be first, a serious misalignment or maladjustment of the two gears, and second, a foreign substance in the gear-case. Any such noise as this is more apparent when the car is coasting ahead of the motor, as this allows the rear wheels to take up the back lash in the driving gears. This should be taken to a first-class garage where a mechanic can take up the play and put the gears in proper mesh.

4—These cars can probably travel 50 m.p.h., although the speed will depend so much upon the condition of the car and motor that it is not possible to say definitely.

5—The speed could probably be increased by advancing the timing and increasing the gear ratio between the motor and the rear wheels.

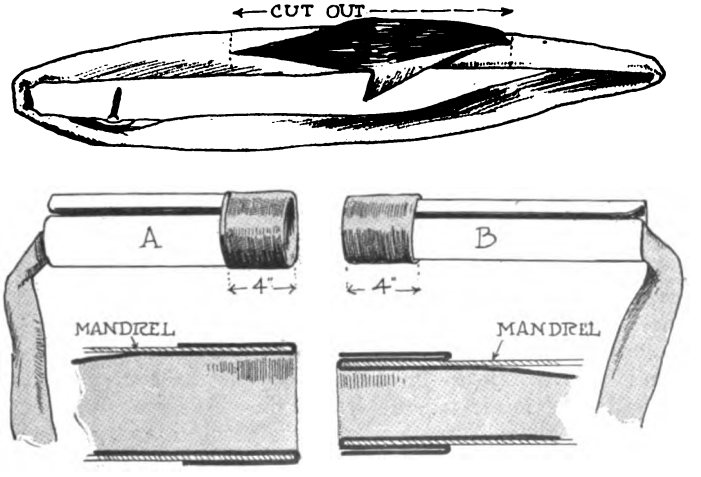


Fig. 1—Diagram illustrating method of splicing an inner tube with a mandrel. Mandrel A is pushed up close to the mandrel B and the turned over portion on A is turned over onto the doubly turned portion on B to make the splice

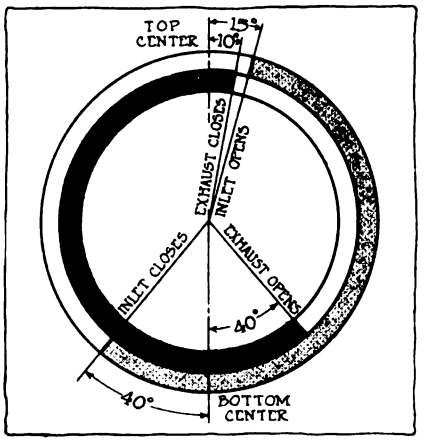

Fig. 2—Timing diagram in common use

Horsepower and Torque Curves of Moon 6-40

Editor THE AUTOMOBILE:—I note in the last issue of THE AUTOMOBILE in the Rostrum that a number of horsepower curves of different makes of motor are furnished together with the torque curves. I have a model 6-40 Moon car which has a 3½ by 5 motor and I would like to know the brake horsepower developed at different speeds, together with the torque.

New York City. J. E. S.

—The horsepower and torque of the Moon model 6-40 are shown in Fig. 3. These curves indicate the brake horsepower and torque at the different r.p.m. between 600 and 2000. It will be noted that the horsepower is just above 15 at 600 r.p.m and at 2000 it is above 47. The torque is at a maximum between 1000 and 1200 r.p.m. The torque is measured in pounds at a radius of 15 in. and to reduce this to foot pounds it is necessary to multiply by fifteen and divide by twelve.

The S. A. E. horsepower of this motor is 29.40 which, according to the curve is developed at about 1050 r.p.m. The point of maximum torque coincides with about the point of S. A. E. horsepower although the torque curve is quite flat between 1000 and 1200 r.p.m.

Has Difficulty in Changing Gear

Editor THE AUTOMOBILE:—I have a 1915 Oldsmobile, model 42, and have never been able to change gears from high back to intermediate without slowing down to 5 or 6 m.p.h. I have tried every way. By throwing the lever back in second very quickly at the same time the clutch is thrown out, also to hesitate a very short time in neutral, also to speed up the engine a little while in neutral, and none of these ways help.

My garage man says my clutch does not stop quick enough and has no adjustment on it. He can change gears backward better by not throwing out the clutch at all.

Tyler, Tex. O. M. B.

—The fact that the car has to be slowed down to such an amount before you can change gears shows that there must be some binding in the gearbox which immediately checks the speed of the gears to such an amount that you have to slow down in order that they revolve at the proper rate of speed to engage themselves. In view of this it would be well to examine the gearbox and see if the gears are properly lubricated, and especially if the layshaft is bound in any way which prevents it from rotating freely. It is evident that one gear is rotating so much more slowly than the gear which you desire to mesh with it that it is necessary to reduce your speed almost to a stop before you can engage the gears. This should not be the case on intermediate gear, although it very often happens on low gear where the reduction is so great that the relative car speed must be quite low. On intermediate speed you should be able to drop into gear at 20 m.p.h. without any appreciable clash. It may be that you can overcome the trouble to some extent by making your changes exceedingly quick, being careful to throw the gear over swiftly at the same time that the clutch pedal is depressed.

No Intake Charge Is Lost

Editor THE AUTOMOBILE:—I have noticed that the inlet valve of a motor remains open some 30 to 50 deg. past bottom center. I should think this would allow some of the charge taken in to be expelled. Why is this?

Pelham, N. Y. J. F. B.

—The reason for the intake valve remaining open beyond lower dead center is to take advantage of the inertia of the incoming gases which have been set in motion by the piston on its suction stroke. As the piston descends on the intake stroke with the intake valve open it tends to pull the gases in the intake manifold after it. This suction starts the intake gases in motion, with the result that they pour rapidly into the cylinder to fill the partial vacuum in the combustion space. When the piston reaches the bottom of its stroke these gases are still in motion, pouring into the cylinder, and contain a certain amount of energy which causes them to continue in that direction. In addition to this there still remains a partial vacuum in the cylinder which aids in maintaining the entrance of the gases.

It takes an appreciable time before the pressure in the cylinder reaches atmospheric pressure and before the inertia of the gases has dropped to such a point that they no longer tend to rush into the cylinder. For this reason in arranging the valve timing engineers leave the valves open for some distance past lower dead center. It must be remembered that, for a crank angle of 30 deg., the piston only travels on the upstroke about 5 per cent of the total distance. In other words, for a motor with 4-in. stroke, the upward travel of the piston for a crank angle of 30 deg. will only have been 0.2 in. For the angle of 50 deg. the travel of the piston on the upward stroke is about 14 per cent of the total travel, or in other words, in a motor of 4-in. stroke the travel at the extreme angle of 50 deg. would be just a little over ½ in. It can readily be seen that this small travel of the piston would not begin to drive the gases out of the valve on account of the inertia of the incoming charge and the partial vacuum still remaining.

This upward travel of the piston with the intake valve open undoubtedly represents a loss of volumetric efficiency in the motor, but there are no motors in existence which have perfect volumetric efficiency, and the 5 per cent loss with a 30 deg. angle of valve closure would not make any material difference.

Explanation of High-Mica Trouble

Editor THE AUTOMOBILE:—Would you be kind enough to explain through THE AUTOMOBILE the reason for the action of the Wagner motor generator and cut-out due to high mica as explained in your answer to H. Eulburg in the June issue?

I am not familiar with the machine or its means of regulation but, comparing your answer with the conditions, there are a few things which are not clear to me.

If the brush contact was so poor that the machine did not generate enough voltage to close the cut-out, closing it by hand would allow the battery current to excite the field, raising the armature voltage high enough to support it and charge the battery; but if the speed of the machine was lowered so its voltage dropped to zero, I do not see how the cut-out could close by itself even if the speed were again raised, for the conditions would be the same as when it was first started. Also I should think there would be bad flickering of the ammeter at low speed and a very noticeable falling off of the charging current at high speed, due to very poor brush contact caused by the action between the brushes and the mica. Please state regulation used.

Bronx, N. Y. A SUBSCRIBER

—Assuming that the brush contact was so poor that the machine did not generate enough voltage to close the cut-out, closing it by hand would allow the battery current to excite

the fields, raising the armature voltage high enough to support itself and then charge the battery. If the speed of the machine was lowered so that its voltage dropped so low that the relay opened itself, and then the machine was again speeded up, there would be a small amount of residual magnetism which would assist the dynamo to pick up and start generating again. The residual magnetism would not be sufficient if the machine had been shut down for any length of time, and, therefore, when first starting the engine, it might be necessary to close the relay by hand and allow the battery to excite the generator field in order to make the generator pick up. No external regulating devices are used in these outfits. All the regulation necessary is secured from the inherent regulation of the generator itself.

Trucks Used by U. S. Quartermasters

Editor THE AUTOMOBILE:—What are the different makes of automobile trucks used by the United States Army, Q. M. D.?

Fort Warren, Mass. W. S.

—The following tabulation shows a total of sixty-one motor trucks used by the U. S. Army Q. M. D., and is complete up to June 30, 1914:

MAKE	STATION	BY WHOM USED
Alco, 1912	West Point	Quartermaster Corps.
Alco, 1912	West Point	Quartermaster Corps.
White, 1911	West Point	Quartermaster Corps.
[illegible], 1913	Galveston	Quartermaster Corps.

Probably Carbureter Needs Adjustment

[illegible] THE AUTOMOBILE:—Can you tell me what is the [illegible] with my Cutting 1913 model B-40? The car runs well and has just been overhauled, but I can only get 20 miles and then it will start to spit and miss and lose speed and I will have to take it easy for another half-mile, and then it will run all right again until I reach the 25-mile mark again. I have had a Stewart system put on but it does not do any good. The gasoline is good and clean.

Is the carbureter on this car large enough? The motor is a 4 by 5, Wisconsin. What is the speed of this car and the S. A. E. horsepower?

Carver, Minn. C. E. D.

—The carbureter should be a 1¼-in. size, or, in other words, if it is a Rayfield design, as is standard equipment on this make of car, it should measure 1½ in. across the manifold connection. With this size carbureter and with the motor in good condition it is only a matter of adjustment to get the motor operating properly.

The S. A. E. horsepower of this car is 25.6, and it should be able to travel up to 60 m.p.h. with everything in first-class condition.

Wants Parts for Halladay Car

Editor THE AUTOMOBILE:—Where and of whom can I get clutch repairs, also steering device repairs, gears, etc., for a Halladay touring car? It was made in about 1908 or 1909, and has a Rutenber motor.

Buhler, Kan. L. P. B.

—Repairs for the Halladay touring car can be secured from A. C. Barley, Trustee of the Streator Motor Car Co., Streator, Ill.

Interested in Gasoline Substitutes

Editor THE AUTOMOBILE:—I would appreciate if you would send me the names of people or companies who manufacture a fuel that takes the place of gasoline.

Some time ago I read about a party in THE AUTOMOBILE who was trying out some fuel at the Indianapolis Speedway.

Henderson, N. C. G. E. B.

—The fuel you refer to is undoubtedly Zoline, which was experimented with by a number of engineers at the Indianapolis track. It was found that the fuel was not practicable and it is no longer in existence.

No Motor Interchangeable with Ford

Editor THE AUTOMOBILE:—Can you give me the name of some manufacturing concern which could build a motor for a Ford that will speed up to 3000 r.p.m.?

Pilot Rock, Ore. E. R. R.

—We do not know of any concern making a motor which is interchangeable with that of the Ford. If you were to have a special one made by some concern, it would cost such an amount of money, that it would be quite an outlay.

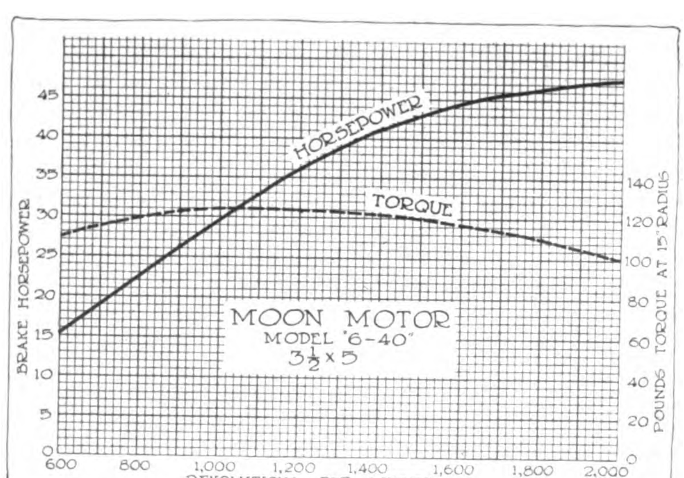

Fig. 3—Horsepower and torque curves of the Moon model 6-40 showing pounds torque at a 15-in. radius

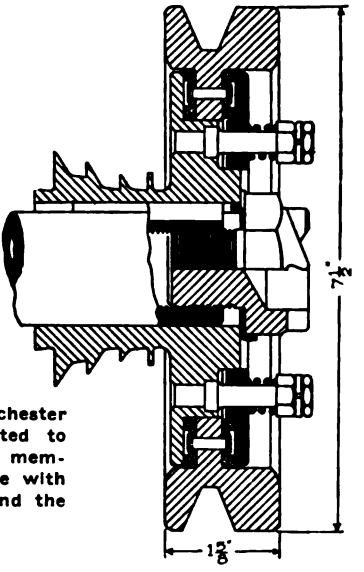
Packard Uses Vibration Damper

American Patent Rights for Lanchester Invention Acquired—Device To Be Used on Twin Six



Section of Packard-Lanchester vibration damper as fitted to the twin six. The inner member is made in one piece with the oil throwing rings and the starting crank jaw

DETROIT, MICH., Aug. 2—The Packard Motor Car Co. has purchased the American patent rights for the Lanchester vibration damper, buying outright patent No. 1,085,443, granted to F. W. Lanchester Jan. 27, 1914, the Packard company also holding two other patents of a somewhat similar character obtained by Haydon, these being Nos. 795,698 and 800,572.

To Grant Licenses

It is the intention of the Packard company to grant licenses to other manufacturers who may desire to use the damper, and it is understood that the royalty asked would not be very large. As can be seen from the drawing, the damper is small and is quite cheap to manufacture. In the Packard case the loose rim is employed to drive the fan belt and there is only one inner member of the clutch instead of the several used in the original devise. Also dry surfaces of asbestos fabric are used instead of lubricated steel plates.

How the Damper Works

With a six-cylinder crankshaft, whether there be six pistons or twelve, one of the commonest forms of vibration is that produced by the twisting of the shaft at certain speeds. The shaft has a natural period of vibration if deflected torsionally, and when the sequence of explosions coincides with the natural vibration period the pendulum effect causes the violence of the vibration to be increased. The matter was explained fully in THE AUTOMOBILE for Feb. 18, 1915; the vibration which is perceptible to the passengers in the car is due to the front crank throw twisting with each explosion, and then the spring of the crank jerking the piston back as soon as the power stroke is over. Elasticity of the steel causes oscillations to take place, so the crank flies back too far, springs forward again and so vibrates many times before returning to its proper position, by which time the succeeding explosion again displaces it.

Resists Return Spring of Crank

The oscillation of the piston disturbs the center of gravity of the whole piston mass much more than the first deflection does, and the object of the Lanchester damper is to resist the return spring of the crank so that the twist caused by the explosion is made "dead beat."

Lanchester's Original Design

The original design of F. W. Lanchester, a leading British automobile engineer, was to mount on the front end of the crankshaft a little flywheel and disk clutch. The inner member of the clutch was secured to the shaft and the flywheel rim rode loose. Thus when the crank twisted forward the inertia of the flywheel rim caused it to try to maintain a steady speed and the clutch slipped a little, and when the crank tried to twist back at the end of the power stroke the flywheel rim again resisted the tendency to oscillate. The sum total of effect is that the energy of the twisting crank is absorbed by friction between the clutch surfaces and the rapid oscillations are prevented. Something depends upon the strength of the clutch spring in the damper, as the little flywheel rim must be sufficiently loose to be able to act as described, but not so loose that the friction will be too small to absorb the energy of torsion. The adjustment is not delicate and once the proper strength for the clutch spring has been found the damper can be made on a production basis and fitted complete without any further attention.

When first tried out the effect of the damper was amazing, turning a six-cylinder motor with a weak crankshaft and two bad vibration periods into a smooth and almost vibrationless engine. Broadly, it may be said that a 2-in. crankshaft with the damper is the equivalent of a 2½-in. shaft without the device.

Packard Tries It Out

In developing the twin six the Packard Motor Car Co. tried a 2.125-in. crankshaft and found that there was a periodic vibration at a certain speed that could just be detected by an experienced engineer who watched for it, though the ordinary man would never have discovered it. It was not sufficient in force or in duration to warrant the use of a larger crank, so an experimental Lanchester damper was made up and fitted to an experimental chassis. The effect was entirely to remove the "period" and also it seemed to make the engine smoother than ever throughout the whole wide range of its speed. Accordingly the Packard company purchased the American rights of the invention.

Nine Possible S. A. E. Candidates for National Advisory Board

NEW YORK CITY, July 31—The members of the council of the Society of Automobile Engineers met to-day at the headquarters of the society for the purpose of selecting the two members of the society to serve upon the advisory board for national defense which is operating with Secretary of the Navy Daniels and will be headed by Thomas A. Edison. Although it was first thought that the council would directly appoint the members of this committee after a meeting lasting from 10 o'clock this morning until after 4 this afternoon, without recess, it has been decided to present the names of the candidates to the voting members of the society for a secret mail vote. There are nine of these candidates and they have been written for their consent, after which their names will be inscribed upon the ballots and forwarded to the voting membership. It has been aimed to expedite the selection, and to this end the prospective nominees have been asked to wire their acceptance. Immediately upon receipt of this the ballots will be sent out.

Analysis and Valuation of Motor Fuels —14 Methods of Examining Them

FROM GERMAN DATA

(Continued from last week)

ONE of the effects of mixing volatile and less volatile components may be noticed in the case of the mixture of 50 per cent gasoline and 50 per cent benzol. By figuring from the evaporation time for 100 per cent benzol, 2 hours 23 minutes, and that of pure gasoline, 57 minutes, the evaporation time for the 10 cubic centimeters of the mixture should be 1 hour 40 minutes, but the actual time, as given in the list, is 1 hour 56 minutes. The evaporation is not uniform, but the lighter component evaporates rapidly carrying with it a portion of the heavier component, and thereafter the remaining heavier portion evaporates slowly. For this reason mixtures of very light and heavy components are not good motor fuels despite their relatively low specific gravity. [Compare for figures test No. 12.]

The following observation throws more light upon this rule. A light gasoline of .660 specific gravity and boiling point limits 45 and 80 degrees C., showed an evaporation period of 30 minutes, and a heavy gasoline of .750 specific gravity and boiling points 120 and 130 degrees showed a period of 7 hours. When these are mixed, producing a fluid of .700 specific gravity, every motorist will from this indication take the mixture to be a first-class gasoline. But its evaporation period is more than 5 hours, while the mean of the periods of its components would make only 3 hours 45 minutes. As gasoline of this order causes the motor to skip and leaves some of its least volatile portions in the carburetor [compare provisions made in some modern carburetors to drain off all liquid surplus or lead it to the point of strongest suction], the time test for evaporation gives a valuable clue to the dependability of the fuel for motor purposes. [The test might be expedited by having a definitely determined cold draft pass over the fluid or pumped against it from above, but not by raising the temperature of the air. —Ed.]

5. Behavior Toward Litmus

Gasoline or benzol can be tried for acidity with litmus paper. In the case of gasoline, it may also be shaken up with tincture of litmus. Even after standing for some time no change in the coloration of the litmus should take place. Most gasolines are found to be neutral, but a few of the heavy gasolines show a faint acid reaction. The benzols show usually a trace of alkaline reaction, but this may be due to a removal of pigment cells by solution, causing a faint bluish tint. Motor alcohol reacts with weak alkaline effect due to the pyridine used for denaturing it.

6. Color Reactions with Sulphuric Acid

A high-class cylinder with a ground stopper is first rinsed with sulphuric acid to remove all impurities, is then partly filled with the acid, whereafter the motor fuel is poured in and shaken up with the acid. When the two fluids have separated, the colors and actions of both are observed with a sheet of white paper for background. Where gasoline is brought according to specifications it is usually demanded of a high-class light gasoline that no change in coloration shall take place, while a yellowish coloring of the acid is permissible with heavy gasolines. The tables [of 92 fluids in the German market; here omitted] show that even the best gasolines nearly always color the acid with a faint yellowish tint and that the heavy gasolines color it yellow to yellowish-brown. The demands should probably not be made more severe.

How it comes that some of the best gasolines lose in clearness by the test with sulphuric acid it has not been found possible to explain decisively.

For "90 per cent" benzols yellow coloration of the acid must also be accepted as admissible.

In the case of motor alcohol a marked rise of temperature with change of volume occurs at once through formation of ethyl ether, and any admixture of alcohol produces the same indications in lesser degree.

7. Benzol Test with Isatine-Sulphuric Acid

The sulphuric acid test just referred to shows in general if there are impurities due to unsaturated combinations of the order C_nH_{2n} and aromatic hydrocarbons. Quantitatively such impurities are shown, by Kraemer's and Boettcher's method, by weighing the amount absorbed in a mixture of 80 volumen per cent concentrated sulphuric acid and 20 volumen per cent fuming sulphuric acid. This process is applicable within the limits of 10 to 12 per cent of the impurities mentioned, but for larger percentages it is found [by Dr. Dieterich] that the sulphuric acid does not suffice for producing a quantitative transformation into sulphurous acids, and, as the amount of admixtures is not known in advance, the test can be only conditionally decisive.

Test 6 can be supplemented by adding isatine (.1 gram isatine to 30 grams sulphuric acid) to the mixture of gasoline and sulphuric acid, shaking the new mixture carefully and, after a short rest, observing the coloration. This done, the mixture is left standing 1 to 2 hours and the final coloration is then observed.

The object is to show the possible presence of thiophene which is a sulphurous impurity of benzol and with the isatine produces a pretty greenish-blue to midnight-blue coloration. But the test shows only thiophene with certainty and the benzol merely by an inference which is not quite safe, while benzol, on the other hand, is not shown if it is free from thiophene. It is due to this imperfection of the test that gasolines with strong benzol admixtures do not show the characteristic greenish-blue coloration but only greenish-violet or brownish shades. If the test is employed it is important to leave the isatine mixture standing for some length of time, as the true isatine coloring does not develop at once.

In practice the test can only be recommended when the purpose is to examine benzol for sulphurous impurities, especially thiophene.

8. Benzol Test by Nitration with Nitro-Sulphuric Acid

To isolate the nitro-combinations of benzol, the toluols and xylols, which constitute the aromatic hydrocarbon impurities of gasoline, the following process is employed.

Ten grains of the gasoline to be examined is mixed in a large retort with ten times as much of ice-cooled mixture of one part sulphuric acid and two parts crude nitric acid, and

the odor which is shortly noticed, if aromatic combinations are present, is tried for nitrobenzol, nitrotoluol, etc. With frequent stirring the mixture is left cold for one to two hours; thereafter it is heated slowly for several hours in a steam or hot-water bath and finally the retort is heated more strongly in an oblique position until the brownish-red vapors disappear and the mixture assumes a light yellow color. It is then allowed to cool, the odor is again examined and the mixture is diluted with an amount of water 10 to 15 times as large. When this has come to rest, it is observed whether larger or smaller amounts of light yellow or orange oily liquid or crystals are segregated. If a very violent reaction arises at the beginning of the mixing, with immediate boiling of the fluid, the presence of a readily nitratable substance, such as denatured alcohol, is indicated.

If the test fluid is free from aromatic hydrocarbons, no odor and no coloring occurs; neither does of course any isolation of a nitro-compound take place. Nitrobenzol shows the well known oily consistency and intense odor of bitter almond oil. If nitrotoluol is present, the nitration product (also the watery liquid) shows after a few minutes a brown coloring when treated cold with melted sodium hydroxide. If the nitration product is nitrotoluol only, it takes crystalline form, while preponderance of xylol is shown by dark yellow coloring.

By nitrating once in the manner described, the benzol is mainly turned into nitrobenzol, $C_6H_5NO_2$, and the toluol forms, aside from small quantities of the meta [isomeric] combination, both the ortho and the para modification. Of these only the latter is crystalline, in long light yellow needles. The nitrotoluol, $C_6H_4CH_3NO_2$, does not smell of bitter almonds but has a special nitrous odor. Nitroxylol has a similar odor and is an oily liquid resembling in color the yelk of an egg. By the cold treatment with sodium hydroxide the nitrotoluol gives, as mentioned, a brown coloring, but this becomes blood red if nitroxylol is present in considerable quantity, especially by heating. Nitrobenzol remains perfectly unaffected by this test.

A quantitative determination of the nitrated products by means of ether has been repeatedly proposed, but is uncertain by reason of the high volatility of the ether and dangerous on account of the poisonous vapors. Giving products varying in quantity and composition it has not been found useful.

Very little information is found in technical literature with regard to the amount of aromatic hydrocarbons contained in the commercial gasolines. The chemical testing bureau of the city of Dresden notes, however, that three samples each showed 10 per cent of benzol. The present series of examinations has shown that even the best gasolines of Class A can contain small percentages of benzol and that those of class B almost without exception contain aromatic ingredients, while the heavy gasolines may not show benzol but always toluol and xylol and usually some unsaturated (olefine, C_nH_{2n}) combinations. When a large number of gasolines are tested at the same time, the colors and segregations alone indicate plainly enough the motor fuel values of the different fluids.

The fact that most of the motor gasolines in the market now contain aromatic hydrocarbons shows that the raw materials, the petroleums from which they are distilled, have undergone a change. To ask that a motor gasoline shall be quite free from benzol is therefore to go too far. A small and natural percentage of the aromatic hydrocarbons does no more harm in gasolines than in benzol, and is unobjectionable if the price is in accordance with the amount of these irregular components which to some degree indicate how far refinement has been carried in the manufacture of the fuel. [The indication is uncertain unless the composition of the raw petroleum used in the production is known.]

What quota of aromatic hydrocarbons should be allowed in each of the three classes of gasoline is a question referred to under No. 9.

9. Test with "Dracorubin" Paper

For distinguishing gasoline and benzol the use of iodine is well known. Dissolved in gasoline it becomes raspberry red, in benzol violet and in alcohol (making tincture of iodine) brown. But it is not suited to show an admixture of benzol in gasoline, as the colorations become too indefinite.

HOLDE'S test depends on the use of a specially treated asphaltum which affects gasoline very little but is solved in benzol with dark coloration. It shows benzol in gasoline, but the production of the asphaltum directly from petroleum and the leaching of it in different fractions of the gasoline are rather complicated processes. A more suitable substance has been found [by Dr. Dieterich] in the gum of the dragontree of Sumatra. The sap of this tree, as obtained by incisions, is called dragonblood and is a resin containing a red gum which is isolated by hot treatment of the resin with petroleum ether. The pure gum is thereafter insoluble in petroleum ether and in the form of a red powder which has been shown to be an ester of benzoic acid [a *Dracoresinotannolester*, Dr. Dieterich terms it]. This pure gum yields somewhat to hot gasoline but leaves only traces in cold gasoline, while in alcohol and benzol it is at once dissolved with magnificent blood red coloration. To produce this gum of dragonblood so pure that it gives up nothing whatever to cold gasoline of any of the three classes but immediately reacts to traces of benzol, 10 kilograms of dragonblood (of the best grade which comes packed in bast) was dissolved in 25 kilograms of petroleum ether, the residuum was again lixiviated in 15 kilograms of ether and from this solution the dragonblood-alban ($C_{16}H_{16}O$) was precipitated with 25 kilograms of absolute alcohol. The filtrate, after being steamed off, was boiled in 30 kilograms of petroleum ether and successively in hot petroleum, hot benzine and, finally, hot light gasoline. Some of the gum goes into the solvents, but after the last boiling the gum remains unaffected and insoluble in gasoline. The red gum powder obtained in this manner is what is termed "*Dracorubin.*" It is eminently adapted for demonstrating the presence of benzol in gasoline, and *vice versa*, and also for determining the values of different gasolines, benzols and motor alcohols.

This product has been placed in the market in the form of a reaction paper which is made by solving 2 kilograms of dracorubin in 8 kilograms of benzol and soaking filter paper twice in the solution. When dried the dracorubin paper is dark red and waxy in appearance. It is sold in packages containing 80 strips each at the Helfenberg Chemical Works Co. (at Helfenberg, Saxony, Germany). It is employed as follows:

Four strips of the paper are placed in a high clear and uncolored glass cylinder with stopper and the motor fuel is poured in till the papers are immersed. This is left standing, well stoppered, in ordinary indoor temperature till the next day. After shaking the cylinder, one removes the papers, and places a sheet of white paper under and behind the cylinder. For comparison a second cylinder is filled with ordinary gasoline. Two observations are now made, one relating to the color of the fluid and the other to the color of the four strips of paper after they have been dried. [Dr. Dieterich gives here a table showing the reactions with 33 fluids of interest in the chemistry of motor fuels, their impurities and adulterations. With regard to the sensitiveness and general usefulness of the paper, it is noted, for example, that the reactions for American, French and German turpentine are markedly different, indicating that this new testing preparation might be found of use in the paint industry as well as for detecting variations in the quality of motor fuels.]

In general, the results of tests of motor fuels with dracorubin paper are indicated in the following table:

REACTIONS OF DRACORUBIN PAPER

Color of Fluid	Color of Paper	Nature of the Fuel
No color at most faint rose pink green.	The dark red paper unchanged, when dried.	Class A gasoline, free from benzol and aromatic hydrocarbons; at most traces of these.
Dark to light [illegible]	Red.	Gasolines of class B or C or mixtures of gasoline and benzol or Class A gasoline with admixture of class C gasoline, containing benzol.
[illegible] with yellow- [illegible]	Lighter red than before used.	Class C gasoline with little benzol, but much toluol; high specific gravity.
[illegible] to dark [illegible]	Red to light red, finely mottled.	Mixtures of gasoline and benzol or gasoline with strong natural benzol content.
[illegible] red.	Pale mat tile, finely mottled.	Good "90 per cent" benzol.
Dark brownish [illegible]	Dark splotches on tile red.	Heavy benzol with toluol and xylol or heavy gasoline with toluol, but little benzol.
[illegible] red.	Light rose pink.	Denatured 95% motor alcohol.
[illegible] red.	Rose pink.	Denatured 90% alcohol.

To use the dracorubin test for an approximately quantitative determination of benzol in gasoline, the best method is to add 10, 20, 30, 40 per cent or more of benzol to normal gasoline ["normal" gasoline can be obtained in Germany issued by the Royal Bureau for the Testing of Materials at Berlin Lichterfelde and corresponding to close specifications, such as: Specific gravity .695 to .705, boiling limits 65 and 85 degrees C., free from benzol, does not color sulphuric acid], place dracorubin paper in these samples, and compare the different shades obtained with the color of the fuel under examination. Air and light gradually affect the colorations, however, and the sample solutions should therefore be renewed from time to time.

From the many dracorubin tests made it has become evident that nowadays even the finest gasolines contain small percentages of benzol, and it can be inferred from this fact that more petroleums containing benzol are being refined now than formerly; also that refinement of the gasolines is in part less thorough than in the earlier years of the automobile movement.

10. Nitrate of Silver Test

Adulteration of gasoline with volatile components of coal tar oils or lignite tar oils, which always contain sulphurous substances, is detected by the nitrate of silver test. Five cubic centimeters of the gasoline is mixed with one-fourth of this volume of alcoholic solution of ammonia and a few drops of nitrate of silver solution. Placed in a long test tube, this is dipped a few times in hot water and it is observed whether a brownish coloration occurs or not. With gasoline of class A there should be no such reaction, with those of class B a light coloration is admissible and with class C a light blackening. Benzols all show blackening, as they naturally contain sulphur combinations.

11. Calcium Carbide Test for Water

Any considerable quantity of water in gasoline or benzol appears in drops which can be seen without difficulty at the bottom of perfectly clear glass bottles and still easier in colored bottles. While neither of the fluids is miscible with water, both can absorb a certain amount of moisture, especially benzol. (Bright iron parts rust more readily in benzol than in gasoline.) To distribute whatever water may be contained in the fluid under test and thereby make sure of getting it in contact with the carbide, the fluid is first carefully shaken. A couple of pieces of perfectly dry calcium carbide are then added, and one observes by the odor if only air bubbles are the result or a strong development of acetylene occurs.

Motor alcohol of the 95 per cent grade gives scarcely any acetylene, while cooking-alcohol of 90 per cent gives a very strong development.

12. Fractional Distillation

While for commercial distillation it is important to determine the whole curve of boiling points of a fluid, the matter of most direct interest for judging motor fuels is to ascertain how much of the fluid in each case evaporates below 100 degrees C. and how much requires a higher temperature. To make sure of the figures on this point some departures from the usual methods were made in this series of examinations. The quantity of the test material was made larger, 250 grams being used in each case, and volume measurements were discarded in favor of weights. To get exactly the percentages passing over below 100 degrees C., the following method was followed.

In a calibrated fractional distillation retort holding 500 grams and made of Jena utensil glass (*Jenaer Gerätglas*) 250 grams of the motor fuel was weighed in, glass beads and a couple of glass capillaries being added to promote boiling, and was heated on the wire net over a small flame. The retort was also protected by wire caging at the sides and above, for security in case of breakage and fire. Without considering the momentary barometric pressure, the lower boiling point was taken as that thermometrical degree at which the first drop of distillate trickled from the lower end of the condenser to the receiver. The distillation was continued till the thermometer showed 85 to 90 degrees C. Then the retort was imbedded as deeply as possible—up to the point where the distillation tube branches off—in a chloride of calcium water bath arranged to have a boiling point of 110 degrees C., and with this bath held exactly at 100 degrees the distillation was continued so long as anything passed over. (About 66 to 67 per cent of crystalline $CaCl_2 + H_2O$, or else 34 per cent of melted $CaCl_2$ in a solution of 1.3124 specific gravity makes the required bath.)

By switching the chloride of calcium bath into the process it is possible to hold the temperature more exactly constant at 100 degrees than with the customary continuous distillation, and certain errors are thereby avoided, especially in the case of the heavy gasolines.

After cooling of the retort the weights were determined and thereafter the process was continued with direct flame above 100 degrees until the retort was empty or only filled with vapor. At this moment the second boiling point was noted. Each of the two fractions was kept and served subsequently for the optical test, No. 13.

Barometer readings were recorded for each test but no allowances for the variations were figured.

The usual conception of gasoline comprises those components of petroleum which boil below 150 degrees C. But it is seen from the detail tables [here omitted] that the actual motor gasolines of the present day go far beyond this limit. And as petroleum ether, with boiling points 28 and 40 degrees, does not come into the question for motor fuel purposes (being applicable only as an admixture to benzols, to increase the velocity of flame propagation), the motor gasolines can now be taken as including the distillation products from about 45 to 160 or 170 degrees C. Contemporary technical literature [HEFTER, HOLDE and UBBELOHDE are the authors mentioned] gives the boiling limits for first-class gasoline as 80 and 110 or 120 degrees, but it is apparent from the present series of analyses that motor gasolines must have wider limits in order to be recommendable. The best class A gasolines show boiling limits of about 45 and 110 degrees, and in accordance herewith it is especially the lower limit which must be drawn back to 40 degrees. A gasoline

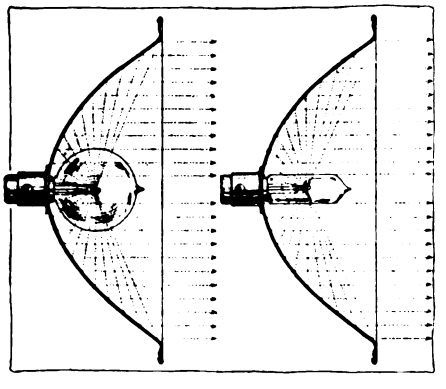
ACCESSORIES

Perfection Car Heater

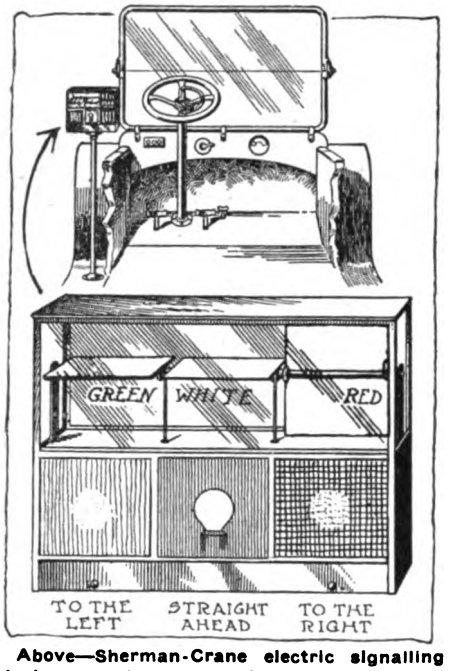
THE Perfection heater which radiates exhaust heat utilizes energy which otherwise is wasted and operates entirely without maintenance cost. A small valve on the exhaust pipe deflects about one-eighth of the hot burnt gases through a flexible steel hose to the heater where it warms the air in the car which circulates around the hot copper tubes of the heater. The heater is made in two types, one for passenger car use and the other for commercial vehicles. The passenger car type consists of a series of seamless copper tubes assembled into a manifold at each end, these radiating parts being carried in a rust-proof under-casing. The 9¼ by 13½ in. top plate which is mounted flush with the car floor is buffed and polished. The heater is 2½ in. deep and provides over 200 sq. in. of radiating space. A small lever projecting through the floor plate provides regulation of the amount of heat taken from the exhaust pipe. The second type of heater occupies only 3¼ by 15⅞ in. of floor space and is constructed in the same way as a passenger car heater except that the heat control lever is made as a separate unit and can be located wherever desired.—Perfection Spring Service Co., Cleveland, Ohio.

Electric Direction Signal

An electric signaling device to indicate the direction an automobile is going at street intersections has a double-deck arrangement, with flag and lantern effect, and is attached on the left side of the car near the edge of the windshield in such a manner that it can be seen easily from both front and rear. Green, white and red squares of glass are thrown to an upright position in the upper portion for the respective signals desired, and



How the Argon headlight bulb obviates obstruction of the reflected rays



Above—Sherman-Crane electric signalling device mounted on running board of a car. Below—Section through the device

lights of the same color are flashed in the lower part, thus making the invention suitable for use in both daylight and darkness. It is also equipped for having the horn sounded whenever the button is pressed for any signal. It is made of a metal frame, with glass sides, and is attached to the running board by a piece of ¾-in. iron pipe and flanges.

Green, the left or outside color, means a turn to the left; white, the middle color, means straight ahead; red, the color next to the car, means a turn to the right; while a combination of either side color with the middle color means a turn around in the direction of the respective green or red of the combination, all three are flashed together for stopping and the red and green are shown together for backing up. Signals are visible from any direction. The device sells for $15.—Sherman-Crane Automobile & Signal Co., Denver, Col.

Argon Headlight Bulbs

A new type of headlight bulb is the Argon which is filled with nitrogen gas, put into it by pressure. This gas contains a small percentage of argon, about 2 per cent, which, the maker claims permits the use of a higher voltage for a given filament. The filament is of drawn tungsten wire and is so coiled that when properly focused the lamp does not produce dark rings.

The bulb, which is elongated, will pass through the opening in practically any reflector and the bulb can be put in place from the back. Obstruction of the reflected rays from the part of the reflector nearest the center is obviated by the form of the bulb.

Another Argon type has a double filament, the main filament being for full lighting and the supplementary filament, which is placed back in the base so that it does not cast any rays on the reflector. This is especially adaptable for city use.

The candlepowers of the regular type Argon tubular bulbs are from 16 to 24 and the voltages are 6, 7, 8, 9, 12 and 18. Price, $1 each.—Wood Mfg. Co., Fairfield, Conn.

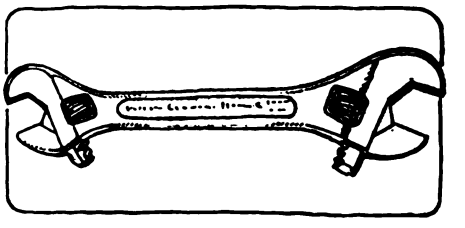
Noncarbene Fuel Improver

Noncarbene is a preparation designed to remove carbon from the cylinders and to keep this part of the engine always in efficient condition by its lubricating and cleansing action when mixed with the gasoline in the fuel tank. It is also claimed to increase the power of the motor and to effect a considerable economy by increasing the mileage per gallon of fuel. Noncarbene comes as a liquid in cans, together with complete directions for mixing with gasoline and a small metal cup measure for insuring the proper proportion, which is a ratio of ½ pint to 4 gal. of gasoline. It sells for 50 cents a quart, $1.50 a gal., $6.25 for 5 gal., $12 for 10 gal. and $50 for 50-gal. barrel. There is also a Tourist Package of sixteen half-pint cans for $2.—The Noncarbene Co., New York City.

Automobile Wiring Harness

A wire harness for the purpose of protecting the electric circuits from oil, water, grease, dirt, etc. which are apt to cause power leaks and short circuits has recently been brought out by the Breeze company. The wires are housed in the Breeze flexible metal wiring cover which acts as the armoring agent. This harness comes in a complete outfit containing sufficient material to cover all the wires to lamps, generators, batteries, starter, spark plugs, magnetos, dash equipment, etc., and the wires from different directions which come together in two-to-one and three-to-one joints at a common center can be readily drawn through the conduit.

Any number or lengths of wire can be used. The armor for the rear lamp is



Crescent wrench with 22½ deg. adjustable head at each end

black enamel for 3 feet, that for the front lamps is nickel-plated brass for 6 feet. The average total length needed for the largest cars is about 30 feet, but the outfit as put up comprises 45 feet of the covering, four two-to-one joints, two three-to-one joints, 20 feet of 5-16-inch inside diameter flexible wiring covering, 10 feet of 7-16-inch; 8 feet of 5-8-inch and 7 feet of 1-inch. The price of the outfit is $6.—Breeze Carbureter Co., Newark, N. J.

Double-End Adjustable Wrench

A double-ended and adjustable wrench, modeled after the solid engineer's wrench, is the latest Crescent model. A single-ended adjustable wrench is also produced. The adjustment is obtained by means of a screw and rack bar.

Two sizes are made: one has heads for 15/16 and 1⅛ nuts and the other ¾ and 15/16 nuts. The double ended pattern weighs but an ounce more than the single end tool of the larger size. Price, small size, polished, $1.25 each, $15 per dozen; nickeled, $1.60 each, $19.20 per dozen. Large size, polished, $1.50 each, $18 per dozen; nickeled, $1.90 each, $22.80 per dozen.—Crescent Tool Co., Jamestown, N. Y.

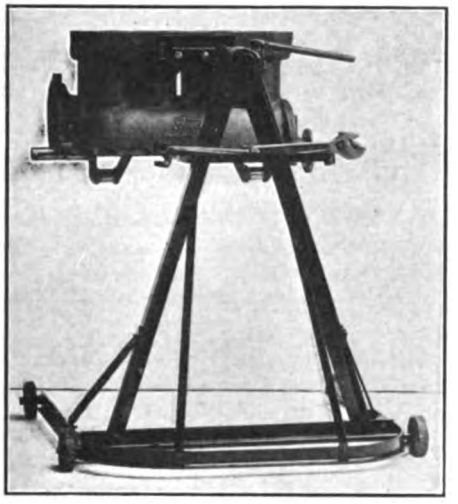
Ekern's Ford Products

A special stand for Ford motors is of great assistance in repair shops. The Ekern stand carries the motor attached to the stand by two bolts which screw into the sides where the water connections are bolted on when the motor is mounted in the car. The clamp and motor can be rotated together to any position and secured there by means of a split clamp. The stand is provided with small wheels which render it easy to move it around the shop. A tray on the stand holds tools and small parts which may be taken off the motor. The stand is 34 in. in height and takes up floor space 32 by 30 in. It weighs 50 lb. and sells for $20.

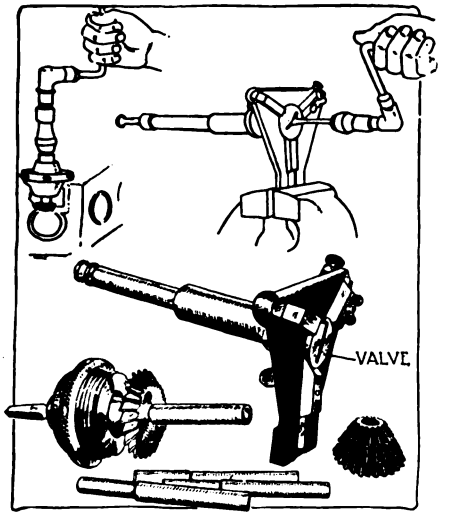
Another Ekern product is an attachment which renders it possible to tow in a Ford car with a broken axle drive shaft on its own four wheels. A frame carrying a stub axle is hooked on the housing flange at the bottom and held in place by tightening a set-screw at the top. The broken end of the shaft is removed from the wheel hub and the wheel slipped on the stub of the attachment. The car can then be towed in as well as if the axle were intact. The attachment weighs 6 lb. and sells for $5.—Ekern Bros., Flandreau, S. D.

Healy Valve Tools

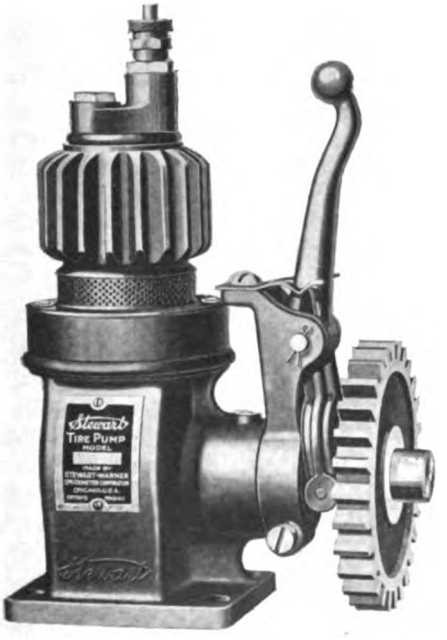
For refacing valves and valve seats a complete set of tools is put out by the Healy organization. The valve tool consists of a frame plate carrying three adjustable cutters with a guide extension to take the valve stem and hold it steady.



Ekern stand which permits mounting of Ford motor in any position



Healy set of tools for refacing valves and valve seats of any size



Stewart single-cylinder tire pump. The piston is fitted with one large ring and a unit of five small rings. The pump is furnished complete with fittings for any car at $15

The tool is held in the vise and the valves turned with a brace. There is an interior chuck which closes on the valve so that it cannot chatter while turning and an adjustable bearing takes the end thrust. Both are adjustable.

The cutters are 45 deg. at one end and 60 deg. at the other, being adjusted by means of a micrometer screw. The seating cutters, of milling cutter type, have from sixteen to twenty-four teeth, according to size, and are so constructed that a cutter ¼ in. larger than the valve will enter the port; the large size permitting the removal of shoulders. The guides are of hardened steel set in a taper. With the port steadyrest having a running thread on a taper which will allow for any size port. The cutter is held in alignment by six ball bearings. The price is $35. For a special Ford set the price is $10.—Healy Tool & Appliance Co., Buffalo, N. Y.

Stewart Tire Pump

The improvements in the Stewart single-cylinder tire pump were described in these columns last week, but through an error the illustration appearing with this article was not that of the Stewart pump, which is reproduced in its improved form herewith.

Chicago Flexible Tubing

A comparatively new product is the Everlasting gasoline hose, which is built up of no less than eight layers. The inner lining is of flexible steel, over which is a layer of fiber, then a layer of braid, one of a special gasoline-resisting composition, another braid, then a second gasoline-proof coating, a third braid and finally the waterproof outer jacket, which is woven on. No rubber is used. Other products include hot air hose for carbureter connections, oil, air and steam tubing, acetylene tubing and connectors, etc.—The Chicago Tubing & Braiding Co., Chicago, Ill.

Coronum Metal Cement

To stop leaks in pipe connections, radiators, boilers, heaters, flanges, etc., Coronum metal cement has been introduced. This cement can be successfully applied without experience by following the directions printed on the cans and is claimed to repair any leak and harden thoroughly within 30 minutes. It is put up for the trade in 1, 5, 10 and 25-lb. packages with the necessary liquid for making the mixture.

It is not affected by vibration and is tested to 500 lb. hydraulic pressure to the sq. in.; on live steam to 250 lb.; on gasoline to 200 lb.; and on hot oil to 500 deg. To repair a hole or small leak in a pipe, fill up the hole or leaking part with a mixture of the cement as thick as putty. Price per pound, $1, including can of cement and can of liquid.—Coronum Equipment Co., New York City.

Los Angeles Sales Gain 117½ Per Cent

Maximum Increase of Individual Dealers' Business Over First Half of 1914 Is 5.38 Per Cent, with 5 Per Cent Gain as the Minimum

By A. G. Waddell

LOS ANGELES, CAL., July 30—An increase of 117½ per cent in the volume of business done from Jan. 1 to July 15 of this year over the same period of 1914 is reported by the motor car dealers of Los Angeles. The minimum increase of the Los Angeles dealer is slightly under 5 per cent. The maximum increase for the period is 538 per cent.

In estimating the increase in the volume of automobile business, fifty-five different makes, forty-six of which are pleasure cars, were used as a basis for the figures. The nine commercial cars figured separately, show an increase of 135¼ per cent, which proves the claim to prosperity made by practically all lines of wholesale and retail trade in southern California. But the gain in the sale of pleasure cars is of the greatest importance. This remarkable gain in pleasure car sales represents $10,000,000 since Jan. 1.

47,000 Cars in Los Angeles County

Los Angeles county owns 33¾ per cent of the cars and commercial vehicles registered in the State of California. There is an increase of 4758 cars in Los Angeles county for the first 6 months of 1915 over the first 6 months of 1914, which is a gain of 48 per cent. There are approximately 47,000 automobiles owned in Los Angeles county to-day.

In California, during the first 6 months of 1915, 137,500 cars were registered. This shows a gain for the entire State of almost 50 per cent.

There is not one county in Southern California which has not gained from 30 to 80 per cent.

Control Southern California and Arizona

The Los Angeles automobile dealers control most of the Southern California and Arizona territory, with sub-agents representing them in the cities and larger suburban towns.

The Chevrolet branch here sold more cars at retail last month than in the whole first six months of 1914. In June, 1915, sixty-four Chevrolet models were sold at retail by the Los Angeles branch of the Pacific Coast agency. With 1200 cars contracted for 264 have been sold out of the local house during 1915 against forty cars delivered during the same months of 1914.

The Overland shows an increase of 77 per cent over last year's business to July 15. The J. W. Leavitt Co. branch here has sold and delivered 1172 cars this year.

The Winton Motor Car Co. shows an increase of 50 per cent for the Los Angeles factory branch.

The Chandler agency shows an increase of 108 per cent which represents $225,000 in sales.

An increase of 37 per cent has been made by Don Lee, Cadillac and Paige dealer. This is a gain which is expressed as $280,000 on the books of the agency.

A remarkable gain of 112 per cent is shown by Lord Motor Car Co., Maxwell dealer, which has all of Southern California and Arizona. Both the National and Oakland sales of Hawley, King & Co. have increased 35 per cent.

The Peerless and Premier being handled by the same firm, Smith Bros., the figures of the two makes are together and an increase of eighty-one cars for 1915 over the 1914 period gives a percentage as ninety-eight in the increase column.

For the Bekins-Spears Motor Co., Haynes dealer, the gain has been 101 per cent.

The Beardsley Electric Co.'s books show a gain in sales of 60 per cent and the Benrich Motor Co., Moline dealer, has a gain of 50 per cent.

The Apperson Motor Car Co. sold and delivered fifty-four cars in the period last year, and up to July 15 of this year 151 cars had been sold. The Apperson's territory has just been increased to embrace the three States, California, Arizona and Nevada and for the past thirty days the salesmen have been taking orders only, as no cars were to be had for delivery.

One of the chief difficulties of the Los Angeles automobile man is the scarcity of cars. The demand greatly exceeds the supply. On the sales floors of many of the largest houses in this city, there is but one show car and some dealers have sold even their show cars and demonstrators.

For some of the early season models owners have paid bonus prices and for one car delivered among the first of the 1916 arrivals, $350 was added to the original price as the dealer wished to retain the car for a demonstrator.

F. R. Cryiacks, Buick dealer, now has more than 800 orders on file and cars are coming through from the factory at Flint, Mich., in four, five and six-car-load lots every day or so; but the orders continue to roll in ahead of the deliveries.

The Cole Motor Co. shows an increase of 65 per cent but the increase would have been greater had the agency been able to deliver the cars. Four car-loads arrived here July 19 and there was but the one demonstrator at the agency the next afternoon. There is almost a motor car panic on in Los Angeles to-day.

Great Gain in Truck Business

Among the truck agencies showing a great increase in business during the early months of 1915 is the local Moreland factory. This concern has doubled its business twice during the past year and the capacity of the plant is now being enlarged to accommodate a 100 per cent increase in business. The month of June, 1915, was the greatest month of the Moreland plant. During the month there were fifty-seven trucks built and delivered.

For the periods of the two years, the Mack Motor Truck Co., agents for Mack, Saurer and Republic trucks, shows an increase of 133½ per cent.

The Commerce truck has increased the truck total for Los Angeles this year. H. G. Pendell, local distributor, has an increase of 150 per cent to his credit but this cannot be taken into consideration in the general average as he did not have the agency during the first months of 1914.

White deliveries have not increased at the same rate as other makes but in volume of business the White shows a 50 per cent gain with a business here as solid as a national bank. Kissel and Federal have a joint increase of 47 per cent which means a great deal for such heavy sellers in this territory. The Kelly-Springfield has an increase of 71 per cent this year which is due to a steadily advancing demand for commercial vehicles of the type in Southern California.

Determining What's What

IT needs a gathering of service men and a few hours' talk to understand how many pieces of an automobile can be called by half a dozen names or more. It needs a discussion to show how many reasons there are why each name is the best from a particular automobile manufacturer's viewpoint, and, one may add, it needs some very progressive men to make as much progress as was made by the informal nomenclature meeting held in Detroit last week.

There is a sufficient similarity between each detail of any one automobile chassis and any other to make possible the use of the same name for the same part, or for the part which does the same work. To settle on one name and discard a dozen alternatives means time and concentrated effort by those intimately interested, but if twenty men gave six months entirely to the subject their aggregate labor would be less than that which is wasted in a week by the thousands of people who handle replacement parts.

The nomenclature work of the S. A. E. has not made the progress it might have made, on account of the tremendous difficulty of the subject, but the new scheme of working should clear the matter up quickly. We look forward to an early future in which the chaotic terminology of the present will be replaced by the most complete and perfect technical language possessed by any industry.

Provoking Invention

WHEN the Knight sleeve-valve motor was first taken up and standardized by a British maker it provoked a tremendous boom in invention and experiment with gasoline engines having sleeve, piston or rotary valves. It is safe to predict that the adoption of the Knight motor for a car which will be produced in large quantities is sure to have a similar effect. The stimulus to inventive thought created by the Knight motor's first appearance as a European product spread all over the mechanical world, and was not confined to Europe, by any means; so there are many half-developed ideas lying dormant in America which have never been exploited or even tried out.

A boom in any sort of invention is usually productive of a few excellent things, even though the mass of boom inventions are utterly worthless; so it seems likely that a re-awakened interest in motor valve systems may lead some of the languishing ideas to be resuscitated. With the valve situation so shaken up as it has been by the success of multi-valve racing motors the whole subject is ripe for renewed experiment. We know much more about materials and about lubrication than we did in 1906, and it is possible that some good motors which were impracticable then would be satisfactory now.

Useless Metal

WHAT man would try to ride a bicycle weighing 100 lb.?

Surely, only a crazy man, and yet many a gasoline motor is being asked to do something equally absurd. The motor does it because it is strong enough, but it does it only at the cost of more fuel, oil and tires than would be used to carry a lighter load. Carrying on the bicycle analogy, the vehicle here weighs less than one-fifth as much as the load it carries. The automobile, on the other hand, weighs more nearly five times as much as the load.

Of course, the cases are different, as the automobile load does not supply its own power, but the fact remains that only one-fifth of the power of an automobile engine is available for the transport of the passengers, the other four-fifths goes to the transport of the car itself. Surely four-fifths is a very large fraction?

The automobile has been given reliability and a wonderful flexibility of power that is best called roadability. Throughout its development the word efficiency has been used loosely with reference to all sorts of things, but we have now reached the stage where the only real efficiency may be studied. Real efficiency in the broadest sense means work done by comparison with cost of doing it, and the first step along the road of progress is to cut out some of that four-fifths of dead metal. It is no impossibility; merely it means the use of more suitable materials and a better proportioning of stresses throughout the structure as a whole. Let every part help to carry itself instead of having some other part to bear its weight.

Overland Forced to Expand

To Add 23 Acres of Floorspace —New Office Building —Orders Plentiful

TOLEDO, OHIO, Aug. 2—Additions more than equalling the size of the average American automobile plant are being started at the Overland factory here. According to officials of the company, the additions to the factory alone will be equivalent to almost 23 acres of floorspace. In addition to the factory extensions, there will be a new office building 63 by 373 ft.

One of the new factory structures will contain 20 acres of floorspace and will be nearly three times the size of the original Pope plant, when taken over by John N. Willys, president of the Willys-Overland company. This building will be five stories high, 400 ft. wide and 400 ft. deep. It will be used for final testing, body assembling and finishing and will contain 800,000 sq. ft.

The enameling department will have an extension put on it containing 3500 sq. ft. of floorspace.

The pattern shop will be enlarged by a three story, fireproof addition, 83 ft. wide by 100 ft. long. This new building will add 25,000 sq. ft. of floorspace to the department. The dry kiln building will be increased in size by a two story, fireproof extension 145 ft. by 107 ft. containing 31,000 sq. ft. of floorspace.

The original Pope buildings facing Central Avenue will be rebuilt and enlarged by 53,000 sq. ft. of floorspace. They will be made fireproof throughout.

The old wooden buildings will give way to a new administration building. The plans call for a seven story fireproof structure, made of steel and tile throughout and containing 165,000 sq. ft.

Although the production of the Overland company is larger than ever before in its history, and is steadily increasing, the factory finds it impossible to gain on the orders pouring in from all sections of the country.

McDuffee Overland Sales Mgr.

TOLEDO, OHIO, July 31—Joseph H. McDuffee, who was recently put in charge of the Willys-Knight division of the Willys-Overland Co., has been appointed assistant sales manager of the entire organization.

Richman Cole Factory Manager

INDIANAPOLIS, IND., Aug. 2—J. F. Richman, formerly factory production manager of the Cole Motor Car Co., has been promoted to factory manager. Mr. Richman has been with the Cole company for almost three years, coming from the Hudson Motor Car Co. after being with that concern for four years. Previous to that time he was with the Oscar Lear Co., Springfield, Ohio, since changed to the Kelly-Springfield Motor Truck Co. Prior to that time he was connected with the Oldsmobile company for a number of years.

S. A. E. Standards Committee Meeting Scheduled for Oct. 14

NEW YORK CITY, Aug. 3—The date for the standards committee meeting which, as has been announced in THE AUTOMOBILE, will be held in Chicago, has been set for Thursday, Oct. 14. The meeting will occupy but one day and will be in the nature of a convention, as members of the society from all over the country will be in attendance. All members of the society are welcome to these meetings and this one will be of particular interest to those around Chicago as it will probably mark the introduction of a Chicago section of the Society which will have its own meeting place and officers.

Paterson Has New Six

DETROIT, MICH., Aug. 4—*Special Telegram*—The W. A. Paterson Co., Flint, Mich., is bringing out a new light six at $985 for the five-passenger and $1,060 for the seven-passenger model.

The motor is a Continental, 3¼ by 4¼ in. Wheelbase is 117 in. and tires are 32 by 4. The carbureter is a Stromberg.

The four-cylinder model will be continued and is the same, except in minor details. The price of this car is reduced from $1,095 to $985.

Grant Brings Out New Six

FINDLAY, OHIO, Aug. 2—The Grant Motor Co. has brought out what is known as model TT Grant six. It is not a 1916 model but rather a summer series model. The only difference between the TT and the T model is that the former has a motor with 3 in. bore while the latter has 2⅞ in. bore. In the model T a Mayer carbureter was used, but the TT has a Rayfield. In other constructional or equipment features the two cars are alike and the price also is the same.

Rumely Co. to Enter Small Tractor Field After Reorganization

SOUTH BEND, IND., July 31—It has been announced by J. W. Toone, treasurer of the M. Rumely Co. of Laporte, that after the reorganization of the company it will enter the small tractor field, and Mr. Toone also took occasion to deny the rumor that Henry Ford of Detroit was negotiating for the Rumely oil pull plant.

Timken Axle Officers Promoted

H. H. Timken Is Board Chairman—Alden and Lewis Vice-Presidents

DETROIT, MICH., Aug. 2—Promotions and changes have taken place at the Timken-Detroit Axle Co. recently, among the officers. Former Vice-President H. H. Timken has been appointed chairman of the board; W. R. Timken remains president of the company; A. R. Demory, production manager; H. V. Alden, chief engineer and Eugene Lewis, formerly secretary-treasurer, are appointed vice-presidents, and Mr. Lewis is also made general manager. Assistant Treasurer C. W. Dickerson is now treasurer; F. C. Gilbert, who was assistant secretary and sales manager, is promoted to be secretary and retains his other title; W. H. H. Hutton, Jr., who was purchasing agent, director of purchasing.

E. B. Lausier, who represented the Timken-Detroit Axle Co. in the East has resigned and George L. Bitting, who formerly traveled the central States, has taken his place. He has his headquarters in Buffalo and covers the territory including Cleveland, New York and Eastern Canada.

P. W. Hood, with headquarters in Chicago and Detroit, continues to represent the Timken-Detroit Axle Co. and the Timken Roller Bearing Co. in the West, but in addition he will represent the Timken-Detroit Axle Co. in Southern Michigan.

Harry J. Porter, Detroit, formerly representing both Timken companies in Southern Michigan now represents the Timken Roller Bearing Co. in that territory, Ohio, Indiana and the South.

C. E. Gordon, Indianapolis, formerly representing the two Timken concerns in the Central West now represents the Timken-Detroit Axle Co. only, with headquarters in Toledo, Ohio.

Willems Off to Antipodes

DETROIT, MICH., Aug. 2—E. G. Willems, foreign district representative of Dodge Bros. will start shortly on his second extensive foreign tour which will extend over a period of at least six months. Sailing from San Francisco Mr. Willems will first go to the Hawaiian Islands, then to Australia, New Zealand and other countries in that vicinity.

Kiser Chalmers General Auditor

DETROIT, MICH., Aug. 2—William P. Kiser, formerly secretary of National Cash Register Co., Dayton, Ohio, has been appointed general auditor of the newly organized general auditing department of the Chalmers Motor Co.

Foreign Field for Parts Makers

Maxwell Export Representative Says Europeans Are Taking to Assembly

[illegible], MICH., Aug. 2—J. B. Crock[illegible] export representative for the Max[illegible] Motor Co. in the Orient, and who [illegible] represents some British motor car [illegible] manufacturers, has returned after hav[illegible]ent some time in Europe trying to [illegible] manufacturers abroad in Amer[illegible]ase parts, motors, transmissions, [illegible]etc.

[illegible]American method of purchasing [illegible]nts from parts makers and then [illegible]ing cars has never met with much [illegible] in Europe until the present war. [illegible]e to the exceedingly great need of [illegible]ars some of the leading British [illegible]kers have decided to try the [illegible] idea and if these manufactur[illegible] successful in their experience [illegible]erican parts, it is thought that [illegible] new field will thus be open for [illegible]rican parts makers.

[illegible] present time there is no credit [illegible]tion and the purchases made [illegible] Crockett are paid for in New [illegible]. One of the principal things which [illegible]rican manufacturers must bear [illegible] in order to get the business and [illegible]faction, is to make deliveries [illegible]d and also to adapting their [illegible] as far as that is possible to the [illegible] requirements. The matter of [illegible] up with promises of deliveries [illegible]portant. Manufacturers inter[illegible] communicate with THE AUTO-[illegible].

—

[illegible]oreign Trade Department

[illegible], MICH., July 29—No special [illegible] been made thus far by the Olds [illegible]rks to get foreign business [illegible]e demand by American deal[illegible]ve always taken practically the [illegible]al output. Since the begin[illegible]e European war automobile [illegible]oreign countries have inquired [illegible]d a good many have even [illegible]e factory to try and secure [illegible]hat the Lansing concern has [illegible] reserve part of its production [illegible]r foreign markets. A special [illegible] department has been estab[illegible]hat purpose. It is in charge [illegible] Zimmerman.

—

[illegible]es Scarce in Norway

[illegible]IA, NORWAY, July 30—Rub[illegible]me so scarce in Norway that [illegible] public automobile traffic is [illegible]mpered and a great number [illegible]ve had to be taken off the roads [illegible] arrangement can be made for obtaining tires from abroad. On several routes the tourist service by motor omnibus has been stopped entirely.

The Royal Automobile Club and the Foreign Office are endeavoring to obtain permission from England to purchase limited quantities of manufactured rubber in London.

—

International Motors Raises Wages 20 Per Cent.

PHILADELPHIA, PA., Aug. 2—An eight-hour day and a 20 per cent. increase in wages to the 1200 employees of the International Motor Car Co., has been announced at the company's offices at Allentown, Pa. This big concession has come in the form of a "war bonus" because of the large orders, said to aggregate $5,000,000, the company has for motor trucks for use in the war. Approximately 600 men are employed at the Allentown plant, and about the same number at the works in Plainfield, N. J.

—

Locomobile Will Share Profits

BRIDGEPORT, CONN., July 31—Notice was given to its workmen by the Locomobile Co. of America, to-day, that a plan has been adopted to share the profits of the company with its workmen by means of wage increases in proportion to the increase of product.

The plan of the Locomobile company embraces all the workmen, from the sweepers to the departmental foremen and is said to be arranged on a bonus system of $60 per car. The scale is a sliding arrangement which allows each of the workmen a pro rata percentage. Thus for fifty cars there would be $3,000 distributed among the men. In case of turning out more than sixty cars per week the bonus changes. For sixty-one cars it would be $61 per car and for seventy cars it would be $70 per car and so on.

—

Ten Per Cent Wage Increase for 500 Men in Autocar Plant

PHILADELPHIA, PA., July 31—According to a notice posted about the factory buildings of the Autocar Company of Ardmore, Pa., to-day, and signed by Walter Norton, vice-president and production manager of the company, employees of the concern are to receive a voluntary increase of average 10 per cent in wages accompanied by a reduction in working time of forty-five minutes daily. All overtime work will be recompensed on the basis of time and half time. About 500 men are affected.

—

Monahan Leaves Gibson Co.

INDIANAPOLIS, IND., Aug. 2—J. R. Monahan who has been closely affiliated with the Gibson Co. here, in an official capacity has resigned to become a commission broker.

Canadian Ford Cars $60 Lower

Runabout $480, Touring $530, and Town $780—No Rebate Up to Aug. 1

DETROIT, MICH., Aug. 3—For 1916 the new Canadian Ford prices are reduced $60, the prices now being $480, $530 and $780, respectively, for the runabout, touring car and town car. No speedometer is included at these prices. During the three next months no rebates are given but if conditions change and warrant it a rebate may be announced later.

Because the Ford Motor Co. of Canada, Ltd., sold only 18,774 cars during the fiscal year ending Aug. 1, the buyers of these cars will not receive a rebate which had been made conditional upon the sale of 30,000 cars during the fiscal year. While the Canadian business was practically uniformly good during the year, the foreign business which has always been a very important part of the Canadian plant, has dropped considerably, owing to the European war.

—

Knox Resigns from Lyons Atlas

INDIANAPOLIS, IND., July 31—H. A. Knox has severed his connection as general manager of the automobile department of the Lyons Atlas Co., and temporarily will return to Springfield, Mass.

—

Wheeler Paige Production Manager

DETROIT, MICH., July 30—W. A. Wheeler has been appointed production manager of the Paige-Detroit Motor Car Co., succeeding James F. Bourquin, who resigned last week, as reported in THE AUTOMOBILE for July 29. The Paige company has a production schedule of 20,000 cars for this year.

—

Scheu with Star Refining Co.

NEW YORK CITY, Aug. 3—E. A. Scheu, recently connected with the sales departments of Charles F. Kellom, Philadelphia, and the Invader Oil Co. of New York, has joined the sales department of the White Star Refining Co., Detroit. Mr. Scheu will make his headquarters at the Detroit office.

—

Hawkins Goes West for Midgley

LANCASTER, OHIO, July 31—The Midgley Tire & Rubber Co. this city has made arrangements with C. A. Hawkins of San Francisco to make an extensive tour throughout Western Coast States in its interests. Mr. Hawkins was for several years western representative of the White Co.

It is expected that agencies will be established in all of the principal cities on the Western Coast.

A. A. A. Gasoline Price Inquiry

Nation-Wide Investigation Planned—Report in October—Oppose Intercity Speed Tests

ERIE, PA., Aug. 2—At the conference of the executive committee of the American Automobile Association held here a nation-wide investigation of the price of gasoline was determined upon and Louis R. Spear, of Boston, was appointed to conduct the inquiry with instructions to report in October.

Gasoline made its first jump in several months on the New York market this week, going up 1 cent. This rise the Standard Oil officials ascribe to increased summer demand and market conditions.

The committee also recommended that the by-laws of the organization be revised to conform with State regulations and declared itself opposed to speed tests between cities, principally Philadelphia to New York and Boston and from Chicago to San Francisco. The committee also approved reciprocity with Canada on the question of allowing American registered cars to be operated in Canada without taking out a Canadian license. Representatives from Massachusetts, New York, New Jersey, Pennsylvania, Ohio, Indiana and Illinois attended.

Uniform Gasoline Prices in Oklahoma

OKLAHOMA CITY, OKLA., July 30—Gasoline retailers must establish uniform prices throughout the state, according to an order issued by the corporation commission in which citizens of Poteau charged the Pierce Oil Corp., the Gay Oil Co., The Texas Co. and the Magnolia Petroleum Co. with discriminating between cities in the eastern part of the state. When gasoline was selling for 16 cents a gallon in Poteau in May it was alleged by the complainants the same companies were marketing it at McAlester for 12 cents, at Muskogee for 12 cents, at Hugo for 12½ cents, at Bartlesville for 11 cents, and Fort Smith and Greenwood, Ark., for 12 and 11 cents respectively.

Hartford Electric Brake $90

JERSEY CITY, N. J., July 29—The Hartford Suspension Co. has materially reduced the price of its Hartford electric brake. The complete apparatus heretofore was sold for $150, but hereafter the price will be $90.

Hoosier State Association Formed

INDIANAPOLIS, IND., Prominent citizens of Indianapolis, most of them members of the Hoosier Motor Club, Friday filled papers of incorporation for a new organization to be known as the Hoosier State Automobile Assn. The new body plans to organize the motorists and good roads enthusiasts in all of the principal cities and towns throughout the State into local clubs. It will be affiliated with the American Automobile Assn. H. W. Patton, recently elected to the position of secretary of the Hoosier Motor Club, is the prime mover in the new organization.

Motion Pictures Show Bearing Manufacture at SKF Plant

NEW YORK CITY, July 29—P. G. Prytz, a representative of the board of directors of the Swedish factory of the SKF Ball Bearing Co. has brought over to this country a reel of motion pictures showing the buildings and work at the Aktiebolaget Svenska Kullagerfabriken, which is the Swedish name of the factory known in this country as the SKF Ball Bearing Co.

The pictures were shown to-day to a number of the American officials of the company and a group of representatives of THE AUTOMOBILE, and are remarkable in that they show that rapidity of development and system in plant layout are not peculiar to America. Since the route of travel between Sweden and this country lies outside the war zone none of the difficulties that have beset many of the importers of ball bearings have troubled the SKF company. Not indirectly due to this the plant is at present working at its full capacity and is constantly adding new buildings. The present force of men numbers 3000, and the small building which in 1907 represented the SKF factory is now almost lost to sight among the rows of huge buildings which are devoted entirely to the manufacture of ball bearings. The bearings are made for practically every use to which ball bearings can be put.

Invents Four-Wheel-Drive Truck Using Chains

GOSPORT, IND., July 31—Claude Hoadley, of this place, has built a four-wheel-drive gasoline truck on which he holds U. S. Patent No. 1,027,730. The four-wheel-drive feature as incorporated in this truck employs chain-drive to each of the four wheels, all of which are used for steering. Each axle and jackshaft group is mounted on a fifth wheel device, the same as the front axle of a horse-drawn vehicle, the conventional motor truck steering knuckle not being used. When either axle is turned the complete jackshaft and transmission system turns with it. The motor is carried in front and there is an ingenious system of power transmission from it to the front and rear jackshafts employing four universal joints and bevel and spur gearing. The steering of the front fifth wheel is through a rack and pinion.

Registrations Reflect Sales Boom

Ohio Has 161,700 Cars and California 144,500—Other States Show Gains

COLUMBUS, OHIO, Aug. 2—W. H. Walker, Ohio registrar of automobiles, has made a report covering the present year up to July 30, showing a total of 161,700 motor cars registered since the first of the year. The total registration for the whole of 1914 was approximately 122,500 which shows quite an increase for the present year. It is estimated that 175,000 cars will be registered in the Buckeye State this year.

Chauffeurs to the number of 13,643 have been registered by the department.

144,500 Cars in California

LOS ANGELES, CAL., July 27—California's motor car registrations for 1915 have reached a total of 144,500 according to the latest figures announced by the State motor vehicle department. It is claimed that this number will be greatly increased next month when the license fees are reduced 50 per cent. W. S. Goble, superintendent of the Southern California branch of the State motor division with offices in Los Angeles, predicts 150,000 registrations for the State before fall.

21,305 Is Washington's Total

OLYMPIA, WASH., July 30—The 21,305 licenses thus far issued by I. M. Howell, Secretary of State of Washington, are classified as follows: 15,842 privately owned automobiles; taxicabs, jitneys, etc., 1690; privately owned trucks and delivery cars, 1071; trucks and delivery cars for hire, 153; automobile stages, 183; dealers' demonstration machines, 183; exempt cars owned by State or cities, 49.

15,925 Cars in Kentucky

FRANKFORT, KY., July 29—Since the first of the year 15,925 automobile licenses have been issued in Kentucky, 4168 more than during the entire year 1914. Applications for licenses continue in large numbers. Motorcycle licenses to date number 1185.

208 Postal Automobiles Start

WASHINGTON, D. C., Aug. 2—Two hundred and eight automobile rural postal delivery routes distributed among eight States will start operation to-day. This means that approximately 11,440 miles of rural roads will be traveled six days a week during August by postal automobiles. In all orders have been issued authorizing 298 motor routes, varying from 50 to 64 miles.

Plants Rushed—Sales Boom Continues

Car and Accessory Factories in Detroit Report Orders Pouring In—Retail Sales Gain in Nearly All Quarters in Spite of Rainy Weather Though Chicago and Kansas City Markets Are Slowed Up

DETROIT, MICH., Aug. 2—Last week, not only was there no falling off in the demand for automobiles and parts in the Detroit district, but the pressure seems actually to be increasing. Many of the parts plants are running almost continuously, as instance the Detroit Steel Products Co., which is working three shifts with a total loss of time of only 33 min. in twice around the clock.

Automobile makers continue to be far behind on shipments and orders are still pouring in by every mail. The conditions in New England seem to be restored to normal, by proportion with the rest of the country, and it is to be noted that the South is noticeably waking up and demands are coming in from the cotton districts in a most encouraging way.

Continental Motor is commencing to occupy the new building at Muskegon, but despite this, and the second building to be ready next month, the company has orders on hand to keep the plants at full capacity till well into the winter. Bower roller bearings are being called for at double the rate for the corresponding period last year and the Gemmer Mfg. Co. considers trade to be 80 per cent better, the factory running night and day to meet the demand.

The King Motor Car Co. reports a particularly strong demand for eights from England and is shipping cars abroad every day. This experience tallies with that of the Cadillac company which has found the eight much appreciated in England and is doing an extremely satisfactory business through its London representative.

Metropolitan Territory Wants More Cars

NEW YORK CITY, Aug. 3—If it were possible to get all the cars that could have been sold in the metropolitan district during the month of July, that month would have broken all previous records for motor car sales, according to the sales managers of the representative local branches and agencies. All the well-known concerns in all price classes are selling all the cars they can ship and while deliveries are not in such bad condition that the purchaser has to wait more than three or four weeks, still the lack of facilities for deliveries on the spot has prevented a number of sales that could have been made.

Sales Ahead of 1914

With this condition of a steady rush to fill the incoming orders, it is small wonder that sales are ahead on all sides as compared to what they were a year ago. Furthermore, July, instead of being far below June as a selling month, as has been the case in previous years, is practically on a par with it.

Speaking of Overland sales, for instance, officials of the C. T. Silver company state that they can sell all the cars that can be shipped by the hard-pressed factory. July, they state, is somewhat below June in the total volume of sales, as would be expected, but the percentage of business as compared to a year ago shows a strong advance. Ford is 135 per cent ahead of a year ago in volume of sales, Buick is 300 per cent of a year ago, according to sales manager Newton, and the cars coming through this month will probably number 400. The largest demand is of course for the smaller of the two sixes, the proportion of sales being about the same as the factory manufacturing schedule, i.e., five small to one large car. Hupmobile estimates that the metropolitan sales are just double what they were a year ago, with July as the best month ever had by the local distributer, Chas. E. Riess. At the present schedule of orders 100 cars a month are being shipped. Chalmers is doing at least one-fourth more business now than a year ago.

Delivery the Big Problem

It is not only in the lower and medium-priced cars that the sales are booming. The Pierce-Arrow states that the business of July compares favorably with that done a year ago, the question of delivery being the only one which concerns the company at the present time. The cars ordered now are delivered in September and if they could be delivered more quickly sales would be correspondingly higher. The same story is told by the dealers in higher-priced cars as in the lower: The buyer of to-day is demanding quicker delivery and the reason for this is given by many as directly traceable to the time of the 1916 announcements. However that may be, the fact remains that everyone in the metropolitan district who has cars to sell and can deliver the goods is getting the business and getting all that he can handle. No one is complaining of having been assigned too heavy selling schedule by the home plant.

Rains Slow Up Chicago—Damage Crops

CHICAGO, ILL., Aug. 3—*Special Telegram*—Automobile trade conditions in Chicago territory have slowed up perceptibly during the past week due to heavy rains throughout the territory. For three months unusual rains have fallen, but it is becoming quite serious, as should these continue much longer, the corn crop will be injured. Hot dry weather is needed. Numerous sales in the territory are being held up and several of the Chicago distributors are getting more stocked up with cars than they have been for many months. July was a remarkable month for business with many distributors. Tire business is slower, as touring has been very much slowed up by rain, and the general accessory trade is also beginning to feel the effects of the continual rains. A still more serious aspect of the rains is that in some sections of Illinois the oat crop is being injured, much farm land being under water. In some sections where the crops are harvested, but are still in the field, it is impossible to thresh the grain. Many local dealers with 1916 lines are losing sales every day by not being able to make local deliveries, and this is giving weaker lines a favorable selling season.

Kansas and Missouri Buy Cars in Rain

KANSAS CITY, MO., July 31—What the automobile trade would have been this summer had the weather been normal, is beyond imagination. With rain practically every day, a large portion of the territory overflown by rivers, thousands of acres of crops ruined by floods or rains, roads impassable, and conditions such that cars could not be demonstrated—nearly every line of automobiles reports gains over last year.

Where the cars went to, how they did it, the agents and dealers are unable to say. But the records show for them-

selves—the cars are sold; and the factories know of the insistent demands that could not be met for automobiles, for Kansas and Missouri farmers evidently bought automobiles in the rain, to be prepared to use them when the skies cleared. City people bought machines in the rain and used them on the boulevards.

Largest Sales to Country

Many other lines of business send gloomy reports from the small towns and agricultural districts because of the water damage and consequent general depression. Yet, strangely enough, the largest gains in automobile sales seem to have been in sales to the country. It probably would be a fair statement, based on many inquiries, that the lighter and less expensive cars have been the more popular for the farmers. The Maxwell agency at Kansas City, for instance, seems to have fairly definite data that those light and inexpensive cars have gone with a rush into the country, for the gain in sales is over the whole southwest territory, being a gain of at least 50 per cent over the last two weeks of July in 1914. The Ford gain, too, has been very general over the territory. The Bond Motor Company had a hard record to beat in its tremendous sales of July, 1914—but it has exceeded them. It rather seems that the largest advances over 1914 have been made in the medium-priced cars, however; and this extends to both country and city. The Overland has been selling double the number of cars sent out last year, with a slight advantage for the rural trade. The reduction of price is considered one factor. The Studebaker agency was in its usual fix—sold far ahead, and held back for delivery. The Studebaker office has a close line on territory conditions; one phase of the report is enlightening—that in the spots actually flooded there has been a decrease in sales, but those spots constitute a small section of the territory. One might judge by newspaper reports that both the States were entirely overflowed; but there were many districts practically unaffected by floods. The continued rainfall damaged crops and set back business, but did not cause serious discouragement. The increases were less pronounced in the higher priced cars; but the Oldsmobile showed a steady advance; the Hudson agency is now enlarging its accommodations because of growing business.

Many Substantial Gains

As the prices rise the percentage of increase decreases. Most of the agencies of more expensive cars have held their own, many showing substantial gains. The Buick agency had a 50 per cent increase over last year's business and reports that it might have been 100 per cent had the cars been available. The Chalmers people also report a 50 per cent increase. The Cadillac sold in excess of 25 per cent over last year's deliveries. The Hupmobile agency does not give out definite information, but declares that the sales increase is equal to if not above that of any previous year for five years past.

Of the more expensive cars the Packard people report a 25 per cent increase of sales over the 1914 season, with a tendency to greater demand at this time, during the last days of July, than has been realized earlier in the present season. The Locomobile reports a 35 per cent increase and the Marmon about the same. The Pierce-Arrow has a little better than held its own with last year's record, which those concerned seem to think was very satisfactory considering the financial situation.

The feeling all around is that the past thirty days have shown a marked improvement over sales earlier in the present year.

$600,000,000 Crops in the Minnesota Section

MINNEAPOLIS, MINN., July 31—Figures almost unbelievable in the crop estimates for Minnesota, for the four Northwestern States, and for the ninth federal bank district, will sound as sweet music in the ears of the automobile manufacturer and distributor and the accessory dealers. They give chance for an estimate of what the automobile trade for 1916 will be, considering that the Northwestern farmer is the heavy purchaser of motor cars in this trade section.

Listen to this: The government estimate July 1 of the total of all crops in the ninth district is $600,000,000, or 800,000,000 bushels. This district centers at Minneapolis, where the bank is situated, and extends from the middle line of Wisconsin and Upper Michigan west to Washington State.

$300,000,000 for Wheat

Fully $300,000,000 will be paid to the farmers of Minnesota, the Dakotas and Montana this year for wheat alone. It is expected to be the greatest small grain crop in the district's history, passing even the bumper yield of 1912. With better weather later in the season it is a question whether the corn crop will not be enormous. Rains in even the near-arid districts of the States mentioned have rushed the wheat crop along fast, have prevented rust, and in every way lent aid toward an enormous yield of grains.

The government crop statement for 1912 placed the four-State wheat yield at 282,389,000 bushels and the estimate for July 1, 1915, was 257,402,000 bushels, but experts find there has been a great improvement since the first day of the new fiscal year. The wheat acreage sowed in the four States is 17,330,000 bushels, and would require only a small improvement per acre to make an enormous gain over the federal estimate.

The oats estimate is 266,747,000 bushels, under the 1912 figures, but an improvement has been marked in this grain also since July 1, 1915. The total barley yield is estimated at 87,668,000 bushels, and the flaxseed yield at 15,799,000.

$410,624,000 from Farming

In this connection it must be remembered that the prices for grains are higher than last year, so that the farmer is to receive a sum total in cash greater than last year, both because the prices and the crop are much greater. Wheat, instead of being 70 to 75 cents per bushel, as last year, ranges just now well above the $1 mark. Bumper crops and war time prices furnish the glowing outlook in which the automobile dealer is to participate.

As for Minnesota, farm experts figure that the agricultural returns in new wealth this year will be $410,624,000. This should mean financial and industrial peace and purchasing power. Farming is well diversified in this North Star State. William Magivny, president of the Union Stockyards, South St. Paul, puts an estimated value on hogs to come in in 1915 at $33,000,000. Most of them will come from Minnesota. The estimate is 2,250,000 hogs. Last year the record was only 1,500,000. The cash estimate last year was $19,000,000 at this time, so the present ontlook is for nearly double the valuation of a year ago in live pork. In cattle and calves the expected gain is $11,000,000 for 1915.

In the State the corn valuation loss will be $5,000,000, or 15 per cent, as compared with last year. Increased acreage of wheat reduces barley, rye and hay, and leaves oats at the same as last year. The wheat crop will be $63,000,000. In Minnesota there are 1,186,000 milch cows. It is the bread and butter state of the Union, and to an even greater extent in 1915, because there are 26,000 more milch cows than last year. Low prices will permit an advance of only $1,000,000 in dairy products for this year for the State, but the production is to be $70,000,000.

In potatoes alone the yield is expected to be $10,000,000. The crop has just begun to move. The crop is being financed just now on the basis of 35 cents per bushel to the farmer. Quality and quantity are good. The government estimate July 1 was 275,000 acres planted, which gives a total of 28,303,000 bushels.

Bank Deposits Increase

On top of this the net increase in deposits in State banks for the year ending July 1, 1915, was $10,291,510, to a

total of $49,822,205, to which may be added $12,815,376 savings deposits, $101,195,450 time certificates and $468,-599 in demand certificates.

Population Gains

The directory estimates of the populations of Minneapolis and St. Paul show an increase in one year of 15,319, making Minneapolis a city of 360,357 and St. Paul 276,140. The government census in 1910 placed the population of Minneapolis at 301,408 and St. Paul at 214,744. To give another angle, the government estimate of population for July 1, 1915, is as follows: Minneapolis, [illegible]; St. Paul, 241,999; Duluth, 91,-[illegible]. These are gains respectively of 17.2 per cent, 12.8 per cent and 17.04 per cent. These are the largest of the cities of the State and reflect the gain average prevailing throughout the Northwest. The State's gain in five years is 171,053, or a total of 2,246,761.

Another form of prosperity is to be felt in the State when the Minnesota [illegible] Co. opens its new plant near Duluth, Nov. 1. It is an enormous institution which is to manufacture Minnesota's ore into pig and other products right on the ground. The coke ovens will be in operation Sept. 1.

Cars in Minnesota

In Minnesota, by July 31, a total of 82,-[illegible] motor cars were registered with the Secretary of State at St. Paul, and many more are in sight as the 1916 models are distributed to owners. South Dakota will increase between 20,000 and 30,000 cars, and other Northwestern States correspondingly. In Minnesota this year the Secretary estimates 100,000 cars will be registered. The licenses are for three years.

These figures of new wealth coming are impressive, because the Northwestern farmer finances his own crops now, collect, and having about paid up his indebtedness for land and machinery and cattle, will be ready to buy automobiles again in September, after a drought through July and August while he harvests his crops.

—

Republic Truck Business Grows

ALMA, MICH., July 30—General Manager F. W. Ruggles of the Republic Motor Truck Co. of this city reports that during the fiscal year the company's truck sales increased over 800 per cent, 90 per cent of the total output of the factory being consumed in the United States.

—

August 7 Ford Day in Venice

VENICE, CAL., July 21—The 72 Ford dealers of southern California are to join with the city officials of Venice in making the first annual Ford Day at Venice, August 7, the greatest automobile celebration ever held in this end of the State.

Washington and Oregon Market Good

TACOMA, WASH., July 30—Automobile business throughout the Pacific Northwest, which includes the large centers Seattle, Portland, Spokane and Tacoma, for the week ending July 31, showed a substantial gain over the same period during 1914. The dealers in these centers have looked to the surrounding country for the bulk of their business and have not been disappointed.

In the low-priced field dealers report an increase of 50 per cent over the previous year's business with the Ford car leading, the increase being between 75 and 100 per cent. These dealers are most optimistic, and being able to make prompt delivery, many actual sales result.

Medium-priced cars are finding a ready market, the increase being in excess of 50 per cent over last year's business. The Overland and Dodge are tied for first place in the amount of sales. Although a number of dealers in this class have been forced out on account of conditions, those remaining are staple and their only handicap is slow deliveries. In many cases deposits have been made on Dodge cars ninety days in advance of deliveries.

In the higher-priced field the demand has been limited. The increase, if any, is small. However, buyers with means are investing in cars instead of loaning their surplus money as heretofore. The Cadillac eight has proved most popular in this section.

Improved road conditions in both Washington and Oregon, good prices obtained for berries and wheat, and a slightly better lumber market, have been the chief causes for increased automobile sales in this section. The optimistic reports of dealers have been checked by the increased number of licenses issued to date. Used car dealers report that the demand exceeds the supply. Banks in all large centers have placed their indorsement on automobile paper.

Rocky Mountain Dealers Want Cars

DENVER, COL., July 31—Sales increases ranging from 40 to 300 per cent over the second half of July, 1914, and a common cry on part of dealers that they can't get enough cars to fill their orders, are the leading features of the automobile trade situation in Colorado and adjacent territory in the Rocky Mountain region. And prospects are considered as being highly encouraging for the 1916 season, with a favorable crop outlook in general and a gradual revival of the mining industry in progress. The 1915 season in general shows a business running as high as four times that of the 1914 season for some makes, and several dealers predict another doubling of their sales during the 1916 season. This condition holds true throughout the Rocky Mountain territory covered by Denver distributors generally, which includes Colorado, Wyoming, New Mexico and parts of Utah, Arizona, Kansas and Nebraska.

Gains 25 to 300 Per Cent

In the low-priced field, the last half of July this year shows a sales increase of 25 per cent for the Studebaker and Reo, 50 per cent for Overland, 60 per cent for Ford, 100 per cent for Maxwell, 150 per cent for Metz, 200 per cent for Buick and 300 per cent for Chevrolet. All these lines also show a substantial increase in the total 1915 business over 1914, ranging from 50 per cent for the Studebaker up to 300 per cent for the Metz.

In the medium field, the July comparison shows a gain of 25 per cent for the Franklin, 40 per cent for the Hudson and 80 per cent for the Cadillac. On the entire season basis, the gain has been about 40 per cent for the Hudson, 43 per cent for the Cadillac and 50 per cent for the Franklin.

In the high-priced field, the Pierce business is practically the same as last year and the Packard sales have doubled during the last half of July. Sales in both these lines have been held down seriously by a shortage of cars, the Pierce people getting this week the first car they had been able to place on their floor since April. On the yearly basis, the Pierce has made a gain of 40 per cent and the Packard business has doubled.

Cars Scarce—Orders Many

The Ford assembling plant in Denver has been unable to get enough parts to keep running, and the reduced price announcement is counted upon to give August a heavy gain over the July orders. Prospective buyers have been holding off for this new price. The Buick, Maxwell, Chevrolet, Overland, Studebaker, Reo, Franklin and Hudson are also handicapped by inability to get cars fast enough, and all figure on a heavy business on the 1916 models. There were 652 Buicks sold in Colorado for 1915, as against 370 for 1914, and the 1916 forecast sets the mark at 1000. Similar illustrations of gains and prospective gains could be furnished by several other makes.

—

Disco to Increase Output

DETROIT, MICH., Aug. 2—The Disco Electric Starter Co. has taken necessary steps for increasing its output. Additional machinery is to be installed and the working force increased. Recently the company received a contract for its starters from the Lycoming Foundry & Machine Co., Williamsport, Pa., which makes automobile motors.

Denby Buys Briggs Factory

Truck Maker Secures Buildings and 6 Acres for $63,500—To Move in Soon

DETROIT, MICH., Aug. 2—The Denby Motor Truck Co. has purchased from the Detroit Trust Co., trustee, the property of the bankrupt Briggs-Detroiter Co. for $63,500. This property consists of the factory buildings and about 6 acres of land. The Denby company will move into this plant within the next few weeks.

Detroit Co. Personnel Complete

DETROIT, MICH., Aug. 2—The personnel of the newly organized Detroit Motor Car Co. is now completed, and consists of Alfred O. Dunk, president and general manager; Wallace C. Hood, general sales manager; H. B. Merrill, assistant general manager and factory superintendent; Robert T. Yeats, director of exports; Frank M. Eldredge, advertising manager; T. J. Holihan and W. S. Yale, purchasing agents.

Can't Use Akron Tire Co. Name in Pennsylvania

PHILADELPHIA, PA., Aug. 2—Judge Sulzberger in Common Pleas Court No. 1 issued a preliminary injunction restraining the Akron Tire Co., of New York, from using that name within the State of Pennsylvania. The suit was brought by the Akron Tire Co., Philadelphia, dealer in tires made at the factory at Akron, Ohio.

Pennsylvania Wins Vacuum Tread Suit

WILMINGTON, DEL., July 31—The Pennsylvania Rubber Co., Jeannette, Pa., won its suit here this week in regard to the sale of Dreadnaught Vacuum Tread seconds. Judge Bradford held that the Pennsylvania concern was entitled to an injunction prohibiting the sale of Dreadnaught Vacuum Tread seconds without the words "Made by the Dreadnaught Tire & Rubber Co." in raised letters on the side of each tire unless the words "Vacuum Tread" be obliterated. The Dreadnaught interests are also enjoined from directly or indirectly stating that their seconds are those of the Pennsylvania company.

The vacuum tread of the Dreadnaught tires differs from that of the Pennsylvania in the design of the cup, the latter being shallower than the Pennsylvania cup and having a bar across the depression. The suit was in the U. S. district court for the district of Delaware.

Steel Market Strong

NEW YORK CITY, Aug. 3—The steel market for last week continued strong, with a large demand for high-grade steel for war munitions more pronounced. There was heavy trading and on Thursday the prices on steel made an upward trend. Bessemer steel made a small gain of 50 cents while that of open-hearth steel rose from $22.50 to $25, a total rise of $2.50. The operations of the steel mills are above 90 per cent capacity. The copper markets still remain dormant with very little trading going on. There are no inquiries from either domestic or foreign sources. The production is expected to be maintained over the month of August. In some quarters it is expected that the record-breaking figures of July will be excelled by the August output. Gasoline market prices took a jump of 1 cent a gallon, making local deliveries 13 cents. This is the first jump gasoline has taken in several months. The tin market advanced a quarter of a cent yesterday on heavier deliveries on consumption. The upward tendency noted yesterday caused some consumers to cover, but buying did not reach large proportions, most of the consumers being fairly well supplied. The rest of the metal markets remained dull with very little trading. The market for crude rubber lacked new features yesterday. Trading continued quiet.

$4,467,453 for Paris Bus Co.

French War Dept. Compensates for Vehicles Requisitioned—No Buses in Paris

PARIS, July 18—The sum of $4,467,453 is the global indemnity paid by the French War Department to the Paris General Omnibus Co. for vehicles requisitioned since the outbreak of war. As the omnibus company had 1120 motor omnibuses in its eleven garages at the outbreak of war, and as all of these were seized immediately, the average price per motorbus works out at $3,988.80. In reality, however, the price per bus is lower than this, for the army seized the bus company's big stock of benzol, spare parts and spare tires.

The arrangement between the French government and the Paris General Omnibus Co. was that as soon as mobilization was declared the entire fleet should pass into the hands of the military authorities. Thus, when the army order was posted on the afternoon of Aug. 1, 1914, the whole of the buses on the streets returned to their depots and were converted into meat wagons. This work was done in the omnibus company's own body shops and was carried out with such rapidity that within 48 hr. not a motor bus remained in the city of Paris. After a year's active service the army authorities declare themselves thoroughly satisfied with the results obtained from the Paris bus.

Holds Exclusive License

As the Paris General Omnibus Co. holds an exclusive concession for motor bus and trolley car service in Paris, it has been impossible to run any motor bus service within the city since the outbreak of war. A new type of bus has been designed and 100 have been built, but they were immediately requisitioned by the army authorities. There is no hope of the bus service being re-established before the beginning of next year.

Up to the year ending Aug. 1, 1914, the Paris motor buses carried 151,919,920 passengers, being an increase of more than 5,250,000 over the previous year. The bus mileage was 14,513,029, an increase of 382,372 miles, and receipts were $4,268,912, the receipts per mile being 29.414 cents.

Kalb a Kelly-Springfield Engineer—Guilder Factory Manager

SPRINGFIELD, OHIO, July 31—Louis P. Kalb has joined the engineering department of the Kelly-Springfield Motor Truck Co., this city and Walter C. Guilder has been appointed factory manager.

Mr. Kalb was in the designing and experimental department of the Pierce-Arrow Motor Car Co. for the past three and a half years and before that with the Garford Co.

Mr. Guilder was with the Mack Motor Car Co., now the International Motor Co., for several years and more recently with the production department of the Timken-Detroit Axle Co.

—

Paige 5 per Cent Dividend — Capital Increased to $1,000,000

DETROIT, MICH., Aug. 3—The Paige-Detroit Motor Car Co. has declared a cash dividend of 5 per cent for August, to be paid on the total new capital of the concern, that is $1,000,000. This dividend will be paid Sept. 10 to stockholders of record Aug. 31. Officials of the company hope that the company will be able to pay a similar monthly dividend, or higher, hereafter. Thus far this year the Paige company has paid 40 per cent on its original capital stock of $250,000.

—

Dividends Declared

AKRON, OHIO, July 31—The B. F. Goodrich Co., has declared the regular quarterly dividend on the preferred stock which amounts to 1¾ per cent, payable Sept. 1 to stockholders of record Sept. 20.

—

Emerson Business Gains 55 per Cent

NEW YORK CITY, July 30—The Emil Grossman Mfg. Co.'s business this year is running ahead 55 per cent more than in any previous year. Plans are being laid for increasing its output.

Securities Markets Are Dull

Tire Issues Are Lower—Changes Range from Quarter to Eleven Points

NEW YORK CITY, Aug. 3—The securities markets were in a sensitive condition throughout last week as a result of the passing of the U. S. Rubber dividend on Friday. The markets were in a very weak and dull condition all of last week. The gains were few and small, ranging up to 11 points, this being Swinhart's figure. Losses were also small, ranging to 2½ points. Tire issues last week were somewhat lower, Goodrich, Miller and Swinehart being the only ones to show increases. Miller Rubber preferred rose 8 points, with no change in common. Swinehart showed the largest gain when it took a rise of 11 points above that of last week. U. S. preferred shows a gain of a quarter of a point, while Firestone common and preferred and Goodyear preferred remained the same with no change.

Of the car stocks General Motors common is 2½ points lower and the preferred also 2 points lower than last week. Reo Motor Truck stock rose 1½ points, while that of the Reo car company rose 3¼. Studebaker and White made a rise of 2 points. The rest of the securities made no, or very little, change.

The Detroit issues were steady with a few gains. Continental Motors common showed a gain of 20 points in sympathy with the Wall Street prices. Its preferred remained the same as last week. The rest of the changes ranged in gains from ¾ to 2¼ points. In the inactive stocks the only change that occurred was that of W. K. Pruden company with a gain of 75 points. The rest of the stocks remained dull with very little bidding going on.

France Orders Machinery Declared

Lathes, Presses, Hammers, Etc., Must Be Brought to Authorities' Attention

PARIS, July 24—A law just passed by the Chamber of Deputies declares that all metal-working lathes, hydraulic and other types of presses, and steam hammers must be declared to the military authorities. A period of ten days is allowed for making the declaration, which is binding on all owners, hirers, or in cases where the owner is absent on caretakers and landlords. The penalty for failing to declare is a fine of $10 to $200, and $10 to $400 for a false declaration.

Affects Automobile Industry

This new law particularly affects the automobile industry of Paris and surrounding district. There are around Paris hundreds of small shops doing work for the big automobile factories or building a small number of automobiles. Many of these shops are well equipped and undertake really high class work. As an instance, practically the whole of the machining of the parts for the Peugeot racing cars is done in the small outside shops and only assembled in the Peugeot racing department. The parts for Panhard motors for racing motorboats are machined outside; much of the special and experimental work for Delaunay-Belleville and Hispano-Suiza, to mention only two high-class firms, is undertaken by the small machine shops. With the large amount of experimental work always in progress in the French automobile industry, this system has become very extensive and has been found to give good results, for it does not disturb the normal output of the factory.

As the tendency of the war department is to attach themselves to the big firms, it is felt that sufficient use is not being made of the small shops. There are also cases where owners of machine shops have been called up for military service, causing their establishments to be closed and the machines to stand idle. The object of the law is to discover exactly what number of lathes, presses and steam hammers is standing idle and to put this machinery into use as early as possible. As it is difficult for a big corporation like the war department to deal with a multitude of small shops possessing two or three lathes each, there will be formed a series of co-operative societies, each under the control of an experienced manager. Where necessary, machinery will be removed from the shops in which it is now inactive and installed in a co-operative workshop. It is considered by the ammunition section of the war department that this system of industrial organization is almost as important as the creation of new shops equipped with new machinery brought from America.

The scheme has already been tested with satisfactory results among the small metal working firms attached to the automobile body building industry. These firms, which specialized in fenders, sheet iron work for automobile bodies, forgings for carrying fenders, windscreens, lamps and searchlights, were individually unable to do any effective work for the army, or to get material for executing private orders. In most cases, too, the owners were unacquainted with the routine necessary to get into touch with the department of the war office responsible for giving out orders. By forming them into co-operative groups, each one under the control of a competent business manager, they have been able to do very valuable work in the production of army field kitchens, mountings for anti-aircraft guns, army wagons, and different kinds of military equipment.

There is little or no change in the French automobile factories, which continue to work at high pressure on army orders: shells, guns, darts, bombs, and special types of automobiles for military purposes. Practically no cars are being produced for the French private trade.

A batch of 500 Jeffery ¾-ton trucks has been received in the French depots. These have come in chassis form, equipped with twin pneumatic tires at the rear. Bodies are to be built and fitted in the French bodymaking shops.

$216,027 for United States Metal Products Co. Assets in Sale

NEW YORK CITY, Aug. 2—The property and assets of the United States Metal Products Co., this city were sold at auction yesterday under the direction of John J. Townsend, referee in bankruptcy. There were forty-seven parcels in the sale and the total amount realized was $216,027. The creditors' committee bid $204,000 for most of the parcels and the rest went to outsiders for $12,027.

Among the parcels sold were the right, title and interest in the real estate and buildings at College Point, $40,000; patents, trademarks and welding contracts $10,000; recorders and motor trucks, $2,600; office equipment, $2,000. A petition in bankruptcy was filed against the company Nov. 13, 1914, and liabilities were $1,008,550.

—

Christensen for Navy Board?

MILWAUKEE, WIS., Aug. 2—Nels A. Christensen, president of the Christensen Engineering Co., and one of the foremost inventors of compressed air appliances in America, may be appointed a member of the new United States naval advisory board.

Pa. Horn Trap Is Hard Hit

Court Orders Verdict of Not Guilty for Harrisburg Club Secretary in Test Case

HARRISBURG, PA., Aug. 2—The horn trap in Pennsylvania was given a hard blow by a decision of Judge Johnson in the Dauphin county court at Harrisburg last week when a verdict of guilty was set aside and a verdict of not guilty ordered by the Court.

Secretary J. Clyde Myton, of the Motor Club of Harrisburg offered himself in the case against a constable and justice of the peace at Middletown, Pa. where a horn trap was maintained during the summer for several years. Each Sunday hundreds of motorists would be caught and notified to pay a fine or costs and the constables and justice made a big "killing." The case was not fought in the court, Mr. Myton pleading guilty but then the case was argued on the grounds that the constables had no jurisdiction to erect the signs and make arrests without the sanction and action of the township authorities.

The victory for the Motor Club shows that "horn traps" cannot be maintained unless signs are regularly authorized by borough or township official boards. Action will likely be taken against the constables and the justice of the peace to recover all money paid to them in the past and it is possible that other more serious charges will be preferred.

—

Ban Horns Near Churches

RED BANK, N. J., Aug. 3—Automobilists operating their horns within 500 ft. of any of the local churches during Sunday morning service will be arrested.

—

Edenburn A. A. A. Mich. Representative

DETROIT, MICH., Aug. 3—W. D. Edenburn has been appointed Michigan representative of the contest board of the A. A. A.

—

License Revoked for Intoxication

HARRISBURG, PA., July 30—State Highway Commissioner Cunningham has revoked the automobile license of Grover Zeller of Warren on information from District Attorney Frank J. Lyon that Zeller had been operating an automobile while intoxicated. Zeller was notified to appear for a hearing but failed to do so.

—

Wisconsin May Order Dimmers

MILWAUKEE, WIS., Aug. 2—It is likely that a law requiring every motor car to be equipped with a device for dimming the headlights will be passed by

the Wisconsin Legislature, which is still in session. A bill of this kind was killed in the State Senate, but reconsidered and is now slated for passage. The bill provides that no light shall be used which dazzles the eye, and each car must have a device whereby the light can be dimmed reasonably when within 250 feet of an approaching vehicle. The bill also has a provision that it shall be unlawful to drive a car at such speed that it cannot be stopped within the distance ahead that the driver can see an object the size of a person.

—

To Change Drivers' License Requirements in Massachusetts

BOSTON, MASS., Aug. 1—As a result of criticism by Judge Bryan and coupled with several serious accidents the Massachusetts Highway Commission plans to change the system of granting motor licenses to private owners in the future. Judge Bryan, in dealing with a recent case before him, said that he had issued a license to drive any kind of a motor car when, as a matter of fact, the only thing he knew anything about was an electric. He said the system was all wrong. So the commission took the matter up, and it will put into force a ruling that an owner must specify what kind of a machine he wants to drive and will be limited solely to that type.

—

Jitneys Stopped in Richmond

RICHMOND, VA., July 30—The jitney ordinance requiring a bond for each car operated in Richmond has driven all the jitney buses from the streets except one, which is testing the validity of the ordinance in the courts. As a result of the suppression of jitney traffic the street cars are packed and many persons were late getting to work.

—

1000 Arrests in Pittsburgh

PITTSBURGH, PA., July 30—At least 1000 alleged violators of the traffic and speed laws of the city were served with summons as a result of a crusade instituted by Mayor Armstrong against speed-mad drivers.

—

Speed Trap in Orange County

WALDEN, N. Y., July 30—When touring through Orange County beware of the speed trap at Walden. The police are arresting on first offense, giving no warning. The speed limit is 15 m.p.h.

—

Disco Gets Two Contracts

DETROIT, MICH., July 29—The Disco Electric Starter Co. has recently closed contracts with the Bimel Buggy Co., Sidney, Ohio, and the Canadian Regal Motor Co., Berlin, Ont., whereby the cars built by these concerns will have the Disco starter equipment on their 1916 models.

New Georgia Law Proposed

Bill Introduced Providing for $4 to $10 Fees on Hp. Basis—Dealers $30

SAVANNAH, GA., July 30—Representative Jones, Coweta County, introduced in the House a bill designed to remedy the defects of the present motor vehicle tax law as emphasized particularly in the recent decision of Judge Charlton in Chatham Superior Court. The bill was drawn following a conference with Secretary of State Cook and Attorney-General Clifford Walker. Its substantial provisions are that each motorcycle shall pay a license fee of $2, automobiles up to 25 hp., $4; from 25 to 40 hp. $7; over 40 hp. $10. Electrics are $5 when used as pleasure vehicles. Commercial vehicles are taxed $10 and automobile and truck dealers $30. From each fee $1 is to be retained as an adminstration fund, and the balance is to be paid into the State treasury as a public road fund which the Legislature may distribute either through a State highway commission or in such other way as it deems proper. The law provided for duplicate numbers to dealers on payment of $2; replacing of lost number for 50 cents and transfer of number to new owners for $1.

It is believed it will be satisfactory to the automobile owners of the State and comply with the defects in the present law as pointed out by Judge Charlton. Estimating upon the basis of the number of automobiles owned in Georgia, as shown by the records of Secretary of State, the adminstration fund would amount to some $30,000. The general road fund would amount to approximately $150,000.

The law will give the Secretary of State the power to appoint inspectors, whose duty it will be to see that the law is enforced.

The feature of the present law which provides for a distribution of the fund by counties according to rural delivery mileage is retained. This will probably have to be changed to conform to the opinion of Judge Charlton.

—

Wagenhals Co. Bankrupt

DETROIT, MICH., July 30—The Wagenhals Motor Co. which has been making gasoline and electric three-wheel delivery cars, many of which are being used by the Detroit postoffice department, was declared bankrupt a few days ago in the U. S. district court. The liabilities, according to the concern's schedule, total $13,673.91 of which $3,858.45 is recorded as a priority claim as salary due to General Manager W. G. Wagenhals. The concern claims assets having a total value of $15,100, consisting principally of machinery, tools, equipment, stock and also U. S. letter patent No. 1,030,357.

The first meeting of the creditors is to be held in the bankruptcy court Aug. 12.

—

To Reorganize Jagers Manufacturing Co.

RACINE, WIS., July 24—The George W. Jagers Mfg. Co., Racine, Wis., gasoline engines, is about to be reorganized by a committee of creditors. The company ceased operations about three weeks ago because of lack of working capital. It holds a large contract to furnish motors for the Argo Motor Co., Jackson, Mich., and under the reorganization plan new capital will be introduced to fulfill a large number of orders now awaiting production. The creditors' committee has requested all claimants to accept a part-cash, part-note and part-stock settlement of accounts payable and it is expected that with the business in sight there will be no objection to the plan by any of them.

—

Hawkeye Tire Co. Formed

DES MOINES, IOWA, Aug. 3—The Hawkeye Tire Co., has been organized here and will build a factory as soon as arrangements can be completed. The company was formed by I. V. McLean who will be its first president. On the board of directors are E. Raffensperger, O. B. Hextell, T. H. Dexter and J. T. Christie. The company will place $200,000 of preferred and $300,000 of common stock on the market. A full line of tires will be manufactured.

—

Standard Tire Co. Organized

KEOKUK, IOWA, Aug. 2—The executive council has issued an order authorizing the Standard Tire Co. of Keokuk to issue its stock. This is a new corporation organized here for the manufacture of automobile tires. It expects to operate upon a fairly large scale as soon as its plant is ready.

—

Studebaker to Buy Elkhart Plant

SOUTH BEND, IND., July 30—The Conn Musical Instrument factory at Elkhart, Ind., is to be taken over by the Studebakers of South Bend. Colonel G. M. Studebaker and Clement Studebaker, it is stated, have arranged to purchase the property for $800,000.

—

Ford Plant for Oklahoma City

OKLAHOMA CITY, OKLA., July 30—An assembling plant that will employ between 300 and 500 men is to be built in this city by the Ford Motor Co. within the next six months. The plant will be situated on the block of ground west of the court house.

Oldfield Breaks Four Records

Cuts Times for 1, 3, 4 and 5 Miles in Exhibition Trials at Cleveland

CLEVELAND, OHIO, Aug. 2—Four world's records for a dirt track are reported broken by Barney Oldfield in an exhibition trial for records held here yesterday under the sanction of the American Automobile Assn. The new times are: 1 mile 0:46¼; 3 miles, 2:25 2/5; 4 miles 3:13 3/5 and 5 miles 4:03 1/5. The former mile mark held by Oldfield was 0:46 2/5. Disbrow held the other records in 2:27.81; 3:17.2 and 4:06.58.

The rules of the American Automobile Assn. provide that all records established for distances under 5 miles shall be timed by an automatic timing device.

—

Twin City Speedway Progresses

TWIN CITY, MINN., July 31—The Twin City Motor Speedway work progresses rapidly. Nearly 1 mile of concrete is completed, which is one-half the length of the track. One grandstand is completed, there are to be six and two bleachers. The grading of the track and inclosure is completed and the subways are being built. Two more entries have been made for the 500-mile Derby on Sept. 4, those of Resta and DePalma. The street railway company will construct lines to the grounds if the association will get right-of-way across Fort Snelling reservation from the government and grade it. The speedway location adjoins Fort Snelling, which is between Minneapolis and St. Paul.

Three Peugeot cars have been entered for the World's Derby, Sept. 4, on the Twin City Motor Speedway. They will be driven by Ralph Mulford, Johnny Aitken and Howard Wilcox. The Mulford car was entered by Luther Brown of Orange, Tex., and the other two by the Speedway Association of America. Seat sales for the race are going along rapidly and work is progressing, so that it will be completed by Aug. 15 for the preliminaries.

—

Los Angeles Show in October

LOS ANGELES, CAL., July 25—California's greatest automobile show is to be held in Los Angeles the latter part of October. The event is to be known as the Broadway Automobile and Flower Show and is to be held under the auspices of the automobile dealers of Los Angeles.

Councilman J. S. Conwell has been named as manager of the show, and the committee appointed from the motor car dealers includes Ralph C. Hamlin, P. H. Greer and Earle C. Anthony.

In the entire building, which is located in the very center of the business district of Los Angeles, there are 60,000 ft. of floor space. A large share of this has already been sold.

—

Parade to Sheepshead Practice

NEW YORK CITY, Aug. 2—Practice for the forthcoming race on the Sheepshead Bay Speedway will be inaugurated by a parade Sept. 18, which will be promoted by the Motor Club of New York, and in which it is expected many New York and Brooklyn dealers will participate. One section of the parade will be for decorated cars for which prizes will be offered. There will also be a prize for the dealer having the greatest number of owners' cars in line. Participants in the parade will be permitted to view the practice free.

—

Kokomo Man Wins Saxon Fuel Economy Prize

DETROIT, MICH., July 29—The jury of local newspaper representatives has awarded first prize in the Saxon Motor Co. economy run to C. E. Seaward, Jr., Kokomo, Ind., who covered 327.2 miles, averaging 26.2 miles to the gallon of gasoline and consuming 1 quart of oil.

J. S. Hoffman, Sharon, Pa., averaged 26 2/3 miles to the gallon of gasoline, or better than the winner's record, but he covered a shorter course and had better roads. William P. Knipper, Rochester, N. Y., made a non-stop run of 462 miles, it is said, averaging 24 miles to the gallon of gasoline. Another long run was made by Miss Edna Riesenthal, Milwaukee, Wis., who, it is said, drove 480 miles at an average of 24 miles to the gallon.

A total distance of 26,377 miles was covered by the 105 contestants, who averaged 252 miles each. The average consumption was 1 gal. of gasoline per 21 miles and 1 quart of oil for a distance of 152 miles.

—

Portland Plans October Show

PORTLAND, ME., Aug. 1— Maine will probably have the honor of opening the 1916 show season in New England if plans discussed by the Portland dealers go through. They met a few days ago and began arrangements to have a motor show in the Exposition building on Park Avenue in October.

—

Lawrence Takes Velie in Chicago

CHICAGO, ILL., Aug. 4—The Velie agency in Chicago has been taken over by J. V. Lawrence who has opened salesrooms at 2530 Michigan Avenue. Mr. Lawrence has for years been a partner with H. Paulman & Co., Pierce-Arrow agent, and will retain his connection with this organization, dividing his time between the two concerns.

Eight Qualify for Des Moines

DePalma Nearly Breaks Record for 5 Miles—More Elimination Trials

DES MOINES, IOWA, Aug. 2—Ralph DePalma and his "Stuttering Stutz" came within 5.6 sec. of the world's record for 5 miles and eight cars and drivers qualified for the Des Moines Speedway races on Aug. 7 at the elimination trials held Saturday. Two cars and drivers failing to qualify were Barndollar with a Clergy Special and Lombardi with an O'Connell Special. Fred J. Wagner was official starter and timer.

97 1-3 M.P.H. by DePalma

DePalma lengthened his elimination mile to a 5-mile exhibition. His first lap, the elimination mile, was in 36.98 sec. or at the rate of 97 1/3 m.p.h. and was the fastest mile of the day, in the eliminations. In the last four laps of his 5-mile exhibition he made three laps in 36.9 each and his time for the 5 miles was 3 min., 4.65 sec., or at the rate of 97.5 m.p.h. Bob Burman made an exhibition 5 miles in 3 min. 8.33 sec. or 95.4 m.p.h. Later he stretched his elimination mile, made in 37 sec., to a 5-mile exhibition which was halted when he blew his outer rear tire in the last lap. He kept the car on the track.

Eddie O'Donnell of the Duesenberg team qualified in two cars, one for himself and one for Ralph Mulford who had not arrived and who will drive one of the Duesenbergs in the big race. Elimination miles were as follows:

Driver	Car	Seconds	M.P.H.
DePalma	Stutz	36.98	97.33
Burman	Peugeot	37.00	97.00
Cooper	Sebring	38.60	94.00
Alley	Ogren	40.20	89.20
Brown	DuChesnau	50.00	77.50
Barndollar	Clergy Spl.	50.00	77.50
Strunk	White Spl.	40.40	89.00
Chandler	Duesenberg	42.33	84.25
O'Donnell	Duesenberg	42.60	84.00

O'Donnell also qualified a Duesenberg car for Mulford. Starter Wagner fixed a minimum speed of 80 m.p.h. for one lap as necessary to qualify for the race. Those which failed to qualify Saturday have two more trials to make good. A. F. Scott, pilot of an Anderson Special, deferred his tryout because of damage to his car.

The ranking of the drivers who qualified Saturday is as follows: DePalma, Burman, Mulford (by O'Donnell), Cooper, Chandler, Alley, Strunk, O'Donnell.

Additional elimination trials will be held on Tuesday and Wednesday afternoons of this week. Indications are that ten cars will qualify for the main event which will be for a distance of 300 miles and for prizes aggregating $10,000.

Thrills at Rose City Speedway

Parsons, Elliott and Lentz Stars in 2-Day Race Meet —Small Attendance

PORTLAND, ORE., July 28—In the Northwest automobile events held here July 24 and 25 the winners were James Parsons, Frank Elliott and Ray Lentz before a crowd of 1500 who gathered at the Rose City Speedway.

The fastest mile of the afternoon, 53 sec. flat was credited to Jim Parsons when each of the drivers were sent away separately with flying starts, but the best time in racing fell to the honor of Frank Elliott, in his Gordon Special, who made the twenty-first and twenty-second laps of the 25 mile event in 54 3/5 sec. each.

In the 25 mile event it was nip and tuck between Parsons and Elliott for most of the distance; Elliott leading for the first 10 miles when Parsons was a nose ahead and it looked as if he was a possible winner, but tire trouble slowed him up and the white Gordon won by inches. Harry Stratton's Mercer, which was piloted by Sig. Tafil, lagged woefully in the rear. The time for the event was 23 min. 23 1/5 sec.

The record time for Portland was established last year when Percy Barnes with the eight-cylinder Romano made the quarter century in 22 min. 7½ sec.

Some of the real thrills of the day resulted when the Gordon Special, Parsons Special and Schneider and Stutz specials were turned loose on the 10-mile event. After grabbing the pole at the start and keeping it for seven laps Elliott was bettered by Parsons, who had to make four consecutive laps in less than 56 sec. to turn the trick. The total time for the event including the start was 9 min. and 25 sec., and the fastest lap was the final one done in 55 1/5 sec. Gus Duray got the upper hand with his Schneider Special, beating Oral Palmer to third place, the latter driving the Stutz piloted by Earl Cooper in 1913.

In the 15-mile event Lentz with Barsby's Velie won easily in 15 min. and 8 sec. Fred Forbes finished second in his Buick.

After winning the first two races in the first day's events in very exciting finishes, Jim Parsons was forced to withdraw from the 50-mile contest, and left Frank Elliott driving his Gordon Special complete master of the situation. Elliott ran away from the balance of the field and finished the 50 miles in 50 min. 27 4/5 sec.

This time would have been very much faster had it not been for the fact that a drove of horses were allowed by the groundkeeper to get out on the track. Harry D. Stratton driving a Mercer special finished second, and Gus Duray, in Schneider special, third. Fred Forbes, driving his Buick Special, was a close contender for second honors for twenty-four laps, when he was forced to the pits with valve trouble.

Parsons took the special match race of 3 miles from Ernest Schneider after being forced to drive the fastest three laps made during the meet. Parsons finished in 2 min. 51 3/5 sec.

The Velie special driven by Ray Lentz was the star performer in the second flight of cars, winning both the 5-mile and 10-mile race, but was forced out of the big race in the sixth lap on account of engine trouble.

—

Properly-Designed Muffler Can Increase Power Output

LONDON, ENGLAND, July 30—Increasing the horsepower of an engine by adding a properly designed muffler is proven in a recent issue of *The Autocar* in which experiments are described by one, C. J. Booth, who with a standard four-cylinder engine, 100 by 140 mm. (3.93 by 5.51 in.), was able to show an increase in horsepower by fitting satisfactory mufflers, as compared with the power generated when neither muffler nor exhaust manifold was fitted. With the engine operating at 1750 r.p.m., the horsepower obtained without a muffler or exhaust pipe was 41.75; when long straight exhaust pipes which ran with easy sweeps into one exhaust pipe were added, the power was raised to 44.5 hp.; when the standard muffler used on the car with the standard exhaust pipes was fitted the horsepower was 36.75, or less than without exhaust pipes or muffler; and finally when this standard muffler was taken and modified the horsepower output was increased to 42, which was in advance of that obtained without muffler of exhaust manifold.

At lower crankshaft speeds similar results were obtained, although not so prominent. The accompanying table shows the results at different crankshaft speeds. The tests were made with an ordinary electrical dynamometer. The type of muffler used was a simple one, having an expansion chamber divided by three baffle plates. By removing two of the baffle plates, it was possible to obtain increased power as shown in test 4 in the tabulation.

Power Tests With and Without Muffler at Different Speeds

Engine r.p.m.	Test No. 1 with Standard Silencer Hp.	Test No. 2 without Silencer or Exhaust Pipe Hp.	Test No. 3 with Exhaust Pipe Only Hp.	Test No. 4 with Standard Silencer Modified Hp.
500	14	14¼	14¼	14¼
750	22½	23½	23½	23½
1000	28½	30¼	30½	30¾
1250	33¼	36½	37¼	36¾
1500	36	40½	42	41
1750	36¾	41¾	44½	42

Europe Developing 8's and 12's

To Appear on Market After the War—Aviation Practice of Value

PARIS, July 26—If the war had not intervened, it is certain that the 1915 European shows would have marked the appearance of twelve-cylinder motors. In England the Sunbeam company has produced a twelve for aviation purposes, and is already supplying this type of motor in big quantities to the British and French flying corps. It is understood that Sunbeam has made all arrangements for producing a car with a twelve-cylinder motor, but this cannot be offered to the public, for the entire output of the factory has been requisitioned for military purposes. It is declared that the car is fitted with two speeds only, the low gear being for starting away and emergency service, for the motor will be capable of doing 99 per cent of its work through direct drive.

Renault is also credited with the production of a twelve-cylinder motor which will first be used on aeroplanes. Up to the present Renault has devoted all his attention to the building of eight-cylinder V-type air-cooled aviation motors, in which field he has been very successful. The demand is for bigger and more powerfully armed aeroplanes, necessitating the use of motors from 200 to 300 hp. In very many cases these new flying machines have been fitted with two purely aeroplane type motors of 120 to 150 hp. each, the type of motor most commonly used being those with seven or nine fixed cylinders around a circular crankcase. The value of the big, heavily armored aeroplane having been proved, the call now is for very big light-weight, water-cooled twelve- and eight-cylinder motors. It is not known whether Renault has any intention applying his twelve-cylinder motor to cars, but there is no doubt that the experience gained in the air will be useful on the road.

What Makers Are Doing

Engineer Henry, who was responsible for the design of all the Peugeot sixteen-valve racing motors, has presented to the army his first series of eight-cylinder thirty-two-valve aviation motors of the

same general design as the four-cylinder motors used in European and American races the last two or three years. Henry has produced these motors in conjunction with Despujols and Barriquand, having severed his connection with the Peugeot company. Lorraine Dietrich is producing a six-cylinder aviation motor of the same general design as the Mercedes engine. Fiat has built a large number of motors of this type. Clerget, a leading French aeroplane motor specialist, has opened a big factory in Italy for supplying aeroplane motors to the Italian army. Canton-Unné, another aeroplane motor specialist, is now building in Russia, in addition to running a French factory which has been tripled since the outbreak of war.

Not on American Scale

Several French car factories have studied the eight-cylinder situation very closely and have practically decided to put an eight on the market as soon as the war is over. At the present time it is impossible to do more than the experimental work. Although the eight and the twelve are attracting interest, it is certain that they will not be built in Europe in anything like the same proportion as in America. The point is that aviation developments are tending toward the eight and twelve fixed cylinder motor, in preference to the seven and fourteen rotary, and this tendency will have its influence on the automobile situation.

—

Many Sales on Ohio Tour

COLUMBUS, OHIO, July 31—A booster automobile tour under the auspices of the *Ohio State Journal* was pulled off last week with excellent results by a general committee representing car agents and dealers in accessories. Stops were made at Lancaster, Circleville, Washington Court House, Chillicothe, Springfield, South Charleston, London, Plain City, Marysville, Delaware, Marion, Mout Gilead, Fredericktown, Mount Vernon, Utica and Newark.

From the business standpoint all of the agents who participated believed it was a good thing. Many prospects were secured, and it is planned to run such a tour each year. About a score of cars were represented in the tour.

—

Carolina's Wholesale Supply House

CHARLOTTE, N. C.—The Carolinas Automobile Supply House, Inc., has been formed to handle automobile accessories in a wholesale way throughout the two Carolinas. The company will make a specialty of parts and accessories for Ford cars. Joseph G. Fitzsimons is president and general manager, William A. Graham, vice-president, and Wade A. Montgomery, secretary and treasurer.

Dealer to Pay Car Freight

Los Angeles Distributor Will Sell for Cash Only—No Used Cars

LOS ANGELES, CAL., July 27—Lynn C. Buxton, distributor of the Moon and Lexington lines in southern California, has created a sensation throughout the automobile industry of this section by announcing that he will pay the freight on all cars sold in his territory. Buxton further announced that in the future he will sell for cash only, making no time deals and taking in no used cars on new models.

In the past the freight has always been added to the purchase price of cars sold in southern California and on the large machines this has meant a great increase in first cost. Selling for cash, the local dealer is selling all cars at the factory price, something unheard of before in southern California.

The majority of the Los Angeles dealers operate used car departments, but Buxton intends to eliminate the used car from his business through his cash sales system.

—

Packard Takes Over Boston Service Station and Salesrooms

BOSTON, MASS., Aug. 1—Papers were filed in the registry of deeds at Boston this morning transferring from Alvan T. Fuller to the Packard Motor Car Co. of Detroit, Mich. the big service station and salesrooms of the Boston Packard branch. The stamps on the papers indicated that the sale represented $285,000. That is about the value of the building.

Mr. Fuller could not be seen all day, and at the office of his company when it was stated that the inference from the sale would be that the Packard Motor Car Co. of Detroit had taken the business over as a branch some of the subordinates stated that such was not the case. But they would go no further in saying anything.

In taking over the Boston business the Packard company would also have to take over the Providence and Portland business controlled by Mr. Fuller to make the matter complete. So the entire transaction would represent at least a deal involving $1,000,000.

—

Capt. Ryus Heads California Oldsmobile Sales Forces

LOS ANGELES, CAL., July 26—Capt. Harmon D. Ryus, one of the oldest men in the automobile industry of California in point of service, who for the past five years has been manager of the Oldsmobile factory branch at Los Ang is now president and general man of the Oldsmobile Co. of California.

With F. G. Seager of New York Pasadena, Cal., Captain Ryus purch the Los Angeles and San Francisco tory branches and the Pacific Co agency for the Oldsmobile. This age territory includes California, Oreg Washington, Arizona, Nevada, the waiian Islands and western half Idaho.

The San Francisco branch will be charge of Captain Ryus, and the m offices of the Oldsmobile Co. of Cali nia will be located in San Franci The branch and agency connections now being completed.

With the exception of Larson, N York distributor, the company of wh Ryus is now head is the largest O mobile distributing organization.

—

Limousine Top Co. Formed

KALAMAZOO, MICH., July 31— Limousine Top Co. has been formed to manufacture demountable tops in for manufacturers of automobiles, ers and distributors of certain mak cars and for individual car owners. company is capitalized at $30,000, a composed of James D. Bobb, Loren Bennett, David H. Harris, Frank H. ham, W. D. Milham, Burton E. Ba W. E. Kidder, Glenn S. Allen, Har Vander Horst, George J. Putt, Jam Dewing, Dr. W. E. Upjohn, Frank ner and Vernon T. Barker. The com has already secured a number of tracts and expects to increase its fo mechanics to 100 or 150 in the future. In addition to making dem able tops the concern plans the m facture of bodies and a line of sories. Factory quarters are in th Michigan Buggy Building.

—

Don Lee Gets Oakland

SAN FRANCISCO, CAL., July 29- Lee, who long has represented the lac in northern California, has been distributor for the same territor the Oakland. The branch which th land company has maintained i Francisco will be discontinued. Roberts, Pacific Coast sales manag the Oakland company who w charge of the branch, will maint office at the Don Lee headquarters

—

$200 Fee for Filling Station

DENVER, COL., July 29—A license fee of $200 for motor car stations is provided by an ord just passed by the city council. new law is interpreted as applyin to the regular filling stations th exclusively in gasoline and oil, a to garages. Denver now has six these filling stations, which ha

been installed during the last two years. Some of the filling station proprietors claim the law is unjust and that it involves class legislation. Little hope is expressed of getting the measure set aside, however. The new ordinance is regarded generally as likely to prove a benefit to garages.

—

To Distribute Dolly Madison

INDIANAPOLIS, IND., Aug. 2—The Darmie Motor Sales Co. has been formed here to take over the distribution of the Dolly Madison car manufactured by the Madison Motors Co., Anderson, Ind.

—

Retlaw Sales Co. Formed

DETROIT, MICH., Aug. 2—The Retlaw Sales Co. has been organized with offices in the Dime Savings Bank Building, to act as distributor for the Retlaw Mfg. Co. manufacturer of gasoline and oil gages and special gasoline gages for Ford cars. Frank J. Burrows, who was purchasing agent for the Briggs Detroiter Co. and F. W. Marschner are interested in the sales company.

—

More Territory for Haynes Distributor

ST. LOUIS, MO., July 31—All of Arkansas and part of Kentucky have been added to the territory in which the Newell Motor Car Co. of St. Louis represents the Haynes factory. The local company already has the agency for Missouri and southern Illinois.

President James E. Newell says he will establish a branch at Little Rock, Ark., soon and will put several additional salesmen on the road.

—

To Distribute Reo in Nevada

RENO, NEV., July 31—The Durham Sales Co. was organized July 10 with a capital of $25,000 with the following officers. C. W. Mapes, president, J. C. Durham, vice-president and general manager, T. R. Gibson, secretary, Washoe County Bank, treasurer. The Durham Sales Co., Inc., is direct factory distributors for Reo cars and trucks in Nevada, Mono, Alpine, Plumas, Sierra, Nevada, Lassen and Modoc Counties in California and Klamath and Lake Counties in Oregon. A complete line of accessories and parts will be carried.

—

Pullman New York Agency Discontinued

NEW YORK CITY, Aug. 3—The Kent Motors Corp. has been formed to take over the Pullman Sales Co., 1704 Broadway, the Pullman agency having been discontinued. The Kent concern will handle the Abbott and Marion and will continue Pullman service work until other arrangements are made.

Fourteen Methods of Examining Motor Fuels

(*Continued from page* 249)

with the lower boiling point at 80 degrees lacks the volatile components which make the motor responsive to acceleration. The conception of an ideal motor gasoline should be changed in the way of modifying the demand for narrow boiling limits by insisting on light components, which means with boiling points 40 and 100 or 110 instead of 80 and 120 degrees.

When three gasolines of 80 and 90, 90 and 100 and 100 and 110 degree limits are mixed, there is obtained a fluid containing about 25 per cent of components which do not boil above 100 degrees and with a specific gravity of .740. Its period of evaporation is about 3 hours and its price 1.50 mark per kilogram. Despite its narrow boiling limits it is not an ideal motor gasoline.

In the proposed classification, the boiling limits for class A are to be given as 40 and 125 degrees with not more than 10 per cent distilling above 100 degrees C.

For class B the limits may be 45 and 140, with at most 30 to 50 per cent above the 100-degree boiling point, and for class C 65 degrees lower limit, 150 to 170 degrees upper limit, with not more than 75 to 80 per cent above the 100-degree limit.

13. Refractometer Test

Petroleum is optically active. Oils of resin, fats, turpentine, gasolines and benzols can be distinguished from each other by spectral observation with a refractometer. The use of this means for testing motor fuels has been theoretically considered before, but was never applied in practice.

In the present series of examinations it was found that with the large Zeiss-Pulfriech refractometer could be used successfully for determining the refractometer degree. The lamp employed was one indexed Ia ND 1,62100, and the readings taken of the refractometer degree were recorded after converting them into the corresponding angles of refraction, as the differences in this manner become more prominent.

The refractometer degree at a temperature of 20 degrees is to be determined, in each instance, by leaving the fluid to be tested for several hours in the room where the test is to be made, so that both the instrument and the research material will acquire the temperature mentioned, which is maintained in the room. It is recommendable to cover the container of the test fluid with a glass lid during the process of examination to avoid evaporation which, in the case of light gasolines, causes blurring of the boundary line and leads to inaccurate reading of the refractometer degree.

This degree varies for motor gasolines from 50 to 59 and is highest for the most perfect fuel. Class A should have a refractometer degree not lower than 54, class B not below 53 and class C at least 50.

Benzols have a much lower refractometer degree, varying from 37 to 38. But a crude lighting benzol cannot be distinguished from a pure motor benzol by means of the refraction of light, while different gasolines can be classified by this method, without rendering fractional distillation superfluous, however. The refractometer degrees of toluols are slightly higher than those of benzols, and those of xylols still higher. A benzol with strong aromatic components will therefore register a little higher by this measure than motor benzol.

Motor alcohol shows a refractometer degree of 58 to 59, and the test can therefore be used to advantage for proving an admixture of alcohol to benzol.

As pentane shows the highest (59° 30) and heptane (53° 49) and olefines low refractometer degrees, good and light gasolines contain more pentanes and other grades more hexane and heptane.

Among the fractional components of gasolines those boiling above 100 degrees C. show the lowest refractometer degree and those boiling below 100 degrees the highest, while that of the gasoline as each lies in the middle. With benzols the opposite is the case, the heavier components having the highest refractometer degree. [Dr. Dieterich here furnishes a list of the refractometer degrees for a scale of fuel mixtures produced synthetically by mixing normal gasoline with pure benzol in different proportions; also for the isolated fractional components.]

It is noted that the refractometer degree for a mixture of gasoline and benzol in equal parts drops to 48, and the test can therefore be considered of practical utility, being in itself simple and quickly made.

Test No. 14 relates to prices, which of course should be in harmony with the properties revealed by the other 13 tests and with the classified specifications listed in the previous instalment.

Foster Gear Plant Rushed—J. B. Foster, secretary-treasurer of the Foster Gear Co., Columbus, Ohio, says orders for steering gears are being received so fast that it is a difficult matter to keep up deliveries. The company now has about sixty-five men on its payrolls and plans are being made for an addition to the plant. An order for 18,000 sets of steering gears has been reecived recently and there are orders for about 25,000 more in prospect.

Hess-Pontiac Works Busy—The Hess-Pontiac Spring & Axle Works, Pontiac, Mich., are taking on as many men as they are able to get in anticipation of the busiest year they ever had. This concern's output is largely taken by the Ford Motor Co. For quite a while efforts have been made to get skilled labor and it is said that the factory managers are paying the moving expenses of families coming from far distant localities.

Pierce-Arrow Storehouse—Erection is well under way in Buffalo, N. Y., of a new warehouse for the Pierce-Arrow Motor Car Co. The building will be four stories without basement, and measures 453 by 61½ ft. Construction is reinforced concrete with mushroom floors, the spans being 20½ ft. The lower floor, which is of wooden blocks on concrete base, is located directly on the ground. A covered platform alongside, at the height of the sills of railroad cars, is fitted for the receipt and shipping of motor truck parts, the transfer between the platform and building being by means of three short-lift elevators. The upper floors are finished with granolithic top. The building has steel sash with wire glass. Steam heating will be used—a departure from the blower system in use elsewhere in the plant.

Seek Skilled Labor—The Detroit Pressed Steel Co., Detroit, Mich., last week attempted to fill its urgent requirements for skilled labor by sending a representative to Milwaukee, where the newspapers were liberally patronized for "want ads." So many positions are open in Milwaukee, however, that the company met with little success. The free employment office operated in Milwaukee by the Wisconsin Industrial Commission is unable to fill all the calls for skilled help that are sent in by Milwaukee and southern Wisconsin manufacturers, particularly in the motor car trade. The Mitchell-Lewis Motor Co., Racine, Wis., sent a hurry call to the bureau last week for fifty machine hands, but was able to get only half that number. The Racine company at the same time left a standing order for all the experienced motor car factory help that could be procured, and men are being sent to Racine as rapidly as they present themselves. The situation is considered unprecedented, for not in many months has there been even a semblance of an urgent demand for skilled labor.

New Chevrolet Plant—Ground was broken recently on the new plant of the Chevrolet Motor Co., Detroit, Mich. This plant will be used for the manufacture of motors and will employ 1100 mech ics. The building, 616 by 150 ft., story, with 2⅛ acres of floor space, be ready for operation by Sept. 15.

With a view to being prepared further expansion, the company wi the last three weeks has acquired p erty on both sides of the Flint Rive the Fourth and Fifth wards sufficie care for all future development.

The new property acquired incl about a dozen residence buildings must be removed, some of them w the first new structure will be built west of the Mason Motor Co., one o Durant companies, which was acq by the Chevrolet company recently, while it will continue to be conduct a separate institution with a sep organization, its function will be to all of the motors for the Chevrolet p in Flint, New York City and Tarry With the new building the prod will be increased to 1000 motors a

The Mason plant is working nigh day shifts with a force varying fro to 750. With the completion of th building the day force will probab increased to about 1500.

Gray & Davis Employee's Out Some 2000 employees of Gray & Inc., Boston, Mass., together with families, attended the annual field Wakefield July 31. Field sports game, tug-of-war, water races, etc nished interesting events in the pr It required forty-seven trolley c transport the operatives from Bos the grounds.

The Week in  the Industry

Buckbee with Ahlberg—George A. Buckbee has been made manager of the Boston branch of the Ahlberg Bearing Co., Chicago.

O'Rourke Purchasing Agent—J. S. O'Rourke has been appointed purchasing agent of the Oakland Motor Car Co., Pontiac, Mich., succeeding H. R. Vinot, resigned.

Garage

New Fox Lake Garage—Albert Paulson has established a garage and repair shop at Fox Lake, Wis., occupying the Fox Lake Garage.

A $20,000 Garage—A large garage costing about $20,000 is being erected on Lisbon Avenue, near Thirty-first Street, Milwaukee, Wis., by Graf Bros.

Lakeside Garage Opened—C. H. Wilkenson has opened a garage and repair shop in Lakeside, Mich. His specialty is to take care of repairs on Ford and Overland cars.

$22,000 Garage Fire—Fire caused a $22,000 loss in Anniston, Ala., when the brick garage owned by Joseph Saks was destroyed together with automobiles valued at $10,000.

Fifty-Truck Garage—L. O. Stewart & Bros., coal, wood and ice merchants of Washington, D. C., are planning a garage to accommodate fifty trucks. The structure will have 20,000 sq. ft. floor space and its cost will be $10,000.

Enter Garage Field—W. D. Johnson, Lancaster, Wis., and R. J. Hoover, Sauk Prairie, Wis., have formed a partnership and will engage in the garage and repair business at Lancaster. The firm has plans for a $5,000 garage building 60 by 132 ft.

Recent Wisconsin Garage Happenings—W. W. Osborn has opened a garage and repair shop in the Stroebel warehouse building on Main Street, Neenah, Wis. Hunt & Machia, operating the Sawyer Garage at Sturgeon Bay, are now located in their new fireproof garage, erected on the site of the building destroyed by fire on Sept. 13, 1914. The Western Iron Stores Co., Milwaukee, one of the largest wholesale and retail dealers in mechanics' tools, machinists', mill and shop supplies, has moved to new and larger quarters at 145-147 West Water Street, one block south of Grand Avenue. The Main Auto Co., Appleton, has purchased the stock, equipment and business of the Griffin Auto Co., Appleton.

Motor Men in New Roles

Bertman Succeeds McManus—A. W. Bertman has succeeded E. E. McManus as advertising representative for the St. Louis, Mo., branch of the Firestone Tire & Rubber Co.

Kenney in St. Louis—F. C. Kenney, who has been managing the Memphis, Tenn., Studebaker branch, has returned to St. Louis, resuming his former position of assistant manager at that branch.

Hopkins Goes to Providence—E. C. Hopkins, formerly identified with the Boston branch of the Buick Co., has gone to Providence to become manager of the Buick agency in Rhode Island controlled by Charles F. Thatcher.

Gets National Tire—The Barnthouse-Hemmerly Auto Co. has secured the agency in Marion, Ohio, for the National tire.

Arnold Branches Out—The Arnold Auto Co., Wichita, Kan., will establish a branch house at Hutchinson. The concern handles the Chalmers.

Studebaker in Oklahoma City—A wholesale Studebaker branch has been opened in Oklahoma City under the management of Iver Schmidt.

Bimel Indiana Headquarters—The Bimel Buggy Co., Sidney, Ohio, maker of the Elco "30," has established State headquarters in Indianapolis, Ind. A. C. Nobes, president of the Sidney concern, is in charge.

Move to New Quarters—The salesrooms of the Paige Detroit and the Saxon in Boston, Mass., have been moved into a new building just finished at 595 Newbury Street. Both companies will have ample quarters for salesrooms and service stations.

Installs New Furnace—The Wisconsin Welding & Cutting Co., Milwaukee, Wis., is installing considerable new equipment, including a furnace costing $1,500. The shop is now equipped to weld aluminum, this department being in charge of Gustave Johnson, an expert in this line. C. H. Hansen is general manager.

Welding and Cutting Shop—A welding and cutting shop that makes a specialty of motor car work has been established at Green Bay, Wis., by Walter F. Gerald, formerly associated with the Universal Oxygen Co., Sheboygan, Wis. The new shop is known as the Badger Welding & Cutting Co., and is located at 127 South Barclay Street.

Ogg Detroit Electric Mgr.—Basil Ogg, former president of the Springfield Auto Sales Co., Springfield, Ill., has been appointed manager of the branch house to be established by the Anderson Electric Car Co. of Detroit, and which will open for business at 218-222 South Fourth Street, Springfield. Mr. Ogg will devote his entire time to this firm.

Dealer

Opens in Louisville—The Paige Motor Sales Co., which secured the Paige agency in the Louisville territory Aug. 1, has opened an office and salesroom at 725-729 South Fourth Street, Louisville, Ky., formerly occupied by the Kentucky Motor Car Co. Edward A. Briel is president and manager of the new concern.

Peck in New Quarters—The Peck Auto Sales Co., Studebaker distributor in the Grand Rapids (Mich,) territory, has completed and moved into its new service station repairshop. The building is concrete and brick construction. The present quarters of the company across the street will be devoted to sales and office purposes.

Shop and Service Station—The Hudson-Brace Motor Co., handling the Hudson in Kansas City, Mo., is building a shop and service station 50 by 112½ ft. on Oak Street, in the rear of their present salesrooms. The present quarters where the shop is now located will then be used for salesrooms, second-hand cars and cars in process of delivery.

Judd Takes Over Business—John L. Judd, who has been traveling representative for the E. A. Gilmore Co., Boston, Mass., New England distributor for the Lewis VI and the Allen cars, has taken over the business and he will continue it at the present salesrooms, 92 Massachusetts Avenue. Mr. Gilmore has retired from the business entirely and he may go to Worcester to handle the Dodge.

Opens in Kansas City—The Bush-Morgan Motor Co. opened for business Aug. 2 at 1526 Grand Avenue, Kansas City, Mo., as agents for the Paige car. They have a well-equipped repair shop and service station, handsome offices and commodious salesrooms. Mr. Roy R. Bush was formerly well known in the farm implement field when with the Kingman-Moore Co.; later he was with the Velie Co. at Moline. Mr. W. H. Morgan has been associated with Mr. Bush for many years.

Birmingham Co. Moves—The Turner Electric Supply Co., Birmingham, Ala., has moved to 2104 First Avenue.

Buys Supply Co.—The Austin Tire & Supply Co., with C. L. Pate manager, has purchased the business of the Aber-Schultz Auto Co. at Austin, Tex.

New Dallas Velvet Co.—D. L. Ormsby, distributor of Velvet shock absorbers for the State of Texas, has sold his State rights to the M. & S. Sales Co., Dallas, Tex.

New Los Angeles Garage—R. Starkweather has opened a general repair shop at 726 West Pico Street, Los Angeles, Cal., to be known as the Imperial Garage.

Packard Electric in Detroit—The Packard Electric Co., Warren, Ohio, has opened a branch office in the David Whitney Building, Detroit, Mich. W. L. Marsh is in charge.

Madison Opens in Louisville—The Madison Co., which recently acquired the agency for the Madison, has opened an office and salesroom at 206-210 East Broadway, Louisville, Ky.

New Garage for Shawano—The F. H. Gruetzmacher Automobile Co., Shawano, Wis., organized recently, is erecting a large garage. The building will contain a complete machine shop and welding plant.

Headquarters at Dallas — The Giant Tire & Rubber Co., Omaha, Neb., has obtained a permit from the Secretary of State of Texas to do business in that State. Its Texas headquarters will be at Dallas.

Toledo Co. to Move—The Browne Supply Co., Toledo, Ohio, has taken a lease of the corner at Jefferson and Erie Streets and will occupy it about July 15. The company will have practically double the space it now occupies.

New Tire Store—The Louisville Tire Co. has moved into its new tire and accessory store at 666 South Third Street, Louisville, Ky. The company handles Dayton airless and pneumatic tires. F. W. Weisenberger is the manager.

Noxal Co. Makes Change—The Noxal Co. is giving up its sales office at 1400-1402 Michigan Ave., Chicago, Ill., and is combining its sales office with the executive and manufacturing offices at 29 South Clinton Street, change taking place Aug. 1.

Hartford Dealer Moves.—Kingsley & Wetherell, Inc., Hartford, Conn., representatives of the Moon and King, have leased the store at 11 Main Street for a salesroom and will occupy it in the near future. The service station at 59 Congress Street will be retained.

Open New Oil Station—Austin, Bryant & Carter, distributors of A B C oils, will shortly open a distributing station in San Francisco which will supply the trade of all of northern California, including Stockton and Sacramento.

Auto Supply Opens in Seattle—Barsby & Neep Auto Supply Co. opened in Seattle, Wash., recently, and will act as distributors of Master carbureters in the King County territory, besides which they will handle Marathon tires and the complete Johnsville line of accessories.

New Velie Distributors—A. W. and M. J. La Roche have been appointed eastern distributors of the Velie Motor Vehicle Company of Moline, Ill., under the firm name of La Roche Brothers. Salesrooms have been secured at 506-508 North Broad Street, Philadelphia, Pa.

Oakland Company Organized—The Oakland Motor Co. has been organized at Austin, Tex., and it has been appointed distributor for the Oakland in that territory. H. H. Cullen and F. E. Pryor are managers. The company has opened rooms at 300 East Fifth Street.

Places Big Ball Order—The Los Angeles branch of the Ahlberg Steel Bearing Co. has placed an order for 100,000 steel balls, which is only the beginning for the Los Angeles house. The stock inventory shows 150,000 on hand. The branch will keep stock on hand to supply the service stations of twelve states.

New Midgley Tire Agencies—The following firms have taken on Midgley tires: Peterson-Keyes Automobile Co., 401 North Capital Avenue, Indianapolis; Motor Tire & Repair Co., 1817 Grand Avenue, Kansas City; Athena Tire Co., Chicago, Ill.; Kleyn Automobile Co., Duluth, Minn., and Peters & Sons, Ltd., London.

Milwaukee Garage to Add — The Sanger Automobile Co.. 564-574 Farwell Avenue, Milwaukee, Wis., operating one of the largest garages in Milwaukee, and representing the Franklin, is preparing to double the size of the garage by the addition of a full second floor. 50 by 130 ft. The first floor will be remodeled and equipped with electric freight elevators, steel shutter rolling doors, etc.

Babcock in New Shop—The Babcock Automobile Spring Co., Milwaukee, Wis., has taken occupancy of its new factory and store building at 192-194 Milwaukee Street. The company devotes its attention exclusively to replacement of automobile springs and expert repairing, which includes re-arching and re-tempering. The company is Wisconsin distributor for the Tuthill-Titanic spring.

Recent King Changes—Reason & Ross, King dealers in Cincinnati, have changed firm name to the King Motor Sales Co. The Bowman Sales Co., King dealer, has changed its location from McKean, Pa., to Erie, Pa.. where it was located at 18-24 West Fifth Street. Barnhart & Danner, King distributors at Salt Lake City, Utah, have moved into a new establishment at Fourth South and West Temple Streets, and will operate under the name of Lincoln Garage.

Hyatt Roller's New Bldg.—Excavating is well under way for the new office building of the Hyatt Roller Bearing Co. at Cass Avenue and West Grand Boulevard, Detroit, Mich. The building will be the home of the sales and engineering departments of the automobile division of the Hyatt Company. It is to be three stories high and its exterior will be of rough red brick with fine stone trimmings and cornices.

Recent Braender Tire Changes—The Braender Rubber & Tire Co. advise that Ketcham & Lawrie of Newark are no longer their agents in the State of New Jersey. They have appointed the O. A. R. Motor Car Co., 915 South Avenue, Plainfield, N. J., to represent them in that territory. The Tire Shop, 1926 North Charles Street, is no longer representing the Braender Rubber & Tire Co. in Baltimore, but the McGraw Tire Co., Inc., 10 West Oliver Street, Baltimore, has taken the agency for the Braender products for the entire State of Maryland.

St. Louis Cos. Extend.—The Park Automobile Co., St. Louis, Mo., agent for the Chalmers line, has been given additional territory in three states. The new selling territory of the Park company includes twenty-seven counties in Missouri, thirty in Illinois and seven in Kentucky. The Park company will appoint sub-agents in the larger towns of the new territory in the near future. The Weber Implement Co., distributor of Hupmobile and Mitchell cars, has opened a news salesroom for used cars at the northwest corner of Eighteenth and Pine Streets. The building is two stories high and covers a lot of 100 by 109 ft.

Louisville Trade Happenings—The Empire Auto Sales Co., agent for the Empire, has moved its quarters from 437 South Second Street to 624 South Third Street, Louisville, Ky. The Louisville Automobile Exchange, 544 South Third Street, has secured the agency for the Mitchell. Kentucky Motor Car Co., Cincinnati, Ohio, formerly agent for the Oakland in the Louisville territory, has discontinued its Louisville office, located at 725 South Third Street. The Hyatt Auto Repair Co. has opened a repair shop at 211 York Street. The Hanna Gibson Co., 206 East Broadway, has acquired the agency for the Madison Six. The Quick Tire Service Co., Third Street and Broadway, has been appointed Louisville distributor for the United States Tire Co. The Central Garage has opened an accessory store and automobile repair shop at 437 South Second Street. J. J. Gaffney is president of the concern. The Callahan Motors Co., agent for the Chandler, has acquired the Louisville agency for the Scripps-Booth.

VOL. XXXIII NEW YORK—THURSDAY, AUGUST 12, 1915—CHICAGO No. 7

The AUTOMOBILE

2,070,903 Cars in United States

Registrations for First 6 Months of 1915 Show Gain of 334,809—625,000 Car Output Predicted

By Donald McLeod Lay

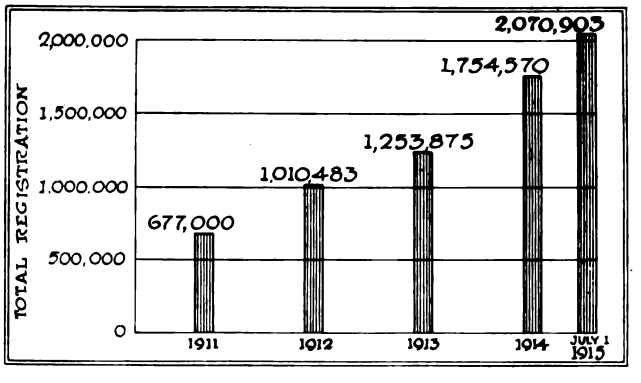
AT last the number of automobiles and motor trucks in the United States has passed the 2,000,000 mark, the total registration throughout the country at the end of the first six months of 1915 showing that 2,070,903 machines are in use between the Atlantic and Pacific and Canada and the Gulf. These statistics represent the most accurate count it is in any way possible to secure, all duplicate registrations being deducted.

334,809 Gain

This stupendous showing at first glance almost overshadows the gain of 334,809 registrations over the 1,747,234 cars and trucks in use at the end of 1914, as reported in THE AUTOMOBILE for March 25. Significant as these statistics are in the registration field, they also serve to indicate the tremendous volume of production which, contrary to many predictions, instead of decreasing, has expanded steadily so that at the present time practically all of our factories are either working night and day or up to capacity. While one concern alone has manufactured over 300,000 gasoline passenger cars, the other makers of this type of vehicle have almost all increased their outputs, while the manufacturers of electric passenger cars and those of trucks of all classes have found their factories taxed to the utmost to keep up with the growing demand.

Predictions as to the total output of these factories during the current year are found to be very conservative when they halt at a total of 625,000 cars and trucks. When one pauses to think that in addition to the 300,000 cars made by one company there are several other concerns building from 50,000 to 100,000 cars yearly, and a larger group of manufacturers who may be credited with turning out from 10,000 to 50,000 cars, it is found that 625,000 is by no means out of the question.

An idea of the remarkable upward sweep of production together with the accompanying increase in car and truck registration since 1910 may be gained from the tabulation at the top of page 273. The detail figures for the individual States together with their totals are to be found in the full page table immediately below. To graphically illustrate the car population of the different States, the map at the top of page 272 shows the distribution throughout the country.



New York	185,767	Virginia	17,799

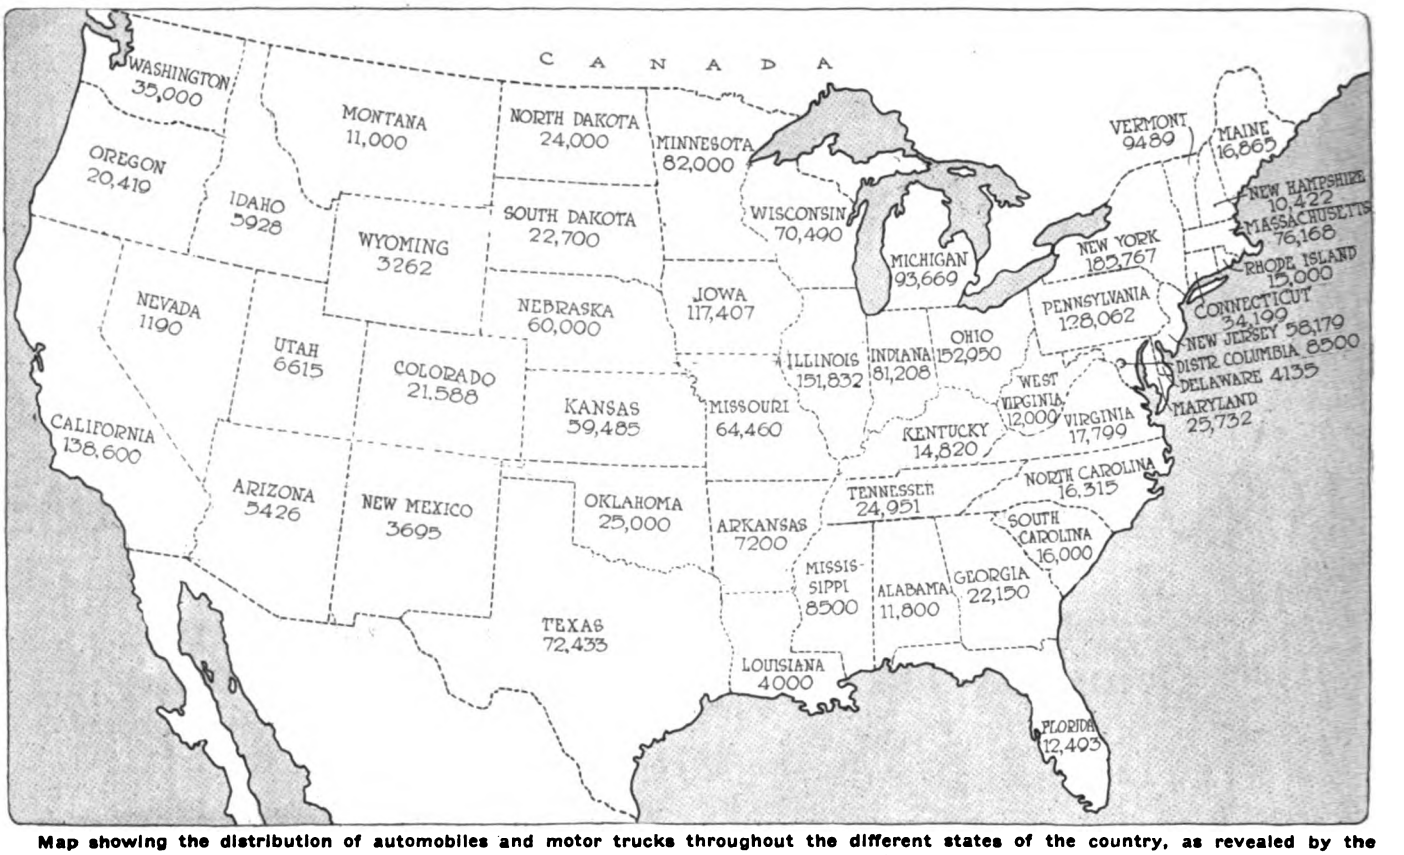
Automobile and motor truck registrations in the various states up to July 1, allowing for duplicate registrations

Farmers Buying Cars

One of the phenomenal features apparent to anyone analyzing the registration statistics for the past two years is the gain made by the States whose populations are for the most part devoted to agriculture. These growing statistics serve to emphasize the reports to the effect that farmers throughout the country and especially throughout the grain belt of the Middle



Map showing the distribution of automobiles and motor trucks throughout the different states of the country, as revealed by the statistics of the registration officials. All duplicate registrations, such as those of non-residents and those due to transfers of ownership of the same car, have been deducted

West, have been buying cars in constantly growing numbers and are still buying them.

Two features of the automobile and motor truck market which may be mentioned as peculiar to 1915 are the war orders for cars, trucks and tractors for the European belligerents and the continued rainy and stormy weather, which, in some sections, has had a very bad effect on the standing crops, road conditions and numerous other factors which must always be considered as influences on the automobile market.

Ohio Shows Largest Gain

Comparing the gains made in registration by the various States during the first six months of 1915, we find that the ratio of increase has been fairly uniform as compared with the registration increases during the calendar year 1914. Ohio shows the largest gain, having 32,096 additional registrations to its credit since the first of the year as compared with an increase of only 36,348 in the previous twelve months. However, it must be remembered that the bulk of the registrations are made during the first six months of the year so that it can hardly be expected that the tremendous increase will continue at its present rate, although it is practically certain that the 1914 statistics will be far surpassed. New York comes second with 25,302 more registrations than at the beginning of the year and comparing well with its gain of 37,302 in 1914. Michigan is slightly ahead of Pennsylvania with 22,085 new registrations as compared with 22,016. Michigan's gain is already larger than its total increase for the entire year 1914, while Pennsylvania's is two-thirds of its last year's figure. Illinois is credited with 19,494 additional registrations while Iowa has 18,000, Wisconsin has 16,108, Indiana has 15,708, Oklahoma 15,640 and California 15,499. Other States showing gains of 10,000 registrations or over since the first of the year are: Minnesota 14,635, Missouri 14,128 and Nebraska 10,000.

Taking up the individual standing of the States with re-

spect to the total number of cars and trucks in use, New York still leads the van with 185,767, all duplicate registrations, including non-resident registrations and cars re-registered owing to changes of ownership, etc., having been deducted from the gross total. Ohio has usurped second place with 152,950, Illinois, which formerly held it, having fallen back to third position with 151,832. California, which was third at the beginning of the year is now in fourth place with 138,600, while Pennsylvania has moved up to fifth place from sixth position at the end of 1914, having 128,062 cars and trucks. Sixth place goes to Iowa, which was formerly fifth, this State having 117,407 registrations when the duplicates are deducted. Michigan has risen from eighth to seventh place and is nearing the 100,000 mark, having 93,669, while Indiana, which was tenth, is now eighth with 81,208. Massachusetts has dropped back from seventh to ninth place which is significant of the more rapid growth of registration in some of the central and western States. The Bay State's total is imposing, however, being 76,168. Tenth place goes to Texas with 72,433, these figures being based on the count made by the Dallas Chamber of Commerce last December, no later statistics being available. Texas has thus moved up one position in the ranks; Wisconsin, with 70,490, has moved from thirteenth to eleventh position. Missouri has gained two places, rising from fourteenth to twelfth, its total being 64,460. Nebraska with 60,000, Kansas with 59,485 and New Jersey with 58,179 are the only other States with registrations of over 50,000. The standings of the States in this respect may be seen in the tabulation on page 271.

Production and Registration Since 1910

1915 to July 1

Registration		Production
2,070,903		625,000 (Estimate)
	1914	
1,754,570		515,000
	1913	
1,253,875		450,000
	1912	
1,010,483		378,261
	1911	
677,000		209,957

Few Systematic Records Kept

Comparatively few of the State registration officials have systematic record keeping departments which enable them to give detailed registration statistics. In other words, while they are usually able to give the total number of registrations, they have no records to show how many are gasoline passenger cars, how many electric passenger cars, how many gasoline trucks or electric trucks. A perusal of the tabulation at the bottom of this page will serve to illustrate this excellently. It will be noted that the total registration is available in practically every case whereas only a few of the States are able to give the detailed statistics, the result being that the totals are far from complete in all these cases. For example, the total number of chauffeurs in the United States of whom records are available is

Car and Truck Registration in Each State from Jan. 1, 1915, to July 1, 1915.

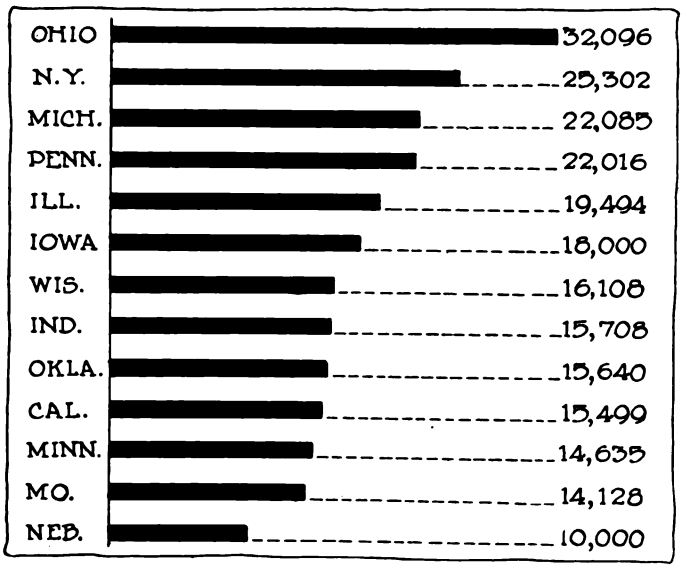
NOTE.—3,500 steam cars, 350 steam trucks included. * Number of cars belonging to residents of other States. ** Number of cars re-registered owing to change of ownership, etc. *** Not listed separately by registration officials. †Estimated by State registration officials. ††Estimated on basis of population with reference to sectional registration. §Registration law runs from July to June. §§Statistics from Dallas Chamber of Commerce, these being only up to December, 1914. Electric cars and trucks are usually included among the gasoline machines.



Thirteen states show increases of 10,000 or over as compared with their registration statistics at the end of 1914

275,746, which, when compared with the 2,070,903 car total, is manifestly far too low.

Five States Have New Laws

Perennial registration is still the rule in the District of Columbia, Utah and Texas, Florida having left this group by the passing of a new law this summer. In Texas, registration, in addition to being perennial, is of a local character, as is the case in South Carolina. Other States which have new laws are Michigan, Nebraska, Oklahoma and Washington. Triennial registration continues to characterize Minnesota while Mississippi is still in the predicament of having its automobile law invalid.

$13,259,440.41 in Fees

As an indication of the extent to which automobile registration fees go toward supporting the State governments, etc., returns from twenty-seven of the forty-nine States show the tremendous total of $13,259,440.41 which has been paid in fees by the automobile and motor truck owners of these States during the first six months of 1915.

27,702 Dealers, Etc.

Another side of the automobile industry which reflects the rapid increase in the registration and production of cars and trucks is that occupied by the dealers, garages, repair shops, supply dealers and charging stations for electric batteries used in the cars. According to the Automobile Trade Directory, the authority in this field, there is a grand total of 27,702 of these in the United States, Canada, Mexico, Hawaii and the West Indies, all overlapping establishments being counted but once. Counting them individually, there are 17,903 dealers, 17,016 garages, 1787 repair shops, 947 supply dealers and 1553 charging stations. The distribution of these establishments among the various States and countries may be seen in the tabulation appearing on page 272.

Recent Court Decisions—Race Horse Injured

By George F. Kaiser

IN a recent Maryland case the owner of a race horse recovered damages against an automobilist, whose car had run down and injured the horse.

The horse was 5 years old, eligible for the 2.24 class; had won all amateur races in which it had been entered, and had come in second in its first professional race. While in Baltimore, being driven to the driving park, it was injured in a collision with an automobile, and when raced later in the season it was unsuccessful. The owner was allowed to show that while it had formerly been level-headed, fearless, a bold racer, and easy to handle, after the accident it was high-spirited, nervous, easily frightened, timid in racing and valueless as a race horse.

The court also held that a photograph of the horse, taken before the accident, could be used in order that the injuries might be pointed out and decided judgment for the owner against the motorist was proper upon the facts.—*Weiler vs. Weiss*, 92 *Atlantic* (*Maryland*) 1028.

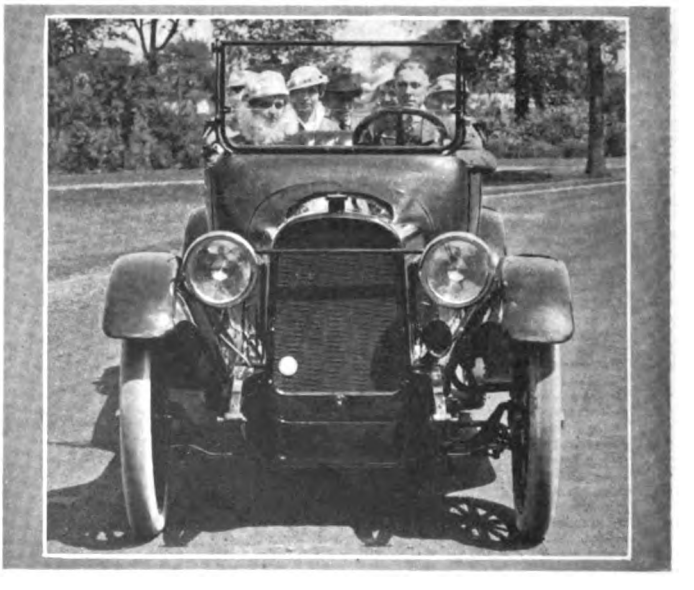
Usual Guarantee

In Kentucky a person suing for breach of warranty on an automobile sold on the "usual guaranty" must show what the usual guaranty was.

In a suit for damages for breach of warranty against a motor car company, the court decided in favor of the company. The other party contended that, the company had guaranteed and warranted the car sold to do good work, to operate well and be capable in every respect; to run over certain territory which he might have occasion to travel; and as the machine was warranted not to be defective, and be suitable to transport him and his passengers safely, but in reality it would not operate or do good work but was worthless as an automobile.

The company claimed that there was a 90-day warranty to replace defective parts, provided the machine was not repaired outside the factory.

The court held that the dealer said a 1-year guaranty on the car was not in absence of evidence of the dealer's authority as an agent, and in the face of proof that he was not an agent competent evidence to show what the usual guaranty was. The proper way to prove the usual guaranty was to call upon the company's officers or some other competent person to testify.—*Johnson vs. Co.*, 169 *S W.* (*Kentucky*) 992.



The 1916 seven-passenger Chalmers six, the chassis of which was described in THE AUTOMOBILE for July 22

Possible Troubles With Aluminum Motor

A Brief Consideration of Some Smaller Details and Their Seriousness

By A. Ludlow Clayden

SINCE writing last week on the subject of the possibilities of aluminum that have been neglected, it has been possible to obtain the opinion of one of the largest of motor manufacturers, who was also one of the first to experiment with aluminum cylinders, and the engineering opinion in this large plant seems to be capable of summation into the idea that the ultimate triumph of aluminum depends upon nothing but its price. That the aluminum motor is a better motor by virtue of its light weight and by virtue of its better conductivity to heat is undeniable, and it appears that the naturally anticipated difficulty of porosity is not a real trouble.

Suits Valve-in-Head Motor

There is no doubt, however, that the aluminum construction lends itself best to the overhead type of valve gear. In an engine with detachable cylinder heads any porosity of the bore is cared for by the cast iron liner, the head can easily be thick enough to remove all risks and both main block and head are simple castings, which again cuts the chances of porosity developing. At the same time it is reasonable to suppose that practice will make perfect in this as in all other things, and the aluminum cylinders of to-morrow ought to be better than those of to-day.

Curiously, the idea of casting the aluminum around the iron liners is not favored by either the founders or the engineer who has done most experimenting with aluminum motors. Broadly the idea is that the absolutely even thickness of the iron liner makes for freedom from distortion and that in making a composite casting it would be impossible to use a liner nearly so thin as can be done by the other method. Also it is not easy to cast the aluminum around so large a mass of iron as would be necessary.

In the machine shop the task of boring out the aluminum to receive the iron liner is a quite light one, as a rapid cut can be taken and the fitting of the liner is not difficult. Liners which have been put in cold while live steam was blown around the aluminum jacket have shown no tendency to loosen up in service and really there is no reason why they should do so as there is very little axial force transferred to the cylinder walls by the well-lubricated piston.

More dubious perhaps, is the durability of the cast iron valve seats that are cast in place as shown last week in the photograph of a block prepared for an L-head motor. It would be permissible to wonder whether the constant hammering of the valve may not loosen the iron in time, but even should it do so there are other ways of tackling the problem. For instance the valve seat and the valve stem guide might easily be a complete part, just as the cylinder liner is a complete part, and such a piece could be secured in a previously bored out seating in the aluminum.

Another point for speculation is the proper material for valve caps where an L-head design is employed. From the expansion viewpoint aluminum should be the best material and it would also have the advantage that it would carry heat away from the spark plug much better than a steel or iron cap, but it seems probable that the durability of the screw thread would be insufficiently good, considering how tightly valve caps have to be screwed in.

This last difficulty remains, whatever the material of the cap, so it looks as though the designer of an L-head job with aluminum cylinders would have to devise some novel way of securing the valve caps without using fine pitch screw threads. Of course the adoption of a detachable head does away with the difficulty, but there are many engineers who dislike to abandon the individual valve accessibility that is given by the use of valve caps.

Another thought suggested by discussing the subject, is that some engineers have kept away from the overhead camshaft type of motor because they think it cannot be made without a considerable increase of weight over the normal type. Whether this is true or not, it follows that this drawback is removed by the possibility of employing a lighter metal.

Yet another question that has arisen is the problem of fastening together the upper and lower portions of an aluminum engine with a detachable cylinder head. Often it is not too easy to find accommodation for more than the minimum essential number of studs and the softness of aluminum would call for an increase in the number so that the stress on each might be lessened. Here again the objection seems to be more imaginary than real, judging by experience as it exists at present, but a more serious possibility is that a stupid person could easily bend an aluminum cylinder head by tightening down too much on one stud before taking up the others. With a cast iron head there is danger of cracking the casting this way, but it is not so likely a happening. There may be nothing in the objection, but if there were it would seem advisable to devise some dodge which would enable the studs to be replaced by bridge pieces or clamps of some kind. Several possible ways suggest themselves but the chances are that they need not be considered unless practice proves the contrary to be the case.

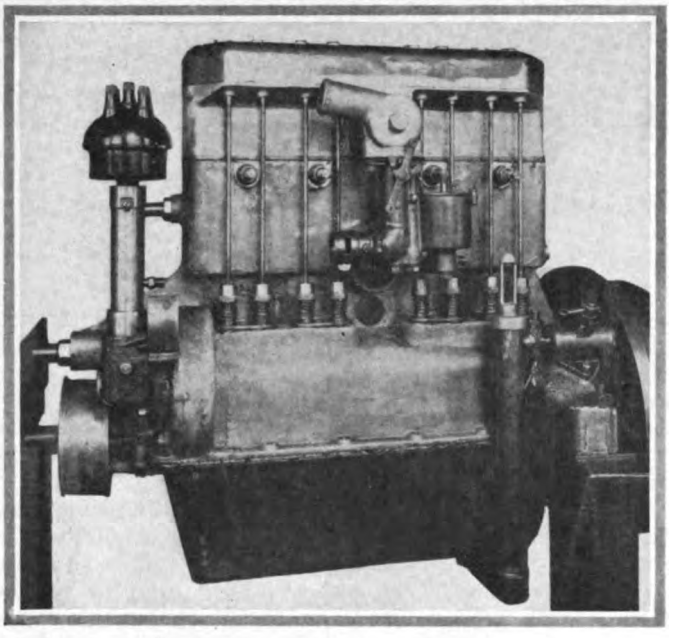
Some Useful Data

A point which will arise naturally in the mind of an engineer when first he thinks of using aluminum cylinders is that the co-efficient of expansion for aluminum is greater than that for cast iron. Examining the actual figures for a moment, the co-efficient of expansion for aluminum is 0.000023. Assuming that the motor operates between the temperatures of 32 and 212 deg. F., which is an over statement, the expansion per foot would be 0.0023 ft. or just under 28 thousandths inch. If the distance between the cylinder bore centers is 6 in. the maximum displacement on a large six-cylinder motor would not exceed 30 thousandths at most, as the range of temperature over which a motor operates is much smaller than from 32 to 212 deg. F. Per cylinder the amount of axial displacement would therefore be about 4 to 5 thousandths which the normal end play on a connecting rod bearing exceeds very greatly.

Another point is the amount which must be allowed for shrinkage in casting, this being 5/32 in. per foot as against ⅛ in. for cast iron, not by any means a serious matter.

Prefers Steel to Aluminum

PORT JEFFERSON, L. I., N. Y.—Editor THE AUTOMOBILE:—The question of aluminum and its uses in the make up of the modern automobile as outlined by A. L.



Another view of the Sterling aluminum motor illustrated and described in THE AUTOMOBILE for Aug. 5

Clayden in THE AUTOMOBILE, Aug. 5 issue, will no doubt open up a discussion which should establish something of value in reference to this material and its general use.

My experience conflicts with his conclusions and recommendations in a great many ways. I am not forgetful, however, of the fact that we may consider the results to be obtained from several different angles which would more or less influence the obtainable results to be had by the use of aluminum. In explanation of this statement in the case of a low-priced automobile with a comparatively low range of efficiency required the generous use of aluminum would without doubt result in a material gain in efficiency both in up keep and roadability, but to produce increased efficiency by reducing weight and increasing the power output disregarding the gains as a result of weight reduction aluminum would be the last metal used.

In the first instance it would mean the easing up of work required and from a predetermined unit with given capacities it would result in a net improvement, but in the latter case the object would be to refine the power plant bringing it up to a higher standard in an endeavor to generate more power with a smaller unit. This would mean increased ability demanding higher stresses and higher thermal efficiency. Carrying this theory to a point within practical limits would result in reducing the power demanded, which together with the increased ability would result in a net gain many times greater than an attempt to lessen the weight through the use of aluminum under the same conditions as mild steel and cast iron are now used.

Difference in Expansion

Assuming that one adopts the second plan I do not believe the use of aluminum would be permissible in any of the vital parts about the motor. The first great handicap is the vast difference in expansion between this metal and any of the stronger steels or even cast iron, which means that the use of liners or inserts is practically prohibited, and still further considering the fact that while aluminum is only about one third lighter than steel its strength is less than one-sixth as great as that of modern steel, the result being that most any part of a motor or car can be made lighter by the use of steel. My impression is that if two engineers of equal ability were given free hand to design an automobile of a given capacity one to be confined to the use of steels and the other to the use of aluminum, cast iron and mild steel, that the former would win out by a large margin so far as ability and lightness are concerned.

Referring to the Sterling motor used in the article as a criterion of the use of aluminum I would doubt very much the ability of this motor to withstand being brought up to a high efficiency for any length of time. The insertion of a cast iron sleeve for the cylinders would to my mind destroy any gain to be derived from the conductivity of aluminum so far as dissipating internal heats is concerned inasmuch as the joint would prove a non-conductor to a far greater extent than the aluminum would improve the conductivity.

There appears only one possible condition that might make this type of construction possible and that is that owing to this joint the inner sleeve would work under a much higher temperature than the outer walls, which might overcome the great difference in the co-efficient of expansion between the two metals, but even should this assumption prove to be a fact we are still up against the tremendous range of temperatures that exist in the operation of a modern automobile, and whether or not these could be compensated for by prolonged experiments is a question.

Redesign to Reduce Weight

Since the total weight of this motor is not given it would be quite hard to give an estimate of what could be saved in design, but it does not follow the best design for lightness, and my impression is that the motor could be re-designed and be made lighter by using iron and steel throughout than it is as shown with the use of aluminum, and there is no doubt but what its power output could be increased per pound weight considerably, and after all this is the unit of measure that must be considered.

The use of aluminum and aluminum alloys for pistons is certainly a mistake so far as my experiments have led me to believe. That they can be made at less cost than a steel piston or cast iron of equal weight is a fact, but when it comes to the question of weight, disregarding cost, the steel is far ahead of aluminum. Besides with the steel piston a much higher thermal efficiency can be had than with the use of aluminum. In the case of the Sterling motor if the aluminum cylinders are lined with cast iron the conductivity of the aluminum piston loses its value to a great extent and my impression is that a very low compression ratio would have to be used in order to keep from melting the pistons.

The use of aluminum to any great extent for important chassis parts has also received a setback in my estimation as a result of my later experiments along this line. I am thoroughly convinced that road shocks run much higher at times than any of us estimate. My conclusions along these lines are brought about by the use of aluminum in chassis parts. Inasmuch as failures appear at long intervals apparently not consistent with fatigue or ordinary use while none of the steel parts as used in my last two years of experiments have shown a sign of failure, so that by using aluminum I believe a factor of safety of twenty to one would have to be adhered to. This would mean that the weight of your parts would be far in excess of steel under the same conditions when you use a factor of safety of ten to one figuring from the elastic limit of steel rather than its ultimate strength. A more convincing argument can be had when confined to some specific case, a result which we hope will be had if the subject can be kept alive in the columns of your paper. —Finley Robertson Porter Co., Inc.

Aluminum Too Porous

DETROIT, Editor THE AUTOMOBILE:—Relative to the use of aluminum castings for cylinders, for motorcars, permit me to call to your attention that in 1906 the Oldsmobile Co. used a water pump on the forward end of the crankcase. This pump was of the key type, the body of the pump being machined

directly out of the aluminum crankcase. In certain sections of this country the water was of such a character that it rapidly ate through the aluminum and permitted leakage of the inside of the crankcase. This was so serious that the Olds company had to make a change in design and incorporate a pump as a unit, bolted to the face of the crankcase.

I would hesitate very much about attempting to repeat this performance, in running water directly through the aluminum. I realize that there are a number of intake manifolds, waterjackets, and there is evidently no trouble in the use of aluminum for this purpose. However, my direct knowledge of the subject is of a very limited nature, and I would hesitate to make any claims that the water used in the various parts of the country would not ultimately eat through the aluminum and destroy the casting. Of course, an owner could be instructed to use distilled or rain water in the cooling system, but this is imposing a hardship that is fully as disagreeable as instructing the owner to use distilled water in the battery once a week. This is one of the hardest problems we have had to combat since the incorporation of the electrical starting and lighting system on the modern automobile.—C. C. Hinkley, engineer Chalmers Motor Co.

History of Aluminum

PHILADELPHIA, PA.—Editor THE AUTOMOBILE:—My recent experiences have not included the pistons that I feel sure ought to be of aluminum. I early foresaw the value of this light metal and knew something of the cycle frames cast in one piece that were stronger than steel ones. I began using aluminum in 1896 and that winter tried cylinder heads and waterjackets of it. Early in 1897 I tried a few pistons as large as 6 in. diameter in a water-cooled job and some small ones in a motorcycle engine. Also used it for rear-axle housings. The results were bad. The metal was found to be very porous. It was clear the founders did not know how to handle it. Gas could be heard bubbling through it.

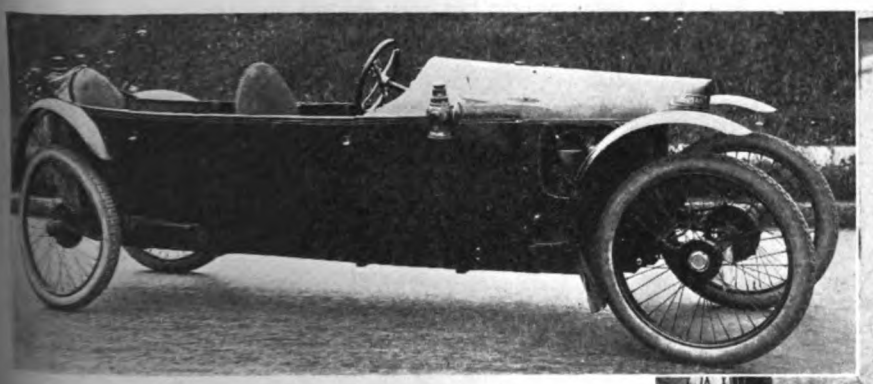
The rear housing did not show much strength at the heavy end where it should have been strongest and was perfection at the light end where it first cooled. The motorcycle pistons did better but fearing to take the chances they were all abandoned. But I still remembered the cycle frames. They were cast in iron molds and before pouring the molds were heated above the melting point of the alloy. After pouring they were cooled by a spray beginning at the bottom. This allowed the molten metal to flow to the cooling portion and fill up the shrinkage which ordinarily tears a casting to pieces. Surprising strength was gained by this process but the molds did not last long. With better steels to-day this should not bother. It certainly has a big future.—Charles E. Duryea.

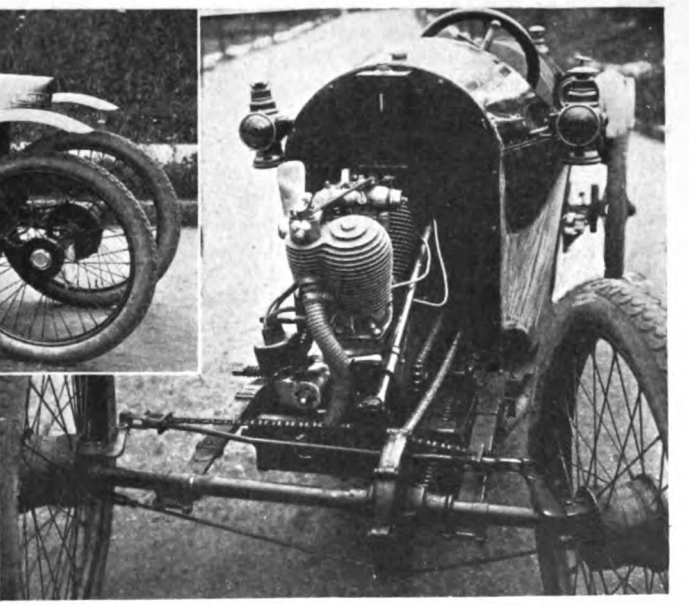
Likes Aluminum Parts

SANDY HOOK, CONN.—Editor THE AUTOMOBILE:—I notice in the current issue an article on the lightening of motor car parts and therein a reference to the adoption of aluminum alloy connecting-rods, I might say that I installed magnalium rods in my car, model O, Knox, over a year ago, these rods have run close to 6000 miles without any attention whatever and in connection with the change to magnalium pistons reduced the weight of the reciprocating parts 27½ lb. I consider this a very pronounced reduction and to get a further idea as to the possibilities of the metal have designed a piston for this motor, 4⅞ in. bore, that figures 11⅝ oz.

I am regularly turning out Ford pistons that weigh 13 oz. and have installed alloy pistons in quite a number of other makes of cars with very satisfactory results. The magnalium pistons in my car were installed three years ago and have run nearly 20,000 miles.—A. C. Griscom.

Morse Cycle Car Has Front Drive

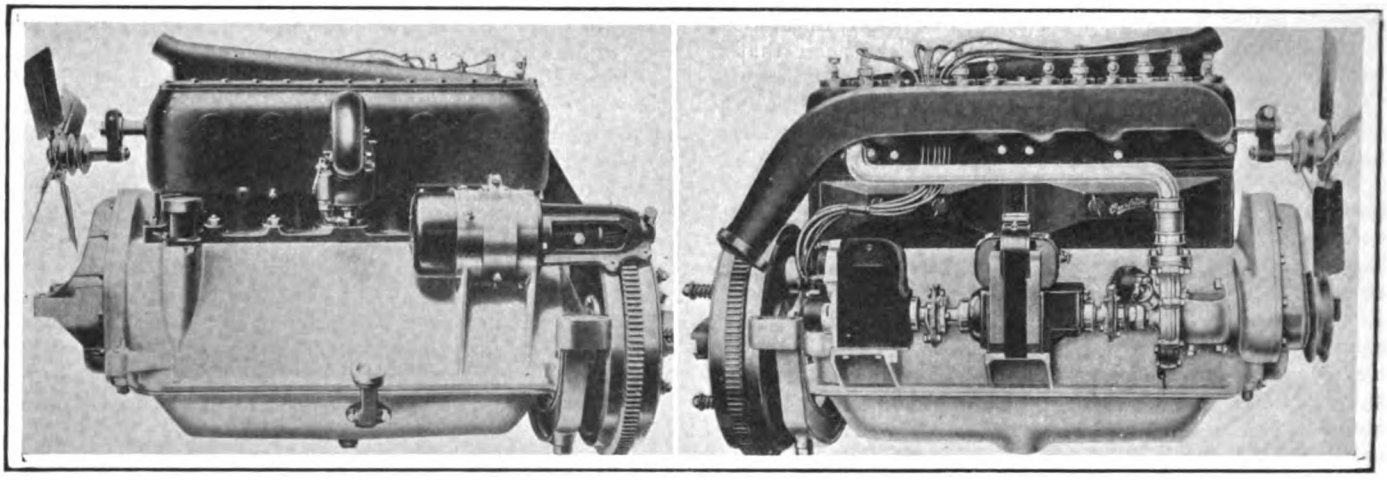




FOR those who believe in the cyclecar, the product of the Morse company, Pittsburgh, Pa., which has just announced a car of this type with tandem seating, narrow tread, and two-cylinder V-type engine, will be of interest. The car is shown in the accompanying illustrations and is said to weigh but 600 lb. It is featured by a front drive, so arranged that the power plant is assembled as a unit in front, the drive being transmitted to the front axle by chain, the efficiency for which is claimed to be 95 per cent.

A claim of 40 to 50 miles per gal. of gasoline is made and it is stated that it is possible to travel from 50 to 60 m.p.h., while owing to the low center of gravity, the tendency to overturn is very slight. The hill-climbing ability of the car is claimed to be very good and according to the showing made at the recent contest at Uniontown, where the little car secured sixth place in the event for cars up to 230 cu. in.

The change-speed mechanism provides two speeds forward and one reverse. The brakes are 8 by 1⅜ in. mounted on the rear wheels and lined with Raybestos and there is also a brake on the transmission communicating to the front wheels. The equipment includes an Atwater Kent system for ignition, Schebler carbureter, a full set of lamps for the side and tail, with a top, gas tank and gas headlamp at $30 extra. The price of the car is $350 with standard equipment, and it is mounted on a 105-in. wheelbase, with 28 by 3-in. tires, and is provided with a two-passenger tandem-seated body.



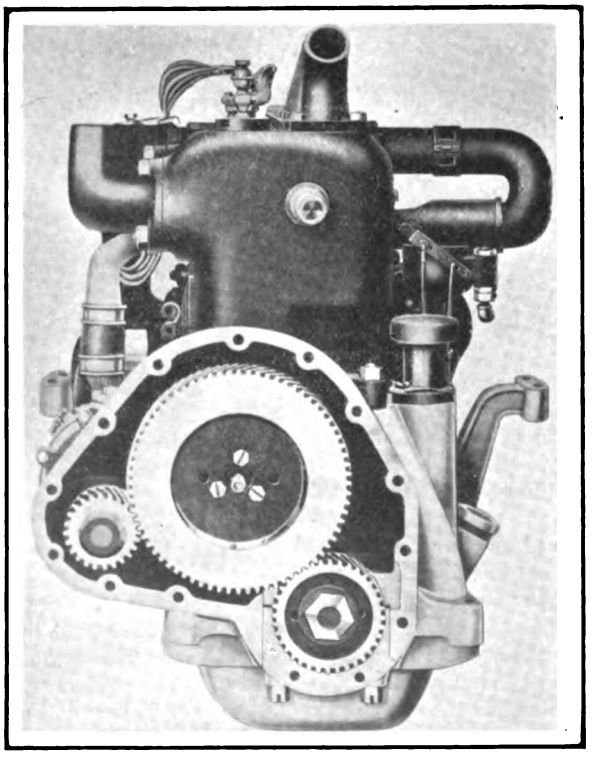
Left—Shows high mounting of starter and carbureter. Right—Gives a good idea of the valve accessibility. The oil pump can be seen just above the coupling between the water pump and generator

Overland Brings Out New Six

Chassis Is Similar to 1915 Model—Motor Improved in Detail—New Design Body Has Straighter Lines

At present the Overland plant at Toledo is producing completely one type of car only, the four-cylinder model with poppet valve motor. The Knight motors for the Willys-Knight come from Elyria and the sixes from Detroit, so the assembling shops and the test shop at Toledo are not interfered with by the necessity for handling more than one model of engine. In the chassis assembly the frame designs are changed a little so as to suit the different motors and the effect is that the assembly operations differ very little indeed whether the chassis has the standard four, the Knight or the six. This system makes for efficiency to a marked degree and means that the three models can be produced with extremely little special organization in the main factory.

Though not made in very large quantities as quantities are reckoned by the Willys-Overland Co., the Overland six is none the less a popular car. This year some 7000 or so are scheduled, and the car would certainly sell readily in larger quantity as the price, $1,145, is quite low as compared with the style and finish. The main characteristics are a smooth acting motor, with ample power and excellent acceleration, a large and very comfortable body, particularly good springs and conspicuous accessibility. In running it is very quiet even after covering a distance equivalent to more than an average year's use, the model car, which has been run over 12,000 miles by the factory testing staff, being altogether devoid of small rattles or squeaks, either from the chassis or from the body. Considering the harsh way in which factory test cars are usually treated, this speaks very well of the body framing in particular, as an old body without a door rattle is far from a common thing to meet.



Front end of motor showing new timing gears, oil filler and horizontal carbureter with hot air supply taken through cylinder block

Several Changes in Motor

The 1916 motor is considerably different from the 1915 six, having helical gears for timing drive instead of the spiral gear arrangement used previously. By this change some weight has been cut out and the engine rendered much neater and more accessible. With an S. A. E. rating of 29.4 the motor dimensions are 3.5 by 5.25 in., giving a piston displacement of 303 cu. in. The maker's rating is 45 hp. and this the motor should be easily capable of developing, as it will run at high crankshaft speeds.

Regarding the valve side of the motor, it will be seen that the generator and magneto are driven in tandem from the water pump shaft, and that all three accessories are placed low enough to clear the valves of obstruction. It should be added that the accessibility is actually better than it appears even, as the generator stands well away from the side of the crankcase, giving room for the manipulation of a tappet adjusting spanner. The use of leather disk couplings between pump and generator and between generator and magneto entirely prevents noise in the drive and also eliminates the possibility of slack arising, which is important in a tandem drive, for any lost motion between the front

end pinion and the magneto would necessarily affect the timing of the ignition.

In the valve side view of the engine the large exhaust pipe is noticeable. This has a vertical division inside, extending from about the middle of the length right back to a point just above where the exhaust pipe is attached. The purpose of this division is to separate the discharge from the three front cylinders so that exhaust strokes take place on alternate sides of the division, the idea being to prevent interference which might create back pressure.

The reverse side of the motor bears the carbureter and the starting motor, the former being a special form of horizontal instrument attached directly to the cylinder block where it is extremely accessible. All the air for the carbureter is drawn right through the cylinder casting, entering at a hole concealed by the exhaust manifold and reaching the carbureter by the curved pipe seen in the reproduction.

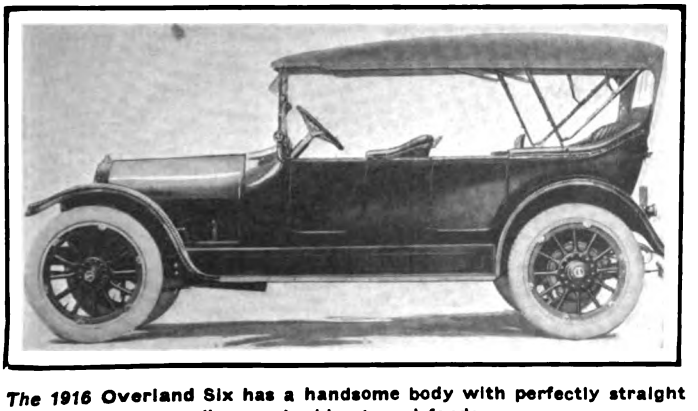
It should be noticed that the starting motor is placed high up, where it is out of the way of dirt and the Bendix drive is accessible for the occasional lubrication which it needs. On this side of the motor also are the oil filling cap and the level indicator, so all the ordinary needs of the motor can be attended to by raising only one side of the hood.

Lubrication is a combination of force and splash, a plunger pump operated from the camshaft sending high pressure to the main crankshaft bearings, the pump shaft bearing and the timing gears. Troughs catch the overflow and dippers on the connecting-rod caps distribute spray to all parts of the motor. A large diameter shaft and very rigidly supported bearings eliminate vibrations with a remarkable degree of success.

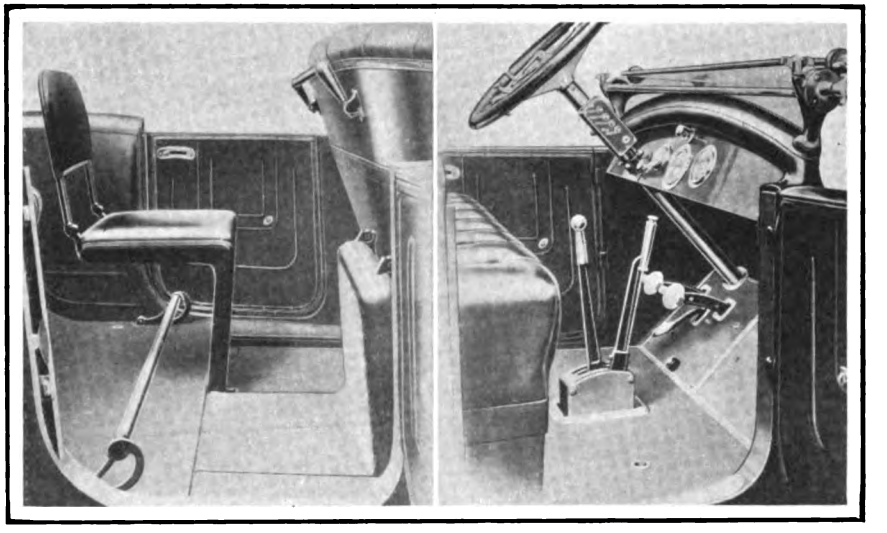
Clutch Has Multiple Springs

An aluminum cone with a leather facing is used for the clutch, but there are three springs instead of the more usual one. Spaced equally around the clutch cone these light springs are ideally accessible for adjustment and there is no need for the exercise of any very special precaution to see that all are at the same tension, since inequalities are compensated for by a floating spider inside the flywheel. Cushion springs beneath the leather are used to ease the engagement, which is very smooth and soft. A special point is made of the light pedal pressure required which is available for drivers of any stature by virtue of the adjustable pedal plates.

Though the after part of the chassis is similar in appearance to the well known Overland four, the rear axle is strengthened in proportion to the heavier stresses it has to bear. It is a floating type with the road wheels mounted upon double rows of Timken taper roller bearings. For the differential the four-pinion bevel pattern is used and there are large Timken bearings to support both it and the crown wheel. The driving shafts can be withdrawn through the hubs, and the axle case is strengthened by the use of truss rods.



The 1916 Overland Six has a handsome body with perfectly straight lines and wide, domed fenders



Left—Type of folding seat used in Overland Six. Right—Every detail of the control grouped for the driver's best convenience

Located on the rear axle is the three-speed ball bearing transmission, and there is a torque tube containing the propeller shaft, in accordance with Overland practice. The single universal is located well forward in the chassis where it is completely protected and easy of access for lubricating purposes. Quite a feature of the car are the large brakes which provide great arresting power with smoothness of action, the service brake in particular having a wonderful grip with quite light pedal pressure. Ample width of drum and plenty of surface for both the external and the expanding bands is the secret, combined with direct pull rods and no lost motion or heavy pull-off springs.

Convenience of Control

A point in the design which has had special study is the location of the controls which the driver requires. Thus the accelerator pedal is situated in the natural resting place for the right foot, the right hand rests easily upon either the gear or emergency brake levers and the lamp and ignition switches are all together in a little control box clipped to the steering column. The speedometer dial is central in the cowl board, flanked by the ammeter and the oil pressure gage, all being illuminated by a dash light which is always burning when the headlights are in use with or without the dimmer. It may be added that all the switches can be locked by a turn of a key at the bottom of the control box, so preventing interference with any circuit. For operating the starter there is a toe button, as the Bendix drive needs only a switch action for its complete operation.

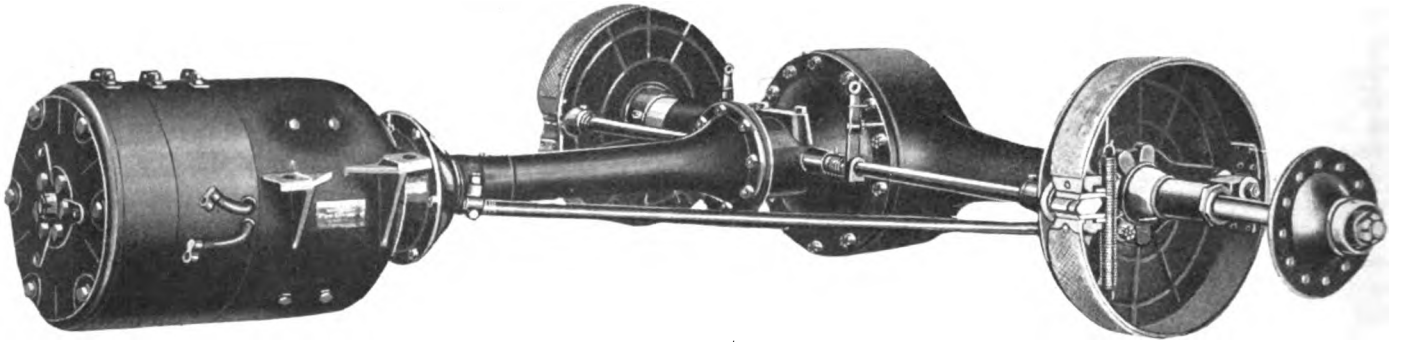
Plenty of Room in Tonneau

It is said that the springs are especially good and their easy action is aided by an ample depth of upholstery, but the long, three-quarter rear springs do not create much roll when rounding a curve at high speed, and it is also noticeable that the rebound is slight. For this reason it is possible to sit back comfortably on a rough road and make use of the leg room.

The standard equipment includes all the usual accessories and a spare demountable rim, tires being 35 by 4½, with nonskid treads on the rear.

Improved Detroit Electrics Lower in Price

Spiral Bevel Drive Optional—High Quality Chassis and Bodies



Power unit showing direct drive connection between motor and worm bevel drive. Note large expanding brakes in hubs

WHAT might be regarded as a new phase in electric car manufacture begins this week with the announcement of sweeping reductions in the prices of all of the models of Detroit electrics, made by the Anderson Electric Car Co., Detroit, Mich., the activities of which in its field are a good indication of the trend of this branch of the industry.

The Detroits are to sell at prices ranging from $1,975 to $2,275, which means reductions running from $600 to $725, depending upon the model. Along with this significant move, Anderson makes the statement that production is to be practically doubled for the coming year, this being the main reason for the large price cuts, as the cars are quite evidently not cheapened in any way. They are, as a matter of fact, more highly refined than ever.

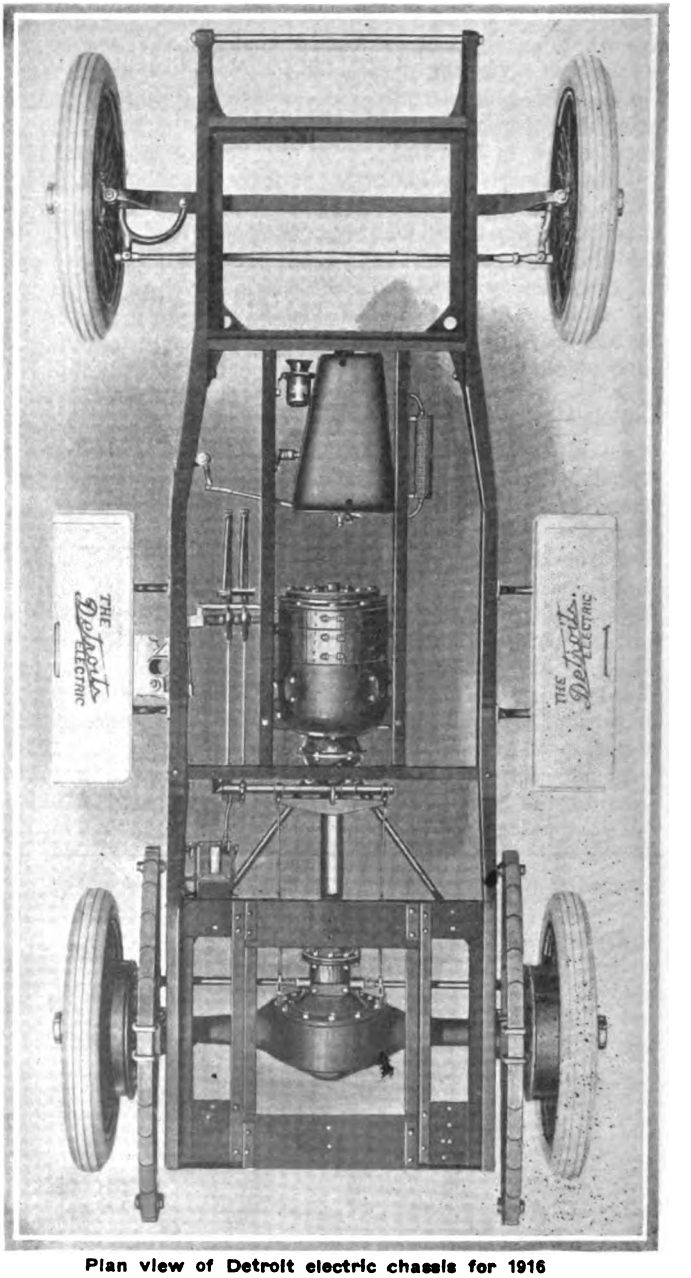
As an indication of the standardization that is going on with the Anderson company, it has adopted a one-chassis basis of production, with five different types of bodies fitted thereto. This is a noteworthy situation from a manufacturing standpoint.

The 1916 Detroits comprise six models. Briefly, these are model 61, which has been reduced from $2,600 to $1,975, and is a four-passenger brougham; model 60, a five-passenger double-drive brougham which formerly sold for $3,000 and is now $2,275; a rear-drive five-passenger brougham, model 59, which has been cut from $2,950 to $2,225; model 58, formerly $2,950 and now listing at $2,250, also a five-passenger brougham, but having front drive; a four-passenger inclosed type, known as model 57, which formerly cost $2,850 and is now $2,175; and model 56, which is a popular cabriolet style for three-passengers and sells at $2,075, as compared with its old price of $2,650. There is nothing changed in the basic construction of these cars, as they continue to use a 4-hp. series wound motor with shaft drive to the rear axle, and 42-cell lead battery equipment.

Optional equipment is given for the rear axle, for beside the standard type of worm drive used in the 1915 models there is being offered a floating spiral-bevel gear rear axle with a reduction of 6 to 1. Ball bearings are used in the construction, and the differential gears are cut from chrome-nickel steel.

Refinements Numerous

There are, however, a number of refinements worthy of notice, all tending towards greater interchangeability of parts throughout the line of bodies, and to even better body work, performance and convenience. For instance, the glass



Plan view of Detroit electric chassis for 1916

in the bodies is mounted on thick rubber, with the channel dovetailed in such a manner that it is said to be impossible for wash water or the most driving kind of rain to find its way within the body. Door locks have been fitted which may be operated from either side of the car, both from the inside or the outside, this having an obvious advantage.

Cut-Out Design Improved

The current cut-out has been entirely redesigned in order to adopt the more efficient knife blade type of switch and this new design has proved itself most reliable after much testing. The top cover of the cut-out box is easily removable for inspection purposes and, as another indication of accessibility, taking out two screws allows the removal of the bottom of the box, to which the contacts are fastened. This makes it simple to inspect or work on the contacts.

The third speed shunt has also been made of greater capacity, by using a larger diameter of wire. This acts principally to increase the rate of travel on third speed and it really makes a better speed range for, with the new wiring, the third speed is exactly half the difference between the second and fourth speeds, measured in miles per hour.

All the bearings in the controller have been made of the self-lubricating type, and another controller change is a new design of cover and the use of a pressing for that member. The resistance for the adjustment of the motor brake, together with the meter shunt, has been mounted on the controller base and underneath the cover. A piece of felt running the length of the controller frame and saturated with sperm oil provides for automatic lubrication of the controller drum so that the drum contacts wipe across the felt which keeps the controller blade constantly clean and lubricated. Leakage of the current is prevented through the oiled felt by now mounting the lubricator in a separate casing insulated from the controller base.

No change in principle has been made in the motor brake. Refinement details however include the use of a Raybestos covered disk mounted upon a screw thread, which allows adjustment for wear. This dispenses with the twelve or fourteen adjusting washers which were used on the previous models of motor brakes. Improvements have also been made by the addition of more brake material, which allows a greater degree of wear without the need for frequent adjustment.

Brakes on rear hubs are of the internal expanding type, size 2½ by 16 inches, and are operated by merely pushing foot brake pedal forward. To the left of foot brake pedal is located a smaller pedal. Pushing this small pedal forward with the foot applies rear hub brakes and simultaneously cuts off the power through a knife blade cut-out switch. It also operates ratchet which sets brakes. When brakes are set in this manner they cannot be again released until controller handle is in neutral driving position.

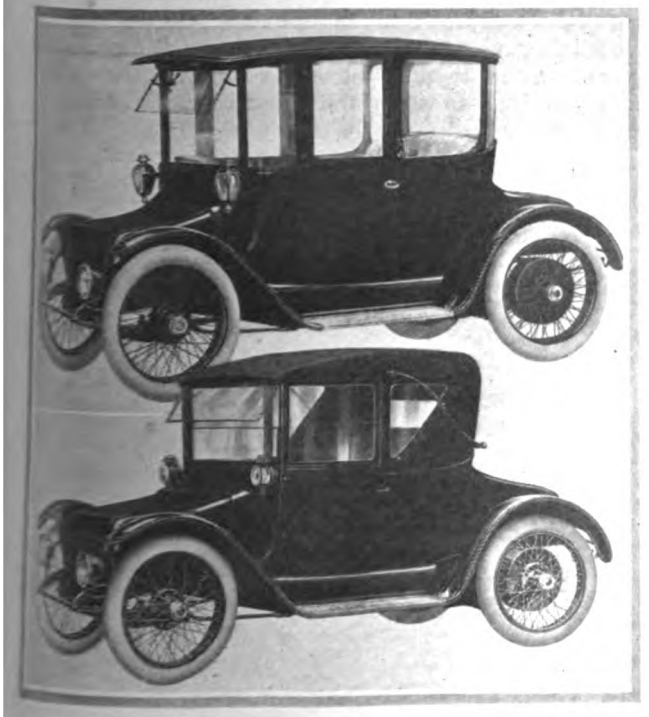
A new design has been worked out for the first speed resistance. The resistance coil of heavy wire is supported on the frame at each end, so that there is a circulation of air all around it. This increases the heat radiation, and affords a considerable saving in weight.

Refinements have also been built into the controller mast and its universal joints, the latter now being of heavier construction than it was, with an adjustment provided for wear. A bar of spring steel is used to connect the joints so that there will be a slight yielding in case an inexperienced driver should apply the motor brake too harshly. The steel, however, is stiff enough to be rigid under all ordinary driving conditions. This construction is to safeguard the bending or disarrangement of any of the other parts of the controller mechanism.

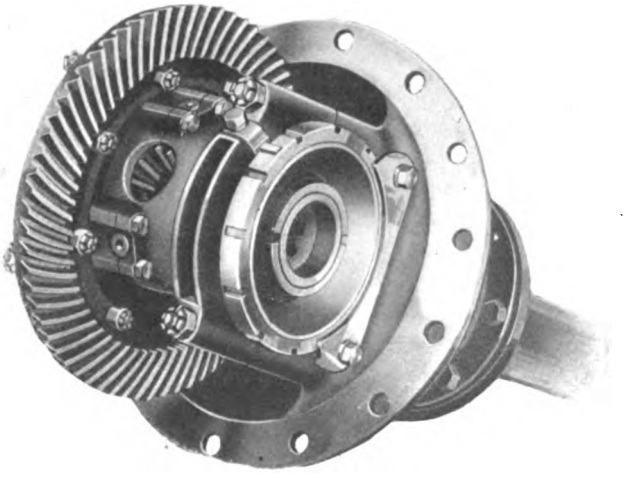
Battery equipment consists of 42 lead plate cells of 15 plates each, and is contained in eight trays arranged lengthwise of the car. This method of arranging them allows for identical trays, and very accessible connections upon raising the battery hoods. Weight reduction of about 50 lb. has been accomplished in the battery construction.

Wide Choice of Body Styles

Enumerating some of the special features of the several body types, the Anderson company calls special attention to the fact that model 61 is especially applicable for city driving, due to its compactness and the ease of handling in traffic. The operating levers are mounted on the left of the rear seat, and steering is accomplished by the driver's right hand, while the shorter lever does the controlling. Theft of the car is prevented by a nice feature whereby the levers can be swung upward into a vertical position and locked against operation. Three persons can be accommodated on the wide rear seat, and a fourth passenger is taken care of by a revolving Pullman-type of chair in the front right corner. Wire wheels or wood type are optional, as are also Goodrich silvertown cord tires of 34 by 4½ size, or Motz cushion tires. Wheelbase of all models is 100 in.



Above—Model 57 four-passenger Detroit electric rear drive brougham which sells for $2,175. Below—Model 56 three-passenger cabriolet which is listed at $2,075



Details of spiral bevel worm floating rear axle which is optional on the new Detroit electrics. This has a reduction of from 6 to 1 and ball bearings are used in its construction

New Commerce Delivery

Strength and Sound Design Features of Chassis—Every Detail Made for the Job

IT is an accepted maxim that the best sort of vehicle to use for the transportation of goods is one built for the purpose and not one adapted to suit it. While many converted pleasure chassis do give good service as delivery cars it stands to reason that a type with twice the strength cannot fail to give more enduring service.

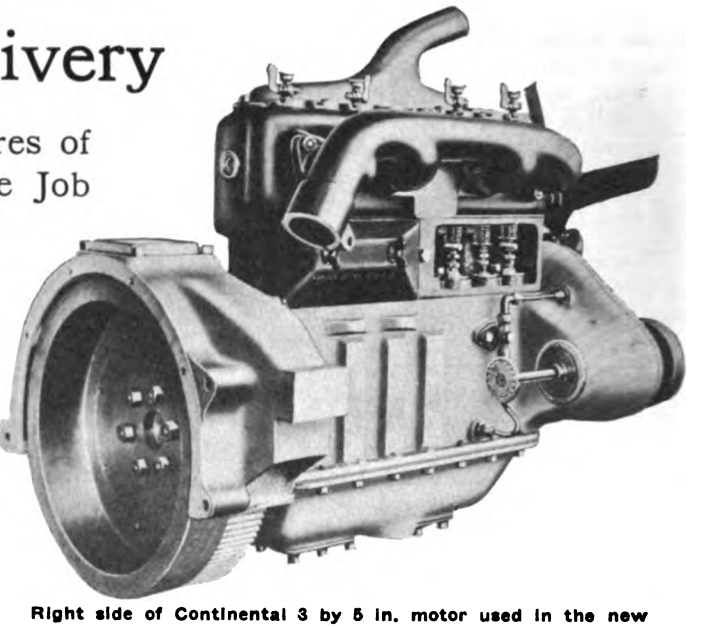
It is with this idea that the Commerce chassis has been built, but with the additional thought that the retail storekeeper or dealer does not want to pay a high price, in fact a high first cost may easily make it impossible for a car to be used where it would be truly valuable.

Good Units in Assembly

The Commerce Motor Car Co., Detroit, Mich., has picked good units such as a Continental 3 by 5 in. motor. Gearing and clutch come from the Detroit Gear & Axle plant, being just as much intended for rough handling as is the truck motor, while the bevel driven rear axle is a special construction calculated to carry a big overload. The rated capacity of the car is 1,500 lb. and plenty of space is allowed, as instance the dimensions of the floor of the panel van which is 88 in. long and 44 in. wide. As to the frame, this is good stout steel and the section 4⅝ in. deep by 3⅛ in. wide, these dimensions being maintained for nearly the full length and the amount of tapering off confined to the front end which has only the engine to carry.

Thoroughness and simplicity are the keynotes of the whole machine the driver having as little as possible to care for. Thus the motor is cooled by thermo-syphon, the special design of radiator and the amply large pipes making this system perfectly satisfactory and eliminating the water pump which always needs some attention. For lubrication a sight feed is introduced in the feed line from the oil pump and all the oil for the rear crankshaft bearing passes before the eyes of the driver.

Brakes, which of course, need adjustment from time to time have settings at three points, so that their efficiency can be maintained at the full till the last scrap of lining is used up. On the bands themselves there is a setting to keep the last lever in the position of best pulling power. Then there is an adjustment on the clevis of each pull rod which cares for the countershaft lever positions, and lastly there is an adjustment at the front end which cares for small degrees of wear and can be got to with the utmost ease.



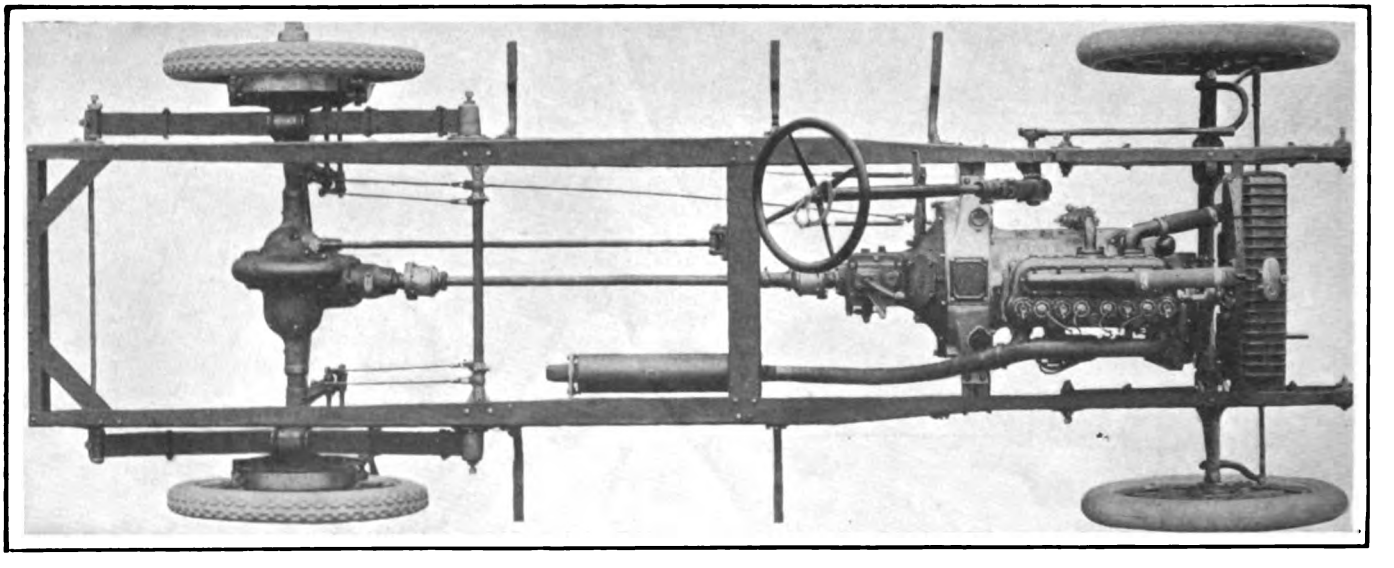
Right side of Continental 3 by 5 in. motor used in the new Commerce delivery car

Motor Is Rugged Job

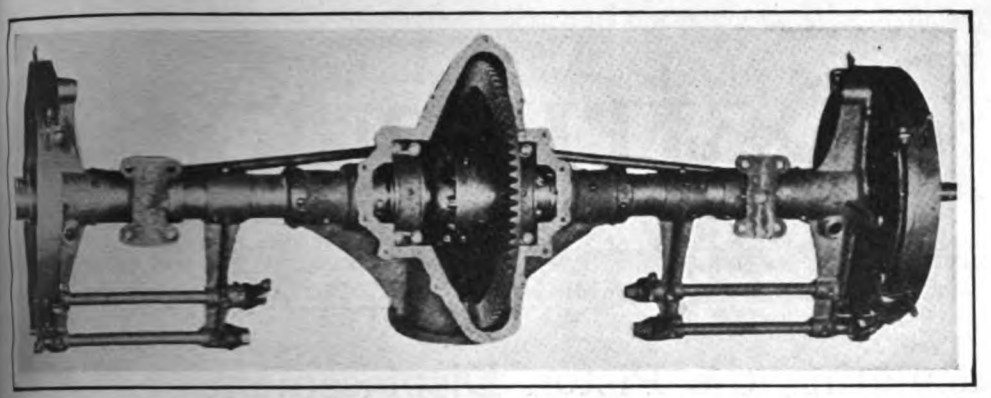
There is no need to say much about the motor save that it embodies all the best Continental practice. The four cylinders are in block and the valves are individually accessible through brass valve cups which makes grinding in a somewhat quicker job than when the whole cylinder head has to come off. On the right side the Eisemann magneto is situated and is low enough not to obscure the valve springs which are inclosed behind pressed steel cover plates. On the left side there is nothing but the Breeze carbureter and the oil filler.

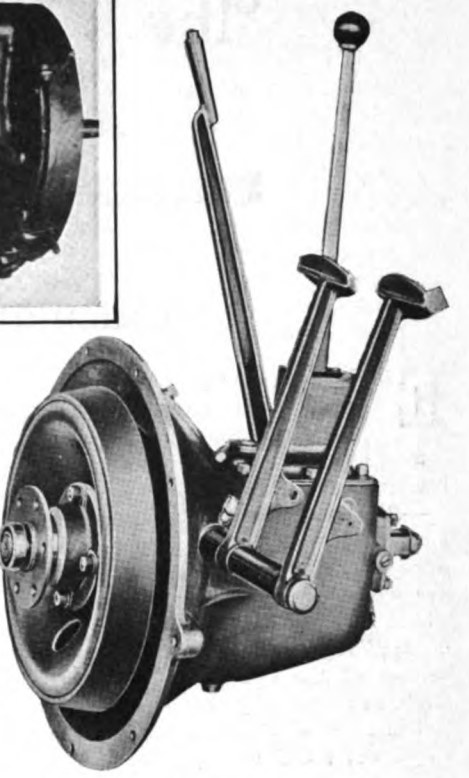
There are three large crankshaft bearings to which oil is fed under pressure from the plunger pump that is operated off the camshaft, dip troughs catching the overflow and caring for the connecting rod lubrication. A separate feed supplies the helical front end gearing. On the left side just alongside the oil filler is a gage with a dial that shows at a glance whether there be the proper supply in the oil pan.

In order to save weight the engine has an aluminum crankcase, but the gearset is housed in cast iron as the case is



Plan view of Commerce delivery car chassis, showing the strong construction of the assembled units and three-point suspension of the power plant





Upper left—Showing the strong construction of the rear axle used in Commerce delivery cars. Note the large braking surface

Right—Clutch and control lever assembly on the new Commerce. Note compactness of the unit

small. The leather cone clutch makes up with the gearbox and has a self-contained thrust as is shown in the drawing. Of course the gears are a very important part of any commercial car since they come into use so much more frequently and this gearset has been constructed to withstand any amount of hard usage. It may be noticed that the bearings are all large, especially the double row New Departure at the rear end of the main shaft.

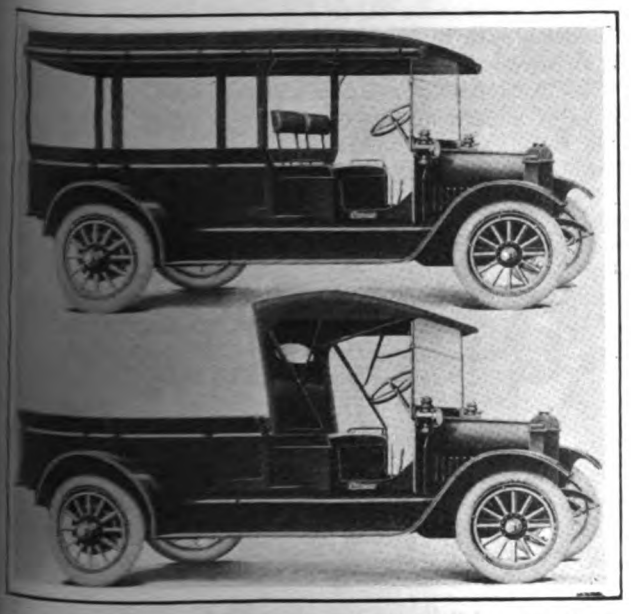
Three-Point Suspension

Three-point suspension is used for the power plant, the front end resting on a dropped cross member of the frame. It should be noticed in the chassis plan that this cross member does not carry the radiator and the reason for this is interesting. It is certain that the frame of any car of this sort will weave, so the radiator has a stiff cross member with nothing to do save support the water carrier. This cross member is not riveted or bolted rigidly to the frame sides, but is secured by only two cap screws that are put through the upper flange of the main frame, one on either side. Any weave that takes place in the main frame cannot by any possibility, twist the radiator support, so the cooler is relieved of all stresses.

For the radiator cast iron top and bottom tanks are employed and the middle part consists of a nest of vertical tubes. The side pieces are plain pressed steel and contain no water. Thus should the radiator happen to be damaged it is easy to take out and replace the middle part without having to buy a complete new radiator. There is a large hinged filler cap through which water can be poured from a bucket without the least difficulty.

Coming now to the axles, the rear is a built-up construction with a stout cast steel center that carries the differential and bevel wheels, there are four differential pinions and large ball bearings to support the whole. As a type the axle is three-quarter floating, with Hyatt heavy duty bearings to carry the wheels. Brakes are 15 in. diameter and 2 in. wide so there is plenty of surface.

A point to be observed is that the Commerce company has abandoned the single universal joint construction in favor of two universals with a torque stay. The front axle is a heavy I beam section with nothing special about it, but the springs are quite a feature. Those at the rear are 50 in. long and no less than 3 in. wide while the front springs are 36 in. by 2¼ in. All shackles are bushed with bronze, and the rear end hanger which has a great deal of work to do has a large grease pocket which cares for the lubrication in the event of the driver neglecting his grease cups for a few days. In laying out the brakes the countershaft has been located on the line between the two front end hangers, so that movement of the axle does not affect the brakes.



Two of the Commerce models for 1916. They have a capacity of 1,500 lb. and are made in various body styles

Three Body Types

There are three standard body styles, a panel car, an express truck without canopy and with a mohair top for the driver, and an express car with wood top. All three complete vehicles cost the same $975. The thoroughness of the chassis work is equally apparent in the bodies. Of course it is not hard to make an open body strong enough, but a panel body that will not rattle or bulge after a year's hard service is a different sort of proposition. For the Commerce panel body plenty of good hardwood framing is used, the doors are solid enough for a 3-ton truck and the hinges and bolts so stout that the roughest sort of treatment could not hurt them.

Further all three bodies are well finished and carry their ruggedness in their appearance.

Standard tire equipment consists of United States pneumatics 34 by 4 in., non-skid on the rear wheels and plain in front, while one spare rim is included in the equipment. The windshield is in keeping with the rest of the fittings and the oil lamps are heavy gage material.

The Rostrum

Calculating the Piston Displacement

EDITOR THE AUTOMOBILE:—Will you please explain exactly how to find the piston displacement of a motor in cubic inches?

2—Has the r. p. m. anything to do with the calculation?

Irving, N. Y. E. C. H.

—Piston displacement of the motor means the volume passed through by the pistons during one stroke. In other words, for each cylinder it is the cubical contents of a cylinder whose diameter is equal to the bore of the motor and whose length is equal to the stroke of the piston. With this in mind it is only necessary to give the rule for finding the volume of the cylinder which is the area of the sectional circle multiplied by the length of the cylinder.

The area of the sectional circle is equal to the diameter (squared) multiplied by .7854 and thus the formula becomes:

$$D = .7854\, d^2\, L$$

In this formula D is the displacement; d is the diameter of the cylinder or the bore of the motor, and L is the length of the stroke. Thus, for a 4 by 5 motor of one cylinder, the displacement would be:

$$.7854 \times 4 \times 4 \times 5$$

and for a four-cylinder motor it would be:

$$.7854 \times 4 \times 4 \times 5 \times 4 = 251.3$$

2—The r.p.m. have nothing to do with calculating the displacement unless you desire to bring in the factor of time. If you wish to know the displacement of a motor per minute, then you would bring in the factor of r.p.m. When speaking of the piston displacement of a motor, the r.p.m. have nothing whatever to do with the matter.

Very often it is desired to estimate the volume of gas entering the cylinder in a given time and when this is done the displacement for a given time is calculated. For instance, if it is desired to know how much gas is drawn into a motor for a period of a minute, it would be necessary to know the number of intake strokes per minute and multiply this by the piston displacement. This would give the theoretical amount of gas drawn into the motor, but as a matter of fact, since the volumetric efficiency of a motor is never 100 per cent, only a portion of this amount of gas would be drawn in. It is only with theoretical calculations of this nature that the displacement for a given length of time is used.

Wants to Increase Speed of Regal N

Editor THE AUTOMOBILE:—I would like to ask you for your advice on a few matters relating to my car, which, being of American manufacture, is difficult to obtain in England. I want to increase the road speed of this car and any help you can give me will be greatly appreciated.

1—I own a 1913 Regal model N, underslung car number 5085, and I am desirous of increasing the speed at the road wheels. How can I best obtain this—by either fitting a new ring gear and bevel pinion of higher gear ratio, lighter reciprocating parts to engine, or larger road wheels? The best speed obtainable at present is 35 m.p.h., but at anything over 30 m.p.h. the vibration is excessive.

2—Regarding the water circulation, the engine is cooled by what is known as thermo-gravity circulation, wrongly called thermo-syphon, but it could not very well be worse, the water does not circulate. Could not a circulating pump be fitted? If so, how and where? Would like the approximate cost of parts recommended.

3—Regarding the underslung frame, is there any real merit in this type of frame? If so, why do not more makers use it? Also, is it a part which the Regal company has discontinued using?

4—I get a slight leak from the bottom of the Model L Schebler carbureter. How can I prevent this? The cork float is good and the valves appear tight.

5—Can the rake of the steering column be altered?

Paignton, England. F. W. G.

—You can probably increase the speed of the car considerably by doing all the things which you suggest. The expense will be considerable, however, and possibly it would be better to rely simply upon a higher gear ratio and a change in the timing so as to put the spark further ahead for high speeds.

2—THE AUTOMOBILE has no record of what it has cost for previous installations of water pumps on cars in which the original cooling system was of the thermo-syphon design. The pump installation will be also a rather complicated matter on a car which has not been built for it, and it is impossible to estimate accurately what the cost will be for arranging the drive, etc. The work in fact, could not be attempted except by a shop where the equipment is complete and where those in charge of the work are mechanics of exceptional ability.

3—The Regal company has abandoned the underslung frame and so have other American manufacturers who at one time used it. The fact that it has fallen into disuse is sufficient to show there has been no real demand for it.

4—The repair of the leak will depend upon whether or not it is of a permanent nature of merely the condensation of the gasoline in the manifold after stopping the motor. If the gasoline leaks from the carbureter for a short time after

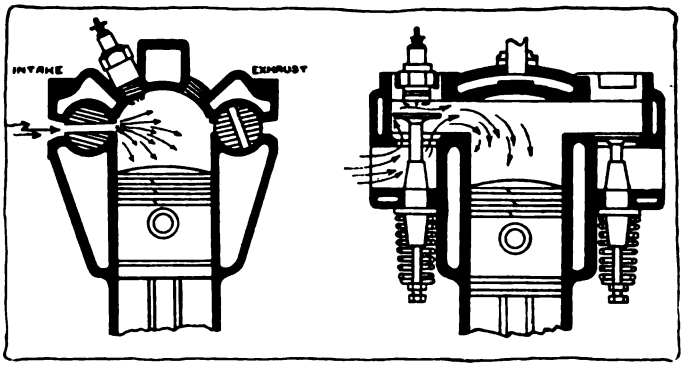


Fig. 1—One of the advantages claimed for the rotary valve motor is the direct flow of the intake gas

the motor is stopped, and then stops leaking, it is the gasoline which has been drawn up in the manifold condensing and then running back into the carbureter, causing it to overflow. The remedy for this is in the fitting of hot air connections which assist in thoroughly vaporizing all the gasoline. If the leak is a steady one it shows that the cork float is slightly water-logged, in which case it will have to be dried out and re-shellacked or the valve to the gasoline inlet does not seat tightly and will have to be ground in.

It would be advisable to make sure that the float valve seat and that the bowl gasket in the bottom of the bowl are in good condition with the float at the proper height, that is 1 1/16 in. from the top of the bowl to the top of the float. If these three points are correct, the carbureter will not leak.

5—The rake of the steering column can be altered by simply loosening the bolts which clamp the steering gear to the sub-frame and pulling the column down to the desired angle and then tightening the bolts again.

Interested in Rotary Valve Motors

Editor THE AUTOMOBILE:—I am interested in rotary valve motors and wish to learn the action and design of the Speedwell, Mead and any other well known design.

Do these motors cool the valve core or shaft by forcing water into them or simply cool by water-jacketing the container? If water is passed into the core, how is the connection made with the water pipe? How large a port area in square inches do these motors use to a certain cylinder size?

Fairfax, Mo. A. L. C.

—The Speedwell and Mead rotary valve are one and the same thing because the Mead rotary valve motor is used in the Speedwell car. The manner in which this motor operates cannot be better described than in the accompanying diagram, which shows the valve in various positions for a four-stroke cycle motor. As seen by the diagram, Fig. 2, the Mead rotary valve motor employs two rotating sleeves, one for intake and the other for exhaust, thus giving a sort of T-head construction, although the advantages of semicircular sections are maintained by the combustion chamber. In practice, the intake and exhaust rotating sleeves are made in halves, this being done so that longitudinal expansion of the rotating sleeve can be taken care of at the joint. For a six-cylinder motor one-half of the intake valve would serve three of the six cylinders and the other half coupled to it would serve the other three cylinders. The intake and exhaust valves are similar in appearance. The path of the gases through these sleeves is shown in Fig. 1. The method of drive for the valve can be anything desired, a common means being a worm mounted on a vertical shaft which drives the two valves which are directly connected to worm gears which mesh with the worm on the vertical shaft. Regarding your question as to the water-jacketing and cooling used in connection with these motors, the illustration of the castings employed in actual manufacture will clearly bring this out. The container of the valve is waterjacketed but the valve itself does not hold any water because to do so would mean a very complicated arrangement, since there would have to be some connection between the moving valve and the stationary part. The port areas in these motors are very close to the areas of the clear openings of large poppet valves, the gain being not so much in valve size as in valve timing.

Has Trouble with Overheating

Editor THE AUTOMOBILE:—I have a 1912 model B Abbott-Detroit. For the past two years this car has been heating, and several people have tried to remedy this fault without success. It is heating worse than ever now, and I would like to know what I can do. The entire system has been flushed throughout, radiator, cylinders, every pipe and water connection has been cleaned, carbon removed from cylinders, valves, pistons, etc. The spark has been advanced to the farthest possible position, the gas mixture cut as lean as possible, and the fan works all right. The oiling system has been thoroughly gone over and every part of the motor seems well lubricated.

Can you explain which way the paddle wheel in the water pump should go? It seems as though this wheel has been changed and I have put it on the way I am almost positive it should go, despite opposition, and I now leave it to you.

2—Will the placing of a heavy gasket between the cylinder blocks and crankcase, to lower compression, have any effect upon the cooling? This I notice has been done at some time.

New Smyrna, Fla. I. A. M.

—It would seem as if you had done about everything possible to overcome the heating in the Abbott motor, unless the water pump paddle which you mention has been placed in the pump casing wrong end to. The casing of the water pump on the model B Abbott consists of two parts, known as the body and the cover. The body is the larger half, while the cover is the smaller half. The body has the inlet connection to the cylinders, while the cover has the connection which draws the water from the radiator.

The body is the half which is closest to the front of the car and the paddle has one side entirely smooth with the exception of the hole for the pump shaft, while the other side has part of its surface cut away around the pump shaft hole to admit the passage of the water. Obviously, the paddle must go into the water pump body smooth end first, as if it is placed the other way around it would shut off the passage of the water, preventing it from reaching the pump, and hence the circulation would cease.

It can be readily determined whether or not the paddle has been placed in properly by merely taking off the radiator cap. When this is done and the motor is running the water can be seen circulating in the radiator when the paddle has been placed in properly and the pump is working.

2—The heavy gasket you mention as having been placed between the cylinder blocks and the crankcase was originally

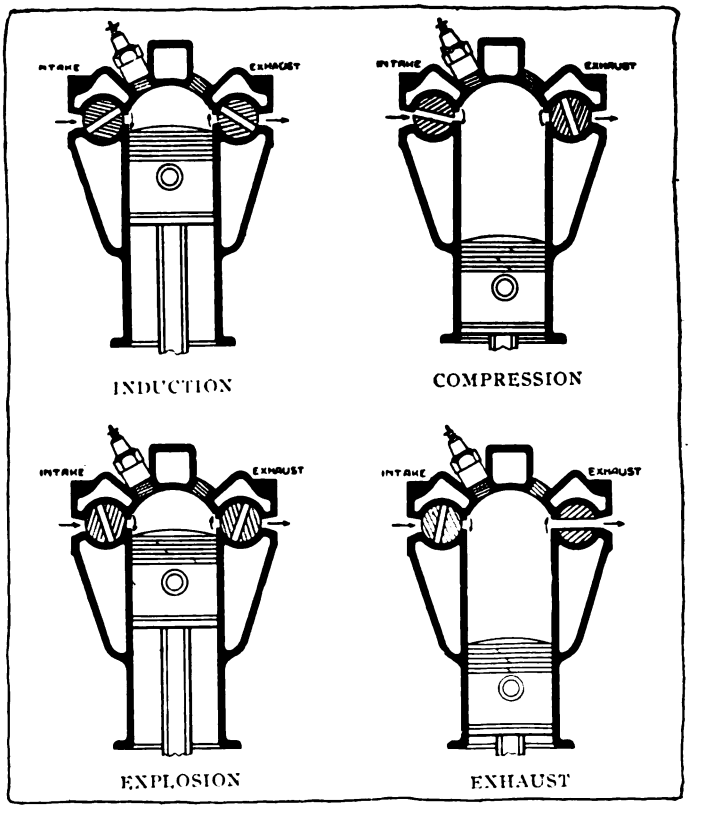

Fig. 2—Mead rotary valve as used on the Speedwell motor in different phases of its four-stroke cycle

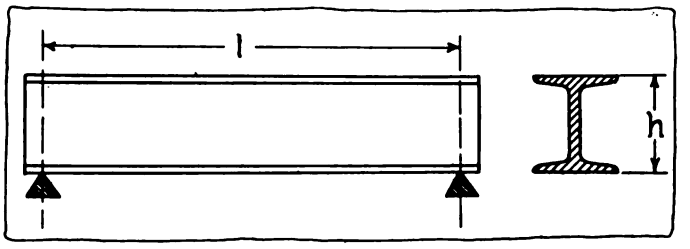

Fig. 3—Diagram of I-beam supported at ends, 1, is the length or span of the beam and h is its depth

put on the car at the factory, and this will not in any way affect the cooling system of the motor. If the trouble is not in the water pump paddle the only suggestions which apply are those which would be true with any gasoline engine having a water cooling system.

Causes for Jumping at 15 m.p.h.

Editor THE AUTOMOBILE:—My Ford 1915 model is inclined to jump or run unevenly when running at from 12 to 15 miles, but works satisfactorily when warmed up and at higher speed. The ignition, gasoline line and valves are in good order.

2—Can you advise me where I can obtain a float for a Holley carbureter?

Dresden, O. J. S. C.

—Without seeing the car it is very difficult to say what may cause a thing of this kind. In fact, the action of the car itself and the "feel" to the driver are largely what determine the points to be looked after in remedying the trouble. If the car goes along well and then suddenly acts as if the brakes have been put on, due to the fact that the motor misses fire or explodes unevenly and has to work against the compression of the dead cylinders, it is an entirely different feeling from that due to first weak and then strong explosion. Sometimes a slipping clutch will cause an uneven sensation.

It is possible that the commutator is dirty or that the valves are in such condition that they seat tightly enough for higher speeds, but at low speed permit a leakage of gas and hence they miss. Some of the units or contact points on the coil vibrators might be badly worn or dirty and need cleaning and adjustment. Sometimes the misadjustment in these coils is just enough to be noticed at certain speeds. At other times, a short circuit in the ignition may give an irregular action and this can be quite often detected by the buzzing of the coil unit continuously instead of intermittently. Some of the reasons generally given for the engine running irregularly at low speeds are the following:

1—Close gap between spark plug points.
2—Too great clearance between valve stem and pushrod.
3—Weak exhaust valve spring.
4—Air leak in intake manifold.
5—Coil vibrator improperly adjusted.
6—Spark plugs dirty.
7—Gas mixture too rich or too lean.
8—Poor compression on account of leaky valves.

Only Experts Drive in Big Races

Editor THE AUTOMOBILE:—Are only expert drivers allowed to race in the big events like Indianapolis, Chicago, Vanderbilt Cup, etc.?

2—What is necessary to become a professional driver?

3—What firms employ amateurs so they can acquire experience?

Newark, N. J. G. H. MESSER.

—Only expert drivers are allowed to race in events of this class.

2—To become a professional driver it is necessary to have the owner of some car designate you as the pilot of his vehicle and permit you to enter it in the contests. Generally before a man employs a driver he must become convinced of his ability, and, therefore, it is generally necessary to have some kind of work or practice which will enable you to prove that you are capable of handling high-speed racing cars.

3—No firms employ amateurs for the purpose of giving them experience in racing.

Kleinart Is Reconstructed King Racing Car

Editor THE AUTOMOBILE:—Is Klein's Kleinart the King racer reconstructed, or is it a new car?

2—What are the racing colors of the Maxwell and Sun beam companies?

3—Has kerosene been used in the Maxwell racers since the 1914, 500-mile race?

Rye, N. Y. G. MCCULLOH.

—Klein's Kleinart is the King racer of last year entirely reconstructed. The wheelbase is now 108 in. whereas it was formerly 113 and the motor is now under the 300-in. displacement limit, having a Duesenberg motor, eight-valve, 3 63/64 by 6 in. bore and stroke.

2—As far as is known to THE AUTOMOBILE these teams have no definite colors. Some of the Maxwell cars have been distinguished by the use of American shields. As far as THE AUTOMOBILE has any record kerosene has not been used in any of the large races this year.

Building Garage Over a Creek

Editor THE AUTOMOBILE:—I am building a new garage which will reach over a creek and concerning the construction would like to ask the following questions:

I will have a span of 22 ft. across the creek and intend to use an I-beam suspension with an I-beam 12 in. deep, 5.21-in. flange and thickness of web 0.56 in. having a sectional area of 11.76 sq. in. How much load will one of these carry in the center supported at the ends only?

2—How many would you recommend for a span 22 by 8 ft., using 2 by 12-in. wooden joists set into channel of the beam on each side to lay the floor and being placed 16 in. center to center?

Crestline, O. O. F. F.

—The formula by which beams supported as you state are calculated is: $M = \frac{SI}{c}$ in which M is the bending moment, S is the unit stress on the part of the beam furthest from the neutral axis which is the center line in the case of an I-beam, c is the distance of the most remote fiber from the neutral axis which in the case of an I-beam is equal to one-half the depth and I is the moment of inertia. The part of the formula $\frac{I}{c}$ is known as the section modulus and for an I-beam this is equal to $\frac{Ah}{3.2}$ where A is the area of the flange section and h is the depth of the beam.

Substituting for the section modulus the dimensions given by you the value 44.1 is secured.

The formula for the bending moment for your beam therefore comes: $M = 44.1\ S$. If the beam is to be loaded at the center the bending moment is equal to half the load on the beam times half the span. As the beam is 22 ft. long the bending moment at the center for a load of P (lb.) would be $\frac{P}{4} \times 11$ and assuming the tensile stress to be equal to 16,000 lb. to allow plenty of factor of safety if the beam is of steel and 14,000 lb. per square inch if the beam is of iron, the equation would become:

$$5.5\ P = 44.1 \times 16{,}000 \text{ or } 44.1 \times 14{,}000,$$

or the safe load would be about 12,800 lb. on a steel beam and 11,200 lb. for an iron beam.

The calculations given above are assuming that the

is all concentrated at the center, but if the beam is uniformly loaded from one end to the other, as it probably would be in the way the building would be constructed, the safe load on this beam would be double that given for the load concentrated at the center. The figures given for safe load on steel and iron beams are those furnished by the Pencoyd Iron Works, Philadelphia, Pa.

2—This would depend on the floor load.

Motor of 2388.8 Piston Displacement

Editor THE AUTOMOBILE:—Kindly give me the S. A. E. rating and piston displacement of an eight-cylinder motor, the bore and stroke being 6½ by 9.

2—Is the magneto on a Reo six a high or low-tension?

3—What is the highest automobile license in Ohio?

Akron, Ohio. G. H.

—The S. A. E. rating of an eight-cylinder motor, 6½ by 9, is 67.6 hp. The piston displacement is 2388.8 cu. in.

2—The magneto on the Reo six is a Remy high tension.

3—According to our latest advices on Aug. 2, Ohio had 161,700 motor cars registered since the first of the year and estimates at that time were made that by the end of the year 175,000 cars would be registered. At that date the chauffeurs' licenses numbered 13,643.

Van Sicklen Uses Air Principle

Editor THE AUTOMOBILE:—Will you please explain what the "air principle" in speedometers is?

2—What is the construction of the Van Sicklen speedometer?

Lowell, Mass. J. C. C.

—The air principle, when referred to in connection with speedometers, generally deals with the method used by the Van Sicklen apparatus made by the Van Sicklen Co., Aurora, Ill. This speedometer differs from others in general use in that its operation is based upon the generator and calibration of a current of air. This air current is generated by a spiral gear pump which is driven in the conventional manner by a flexible shaft from one of the road wheels or from some portion of the transmission mechanism.

The illustrations, Fig. 4, show the construction of the instrument. The current of air generated is directed against a vein on the inside of the floating dial. The floating dial itself is a light inverted cup secured to a shaft that passes vertically through its center as shown in the illustration. The shaft forms an axis about which the cup is free to turn, and when the air current generated by the pump is directed against the vein on the inside of the cup, it tends to turn it on its axis.

Referring to the illustration of the floating dial, it will be noted that the mileage scale and figures are placed on the outer vertical face of the inverted cup and these graduations are visible to the driver. As the speed of the car increases, the speed of the little pump increases proportionately, as does the air pressure against the vein of the floating dial, but in order to regulate and calibrate the effect of the air pressure upon the dial, a channel is provided beneath the vein through which the air is allowed to escape. This channel is graduated in width so that the relation between the amount of air directed against the vein by the pump, and the amount allowed to escape under the vein is so balanced or proportioned as to hold the vein in such a position that the scale showing through the face of the dial indicates the speed.

For example, at 5 m.p.h., the pump is creating a draft of air against the vein, the force of which is so regulated by the width of the channel beneath it, though a certain proportion of the air escapes, that the Fig. 5 on the floating dial registers with the point in the center of the opening on the face of the instrument. In a like manner at 10 m.p.h., a greater draft is being directed against the vein of the floating dial by the pump, having a tendency to force it further around on its axis, and therefore the distance to which the dial or vein is turned is simply limited by the channel beneath the vein which governs the amount of air allowed to escape. A spiral spring is provided as shown at the top of the floating dial which tends to bring the dial back to zero and the air passage is so arranged that the resistance of this spring is compensated for.

2—The construction of the Van Sicklen speedometer is that shown in Fig. 4, and the principle of operation is that above described. This is what is known and referred to by the Van Sicklen company as the air principle.

Timing of Abbott-Detroit Four

Editor THE AUTOMOBILE:—What is the proper timing of the valves in the Abbott-Detroit?

From the sound of the exhaust, which emitted a half burned mixture, I decided that the valves were out of time so I changed the position of the camshaft two teeth, with the following results: More power, less fuel consumption, but with a greater tendency to heat.

2—What is the proper size of nozzle for the model 30, using the Stromberg carbureter?

New Smyrna, Fla. J. A. M.

—The timing of the Abbott four is such that the inlet opens at 11 deg. past top center, and closes 44 deg. past bottom center. The exhaust opens 45 deg. before bottom center and closes 11 deg. after top center. If you will arrange the camshaft so that the inlet on No. 1 cylinder starts to open at 11 deg. past top center, all the other timings will automatically take care of themselves, since with a unit camshaft such as employed in this motor, when one point is fixed, the timing is automatically taken care of.

2—The proper size nozzle to use on this car is No. 63.

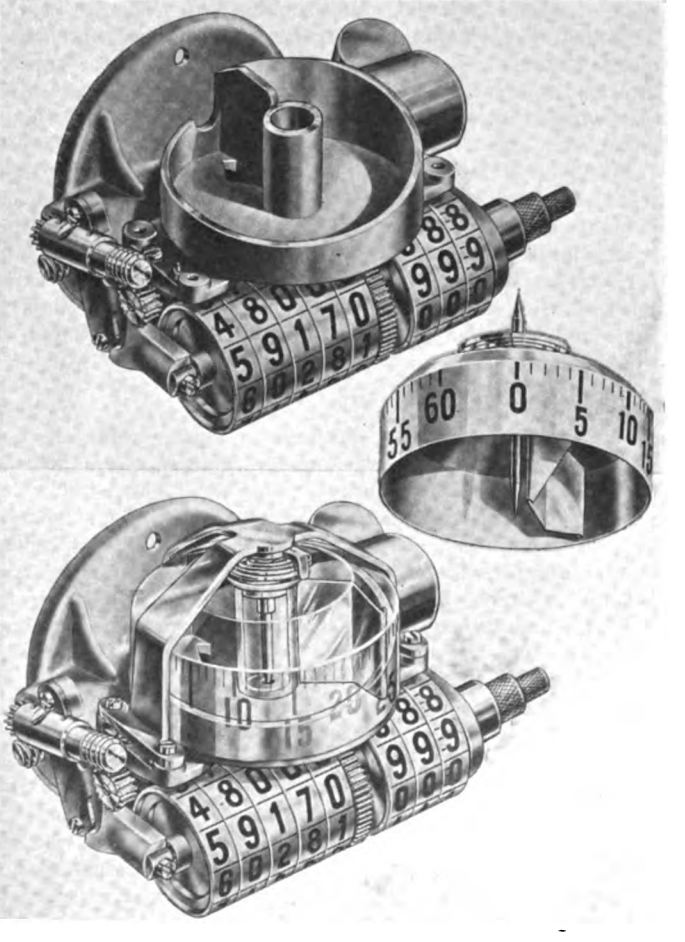

Fig. 4—Assembly views of the Van Sicklen speedometer, showing utilization of the so-called air principle

Car and Carbureter Design Suitable for Driving With Any Fuel

With a Study of Modern Carbureters Functioning with Automatic Brake Action on Fuel Feed at High Speed by Admission of Air in the Jet

WHAT is asked of cars in Germany under the present conditions of war and shortage of gasoline, with regard to their suitability for being operated with any fuel that can be obtained, throws a strong light on the requirements with which all cars may eventually be expected to comply in other countries, including even the United States, with a view to economy in motor operation and the establishment of a wholesome competition in the motor fuel market. A direct and immediate technical and practical interest also crops out, bearing upon the best carbureter construction in general and the use of 30-speed (1800 r.p.m.) and 40-speed (2400 r.p.m.) motors with heavy fuels for stationary and boat work as well as for motor vehicles.

Moreover, American manufacturers building cars and trucks for export are necessarily interested in those developments in the motor fuels which must influence the design of motors and carbureters, making for long stroke, high compression, small sizes and high speed in order to burn benzol and alcohol and even heavier fuels on an equality and optionally with gasoline.

The treatment which Baron von Löw has given this subject in his *Brennstoffmischungen, Anlassbehälter und Moderne Vergaser für den Automobilbetrieb* (Fuel Mixtures, Auxiliary Fuel Tanks and Modern Carbureters for Automobile Traffic), published by Kreidel, Wiesbaden, supplements in many ways the work by Dr. Dieterich rendered in abbreviated form in THE AUTOMOBILE of July 29 and Aug. 5 under the title: Analysis and Valuation of Motor Fuels and 14 Methods of Examining Them. Von Löw presents an extract of his book in *Automobil-Rundschau* for June, and this is rendered in substance in the following. The presentation is throughout based on experiments he has made to arrive at a construction usable without changes with different fuels. His reasoning and conclusions agree, it will be noticed, with some of the recent developments of the fuel feed system in this country.

The Merits of Auxiliary Tanks

We need in reality two different fuels to operate our cars sensibly, one for starting the motor from cold and another to utilize it to best advantage when hot. The fuels which can be used for both conditions are uneconomical, as long ago realized in the case of stationary motors. Naphthalene motors, for example, are operated with benzol until hot and are then switched to their cheaper main fuel.

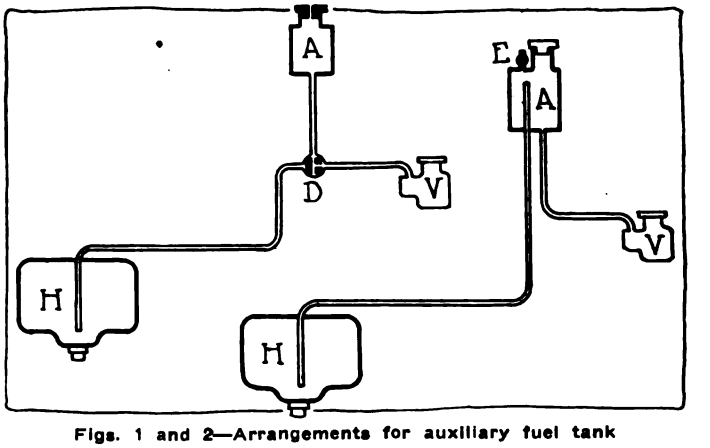
Figs. 1 and 2 illustrate two ways of arranging the auxiliary tank. H is the main fuel tank, A the auxiliary tank and V the carbureter. With the three-way cock D placed as in Fig. 1, the starting fuel flows to the carbureter and the motor can readily be cranked. After running for 1 to 5 minutes the motor is hot enough for the main fuel, and D can be turned on to admit it. An auxiliary tank on this plan facilitates measurements of fuel consumption and has the special merit for war conditions that it permits the car to be run 5 to 20 kilometers farther after the main tank has been put out of action by a shot. It is at least as good in this respect as a bullet-proof shield for the main tank.

Formerly auxiliary tanks were placed as in Fig. 2, with the object to avoid pumping pressure into the main tank after the motor has been stopped for some time. By admitting air through cock E the fuel then flows nevertheless at once to the carbureter and the motor can be started, whereafter the exhaust gases soon produce the necessary pressure in the main tank. For cars with an auxiliary tank a hand air pump is thus unnecessary and it is used only as a reserve for the case of certain troubles. But the older form of auxiliary tank, Fig. 2, is not adapted for present purposes—starting with a special fuel—since the fuel from the main tank flows through it and remains there after the motor has been stopped.

The Heating of the Liquid Fuel

The starting fuels which may be considered are benzol, gasoline and ether, and the main fuels are mixtures of benzol with alcohol, heavy petroleum and tar oils and also unmixed alcohol and the products of the cokeries using coal or lignite for raw materials. In order to use the heavier ones among these fuels it is necessary, besides using an auxiliary tank, to develop the heating of the carbureter more systematically than is usually done in automobile motors. Fig. 3 illustrates several possibilities in this respect.

The simplest means for improving the heating consists in using lead gaskets instead of asbestos at the joints of the induction pipe, P, P and bb. At the same time metal gauze can be laid across these joints, so as to heat the mixture not



Figs. 1 and 2—Arrangements for auxiliary fuel tank

only along the walls of the duct but all the way through it. The same object is served by piercing the suction channel with a hot-water pipe from the water jackets, as indicated at RR. These two provisions—the metal gauze and the pipe through the suction channel—involve a considerable reduction of the cross-section area of the channel and are therefore not usually recommendable, but in other places, such as the three marked *ss*, where they do not reduce the necessary area (the pipes being flared to offset the reduction) gauze screens are desirable for fire security.

Although in general the heating of the liquid fuel is much more advisable than the heating of the mixture, it has not been found a good plan to carry the fuel pipe in two or three coils around the exhaust manifold, as this heats a volatile fuel too much. For the fuels used in the experiments it was

sufficient to heat the carbureter by drawing exhaust gas from a sleeve surrounding the exhaust pipe and wound with asbestos cord. By providing the suction channel with a flop K it was made possible to draw cold air as well, when required. Fig. 3 shows further the two cocks HH with the aid of which an additional dosing with air can be provided for a fuel that requires it.

With a wrapped suction channel and an auxiliary tank as the only additions made to the normal car equipment and a few shims in reserve for loading down the carbureter float, the tests with the heaviest fuels were begun, the nozzles and the air intake areas remaining unchanged as used for operation with gasoline.

That a good carbureter can work with benzol—without extra loading of the float—equally as well as with gasoline—is a fact now widely known, but it was surprising that the car with the arrangements mentioned also ran pretty well with kerosene. To be sure, in previous experiments with an old car and an old spray carbureter, both of 1906 model, it had been shown that this old carbureter could work without any re-adjustment with ordinary alcohol and kerosene, but the motor speed at those tests had to be so high that normal operation of the automobile was impossible. With the new car and the new carbureter, both from 1914, the situation was quite different. Even at low motor speed the heavy fuel was here so well atomized that an explosive mixture was formed and the motor worked. On the other hand, high motor speed became precarious with kerosene for fuel. The throttle had to be partly shut to avoid knocking. It is well known that kerosene motors must have a larger combustion chamber than gasoline motors because a kerosene mixture gas is more easily fired by compression than a gasoline gas mixture, and therefore liable to premature ignition. That the throttle could not be opened interfered of course considerably with the utilization of the car with kerosene; it could only be driven at 40 kilometers per hour on level roads with the high gear in mesh while it should have reached 80 kilometers.

Mixtures of kerosene and benzol in equal parts gave much better results, but for lack of kerosene these tests were not continued. Mixtures of benzol and alcohol were taken up instead. Starting onto a measured stretch of road at 40 kilometers per hour and pushing the motor to its best it was observed what maximum speed was reached at a point further on, B, where a slight downward grade changed into a sharp upgrade, and also to what point the speed had dropped at C, at the top of the rise. Pure benzol gave 82 kilometers per hour at B and 56 at C, while a mixture of 1 part benzol and 2 parts alcohol gave 78 kilometers at B and 48 at C.

On another stretch of road where B lay somewhat higher than the starting point and C at the top of a sharp rise as before, pure benzol gave 65 kilometers at B and 62 at C, while the mixture gave respectively 62 and 56 kilometers and another mixture composed of benzol and alcohol in equal parts gave 64 and 60, or almost as good a result as the benzol alone.

[The author here goes on to show that a given volume and a given money value of the mixed fuels give more mileage than the same volume and value of gasoline and slightly more mileage than the same money value of pure benzol, but the comparisons are mainly of interest for the war conditions under which the price of gasoline has gone up more than that of benzol and the latter more than that of alcohol. He shows finally that, in order to make gasoline, benzol and alcohol equally economical, the prices per liter should be 42 pfennig for benzol, 35 for gasoline and 32.4 for alcohol, these figures holding strictly good only for such a car as was used by the author—with auxiliary tank and wrapped exhaust pipe sleeve and suction channel—while subject to some modifications for other cars originally less well adapted for being operated with benzol and alcohol.]

To illustrate, further, the possibilities for using different

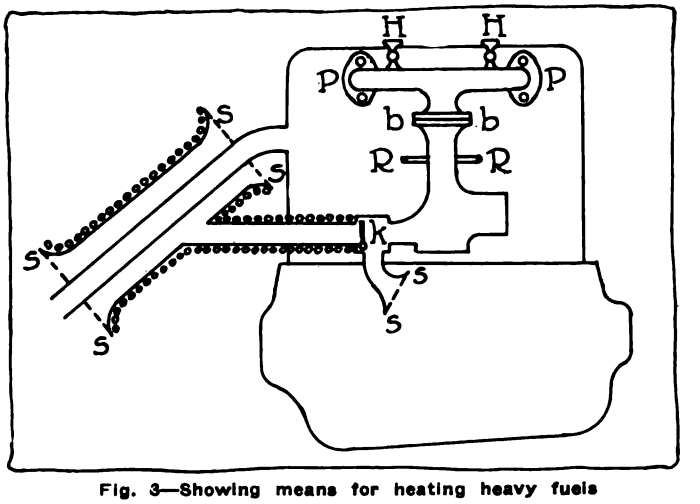


Fig. 3—Showing means for heating heavy fuels

fuels the author's practical experience supplies data of interest. For the past three years he has driven his cars mainly on benzol, and nothing was changed in the cars. Nozzles and jets, float levels and heating arrangements remained as they were, and yet the cars work better with benzol than with gasoline. When occasionally it was impossible to obtain benzol he was compelled to drive for a couple of days on gasoline, and in those cases there was always noticed a lessened ability to pull through on any given gearspeed, and knocking of the motor occurred easily—something which never happens with benzol. Similar observations were made with regard to cars driven by others. On the whole, he found that there were no drawbacks to the use of benzol for cars not of a decidedly antiquated construction; one of his own dating back, as mentioned, to 1906 and being used entirely without changes.

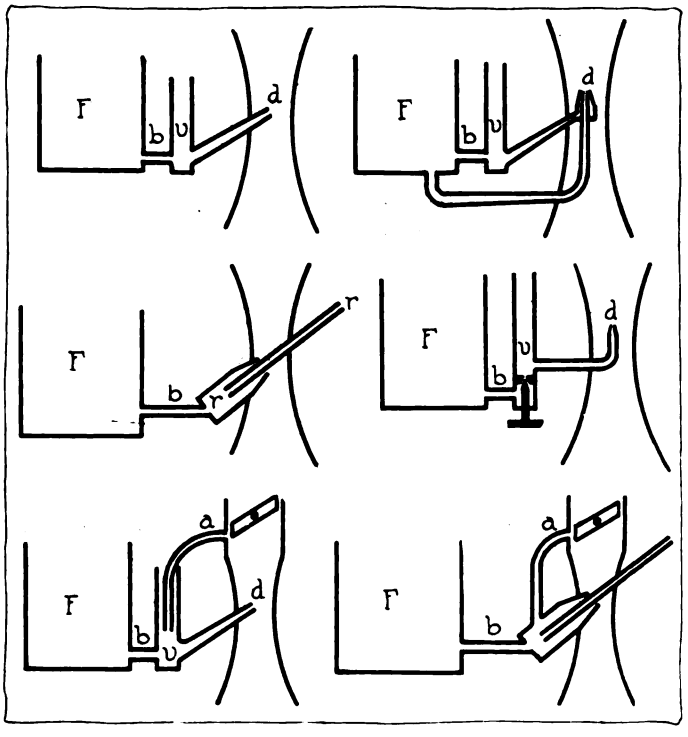
The much feared soot formation so often charged against benzol is in reality quite immaterial, as it occurs only during the first minutes after starting, and later, when the motor gets warm, the soot is gradually burnt out. The film of soot reaches therefore only a certain thickness, and it is rather harmful than useful to clean the spark plugs and piston heads frequently.

More astonishing than the fact that the modern motors work equally well with gasoline and benzol is the observation that they accomplish almost as good results with alcohol as well. This seems singular, since the caloric value of alcohol is so low and the attempt made 12 years ago to run the Berlin taxicabs on alcohol proved a failure. The answer is the following: The low caloric value of the alcohol is in part compensated by the related fact that alcohol requires much less air for its combustion than either gasoline or benzol, so that a cylinderful of explosive alcohol mixture after all contains nearly the same amount of energy as a cylinderful of the other explosive mixtures. And the early failures were due to the design of early automobile motors which had lower compression and shorter stroke than those of the present day.

The efforts made for improving the motors on general principles have incidentally and without intention resulted in meeting the requirements for employing benzol and alcohol as fuels.

The car with which the road test figures were obtained is the same Audi car with which director Horch of the Audi works took part in the 1914 Alpenfahrt (reliability run in the Alps). It has a motor with 90 millimeter bore and 140 millimeter stroke and weighs 1356 kilograms and is in the same condition in which it came back from the Alps, excepting the addition of the auxiliary tank and the stronger heating device.

If the figures obtained with this car are somewhat better than could ordinarily be obtained with vehicles of older date, other tests with two Horch cars of 1906 and 1908 and with



Figs. 4, 5, 6, 7, 8, 9—Diagrams of modern carbureters

two Mercedes cars of 1910 and 1912 have nevertheless shown that older cars with older carbureters can work very well with the new fuels. The mixtures of benzol with alcohol are especially to be recommended those who are nervous about the soot formation with pure benzol. By mixing the two fuels both the soot formation with benzol and the rust formation with alcohol alone are most effectually obviated.

Almost as harmless as the slight soot formation with benzol are the small explosions in the carbureter with alcohol. If the reports occur with a certain adjustment of the throttle, the best plan is to throttle down till they stop and then to open the throttle again by degrees, at each adjustment giving the motor time to get warmer. It will then in most cases work properly after coming back to the first adjustment. But if the driver gets fidgety and tries every two seconds if the explosions will occur when he opens up wide, the motor of course gets colder all the time and the explosions get more frequent. No doubt, the technics of motor construction are already so advanced that motors could be built now for all the fuels which on the whole would work more perfectly than the best automobile motors built for gasoline only.

Compression the Critical Feature

Among motorists catch phrases are very current. One of these has it that "the automobile motor is a gasoline motor," meaning to convey the idea that it is a risky thing to operate it with any other fuel than gasoline. But it is now an established fact—widely known and based on fundamental heat economics—that a good automobile motor works better with benzol and other fuels than with gasoline, and the phrase therefore holds true only for antiquated designs. There is general agreement on this point among motor engineers, and the author claims only the discovery that practical motor building is already much farther advanced than usually supposed and that results are obtained with the good automobile motors of to-day and modern carbureters which nobody had expected.

Another catch phrase says: "The fuel question is a question of carbureters." But this slogan is no more correct than the other. The fuel question is—like all important problems relating to internal combustion motors—a question of the compression. But a good carbureter can contribute to the solution of fuel problems.

[It was well understood as early as 1902 that alcohol motors should have a long stroke and a compression of 140 lb. In the modern European automobile motor the long stroke, the high piston speed made possible by improved balancing and better materials and workmanship, the large valves giving a full charge and the moderately high compression—made actual by the speed and the valve dimensions, while in 1902 it was theoretical only—have produced conditions for operating with mixtures of benzol and alcohol which really agree perfectly with the requirements formulated after the government tests with pure and mixed alcohol fuels conducted in France and Germany in 1901 and 1902. The statements made by von Löw are therefore not so radical or surprising as they may seem at first glance.—M. C. K.]

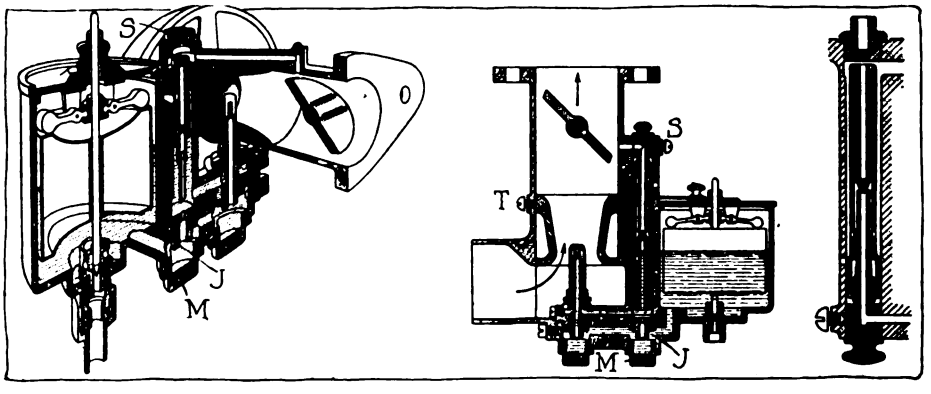
Spray Carbureters With Air Brake

Considering that the adoption of the principle of checking the fuel feed by admitting air to the interior of the jet (*Bremsdüsenprinzip*) stands for an improvement of carbureters which has only been accomplished during the past few years and contributes strongly to our ability to operate with different fuels, a review of the modern carbureters representing this type of design will be found in order to complete the presentation of the subject.

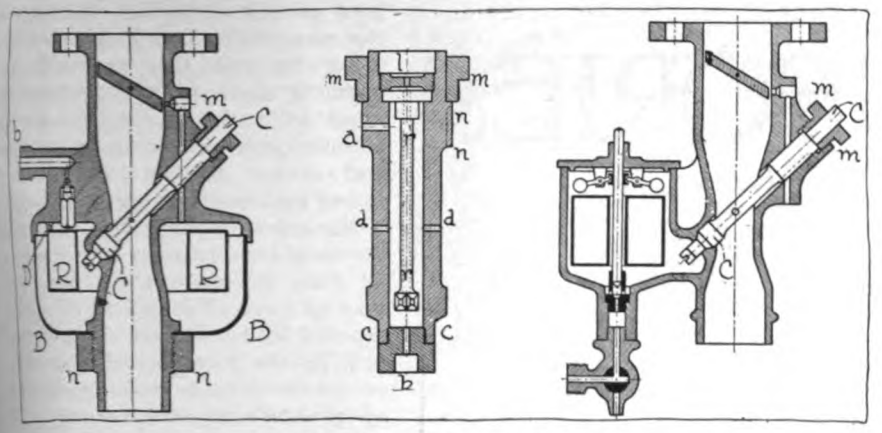
The principle is shown in Fig. 4. F is the float chamber, *b* the brake-jet, *v* a storage compartment and *d* the spray jet. When the opening of the throttle valve suddenly causes a strong suction, the fuel in the storage compartment serves for the acceleration, and when the motor has reached high speed the level of the stored fuel is reduced and air enters with it into the spray jet, while the brake jet *b* supplies fuel relatively slowly (due to the interference of the air). The Zenith carbureter has also another jet, as shown in Fig. 5, and in the Pallas carbureter, Fig. 6, the storage space is differently arranged and the brake air enters through the tube *rr*. A third carbureter, being the German Longuemare, is represented in Fig. 7. Here the brake jet is subject to regulation, while those in the Pallas and Zenith are easily exchanged. That these two carbureters also have a special starting jet *a* opening opposite to the edge of the throttle flop, on the plan indicated in Figs. 8 and 9, is a matter not concerning the main principle; similar starting jets are used in carbureters such as the Favorit, which have no brake jet arrangement.

Among 14 carbureters entered in the competition held in February, 1914, by the Prussian war department three were of the brake jet system, and they took the first three prizes.

Some of the details in the carbureters of this type illus-



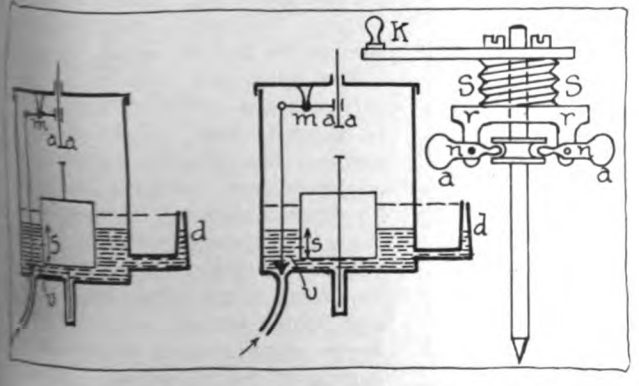
Figs. 10, 11, 12—Details of Zenith construction; horizontal and vertical



Figs. 13, 14, 15—Details of Pallas construction

trate the requirements in which motorists are interested. The Zenith, whose first appearance in the market led all carbureter technics into new paths of progress, is made in a horizontal model, Fig. 10, and a vertical model, Fig. 11. These illustrations show a number of narrow passages which are not readily accessible, and to remove jets and various screws special spanners are required. Both models have a special starting or still-running carbureter which can be taken out by removing or loosening the screws S. It is shown separately in Fig. 12. In the course of the years this auxiliary part has become more and more elaborate, due to the exaggerated demand for very slow still-running. The success accomplished in this respect is interesting, showing how patiently carbureters and motors can be made to behave. But in itself the capacity for slow still-running gives no guarantee of excellence in more important things, as there is a great difference in the carburetion requirements for slow-running without load and slow-running with full load.

The Pallas carbureter, Fig. 13, has the same admirable workmanship as the Zenith and can be taken apart without special tools. The jet mechanism *cc* can readily be taken out after removing the nut *mm*. Its details are shown in Fig. 14. At the upper end there is the air duct *l* from which air is led through the tube *rr*, referred to before in the diagram, to underneath the fuel, which it helps to atomize by forming bubbles. The fuel enters through the brake jet *b*, Fig. 14, and is delivered through spray jet *dd*. The channel *a* leads to the starting jet. The conical surface *cc* forms a tight joint separating the jet mechanism as a whole from the contents of the float chamber. The latter, BB, Fig. 13, is pressed and very light and secured by a large nut *nn*. The float RR is of the annular type, which, however, makes it less accessible, so that it is not so easy to load it down when a heavy fuel is used. The ideal would therefore be a Pallas carbureter with a lateral float chamber on the plan shown in Fig. 15 and also with the method for float adjustment used in the Lyma carbureter.



Figs. 16, 17, 18—Means for adjusting float level

A lateral float can readily be adjusted to the specific gravity of the fuel by placing perforated disks or shims on it. With the Lyma carbureter this adjustment is accomplished as follows: Fig. 16 represents a float dipping into light fuel to the depth S, just clearing the bottom of the chamber. In Fig. 17 the float is in a heavier fluid and begins therefore to float at a smaller depth of immersion *s*. Both the light and the heavy fuel must reach the level of the dotted line, in the chamber and in the jet, for normal work. This can be effected by making the abutment *aa* adjustable. When the float spindle strikes against the abutment the feed valve *v* is closed in both cases and, if the abutment *aa* is placed higher for the heavier fluid, as indicated in the illustrations, the level in the jet can be the same as for the light fuel. The abutments can also be made adjustable by having the fulcrums *m* movable, and this is the expedient used in the Lyma carbureter, the mechanism being shown in Fig. 18. The fulcrums *nn* here correspond to *m* in Figs. 16 and 17, and the lowest points *aa* of the balls to *aa* in these diagrams. The fulcrums *nn* are secured in a red-brass casting *rr* which can be screwed up and down in the cover of the float chamber by means of the high-pitch thread *gg* and the crank *k*.

The crank can be turned 240 deg. and this allows for a change of specific gravity from .65 to .92. A dial on the cover gives the intermediate figures, so that it is easy to place the crank arm in the proper place for each fuel—for benzol at .88, for example, for alcohol at .82 and for ordinary gasoline at .72.

The Lyma can be counted among the brake jet carbureters, because the fuel feed at high motor speed is so much reduced by means of a throttle-jet that the air feed through the other intake is very much increased, on the plan shown in Figs. 19, 20, 21 and 22.

The fuel is not thrown out in a stream from a jet in this

(*Continued on page* 298)

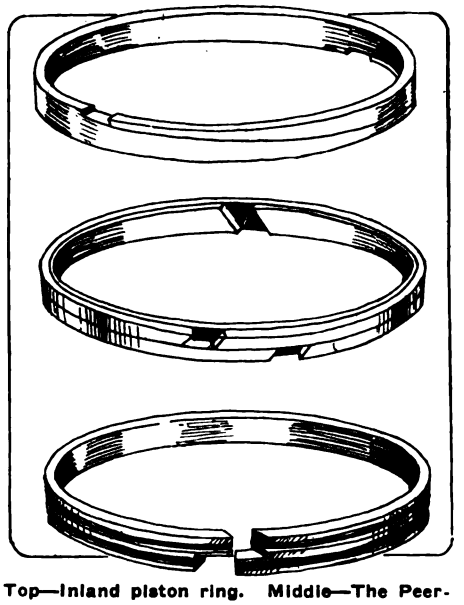
ACCESSORIES

Peerless Piston Rings

THERE are three sections in the Peerless piston ring, there being two outer rings, each half the width of the ring groove in the piston, and these are superimposed on a wide inside ring, the latter being as wide as both the outer rings together. All joints are broken while the proper spacing is maintained by means of small pins. The joints are simply diagonal cuts. Wherever there is a joint there is a seal formed by the solid metal of another ring, so that there is no passage left for gas or oil leakage. Peerless rings are all made eccentric. Stock sizes are from 2⅜ in. in diameter to 6 in. in diameter while the widths vary from 3/16 to ⅜. Prices: All sizes up to and including 3½ in., $1.75; up to and including 6-in. size, $2.—Peerless Piston Ring Co., Newark, N. J.



Top—Inland piston ring. Middle—The Peerless ring. Bottom—No-Leak-O ring

Inland Piston Ring

A novel design of piston ring has been brought out under the name Inland. It is a one-piece concentric type featured by the fact that the end joints of the ring are absolutely staggered and hence there is no possibility of aligning the joints and hence causing leakage.

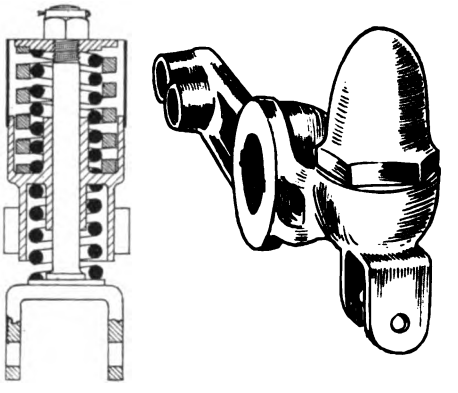
The ring is a concentric design and is cut on a spiral with the free end tapered thus, according to the makers, giving the advantages of the eccentric type. To get the advantages of concentric design the free ends are so supported, as shown in the accompanying illustration, that they give uniform thickness to the entire cross-section. A third advantage which is stated to correspond to that secured in more than one-piece ring, is given by the fact that the rings are slotted to less than one-third their width at opposite points on the circumference of the ring. The object of the construction is to give uniform pressure at all points on the cylinder walls with sufficient elasticity to render them harmless to the cylinder. The distortion of the rings is unlikely as heat-treatment is given before grinding. The price of the ring depends upon the size employed.—Inland Machine Works, St. Louis, Mo.

No-Leak-O Piston Rings

The No-Leak-O piston ring is distinguished by the use of a step-lap joint, a groove between the sliding face forming the step-lap joint on the side of the ring. It is this latter groove which makes this ring different from others on the market which employ the step-lap joint. The joint gives a tight seal at the ends of the ring while the oil fills the groove which forms a seal around the ring giving a tight fit and preventing the escape of gas. At the same time the oil lubricates and forms a packing or seal against the oil being drawn or forced up into the firing chamber.

The grooves control the oil. The cylinder walls are constantly lubricated by the oil from the grooves and the grooves take up fresh oil as fast as the supply is depleted by lubrication. This oil seal is said by the manufacturers to greatly reduce the quantity which works its way up into the combustion chamber.

The rings are made in one piece from seasoned stock and are stated to be resilient and not to clog or lose their efficiency. The price varies, of course, with the size employed.—Automobile Accessories Co., Baltimore, Md.



Left—O.M.C. light car type shock absorber. Right—Hup absorber for model 32 Hupmobiles

Hup Shock Absorber

Shock absorbers for model 32 Hupmobiles use a helical spring for absorption of shocks, the spring being contained in a bracket, as illustrated herewith. Adjustment may be made by removing the cap inclosing the spring and turning a hexagonal nut on the spring bolt. Price is $10 per pair.—Miller & McLean, New York City.

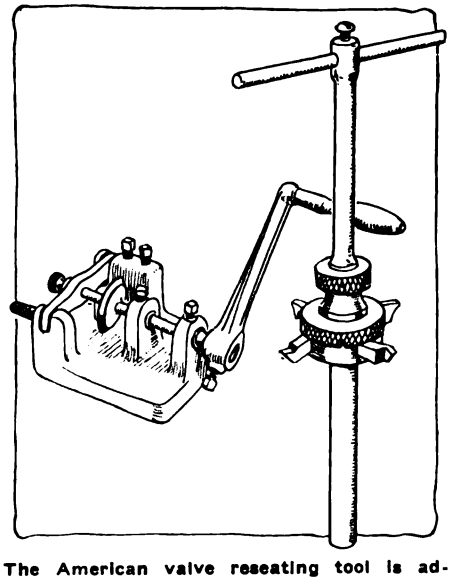
O. M. C. Shock Absorbers

O. M. C. shock absorbers are made in two distinct types, one for heavy and the other for light cars. Though differing considerably in constructional details, they are alike in one respect: they are designed to check excessive spring movement both up and down—in other words, they are double acting.

The heavy car type is made with two cylinders. The plunger rod carries at its lower end a piston which works in a liquid. A valve in the piston opens only when the piston rises; when the piston descends the only passage for the liquid —oil—is through a few small holes. The upward movement of the piston is resisted by a coiled spring.

When the leaf spring of the car is compressed the coiled spring is brought into play; when the rebound occurs the hydraulic brake acts, easing and checking the up-throw. Thus the piston rises without hydraulic resistance, but is checked by the oil on its descent.

The light car type employs springs only and the cylinders are single—that is, there is one cylinder for each car spring. The cylinder is divided into two compartments, as the accompanying illustration shows. In the upper one is the main spring, which is double, the outer and heavier spring, of square section steel, being reinforced by the inner and lighter spring, of round steel. The lower compartment contains a single spring of round section. The cylinder slides on the central rod, the upward



The American valve reseating tool is adjustable to any valve

movement being checked by the two upper springs and the downward movement by the lower single spring. Prices are: Heavy car type, for cars of 1500 to 2000 lb., $35 per pair; to 2600 lb., $35; to 3300 lb., $40; to 3900 lb., $40; to 4500 lb., $45; over 4500 lb., $45.

Light car type, for Fords, $8 per pair; $15 for four.—A. J. Picard & Co., New York City.

American Valve Reseaters

American valve reseating tools can be adjusted to suit the valves of practically any car. The valve facer consists of a cast iron base with bearings for a short shaft mounted directly in line with a bushing for the valve stem, and a holder at one side for the cutting tool. The valve is placed with its stem in the bushing and the shaft turned by means of a crank, driving the valve through a connection provided for the purpose. By adjusting the cutters to the proper distance from the center valves of any size can be faced. Six bushings of different sizes are furnished.

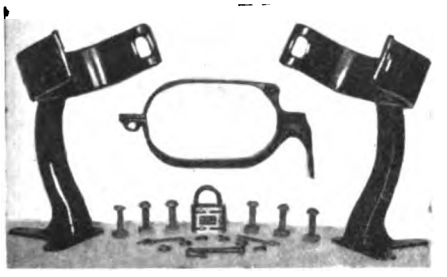
The seating tool consists of a head carrying four cutters, a stem entering the valve stem guide, and an upward extension with a T-handle for turning the tool. On the cutter head are two large knurled nuts; turning one loosens the adjustment and turning the other sets the cutters to any size within the range of the tool. When set, turning back the lock nut holds the adjustment. Two sizes are made, one seating valves up to 1¾ in. and the other from that up to 3 in. Price, either size reseater, $6; facing tool, $6; seater and facing tool together, $10.—American Valve Tool Co., Stamford, Conn.

Sly Overland Tire Lock

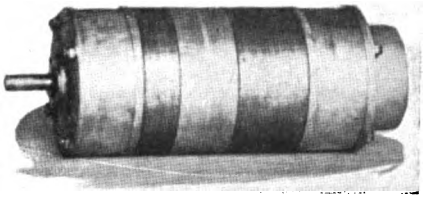
A tire lock designed especially for Overland cars is manufactured to take the place of the upper strap which holds the tires. To attach the lock two cap screws which hold the bracket for the top strap are removed with a socket wrench and the lock put in its place, using the same bolts. When the tire is in place the bolts cannot be removed. The locks are made in two types, single and double. Price, single, $1.50; double, $1.75.—W. W. Sly Mfg. Co., Cleveland, Ohio. Distributed by New Era Spring and Specialty Co., Detroit, Mich.

Apco Ford Tire Holder

A tire holder designed to carry the extra demountable rim or spare wheel on Ford cars is announced by the Auto Parts Co. It resembles in construction the side tire holders which have been brought out for Fords by the same concern and includes an automatic locking clasp which permits of easy and rapid removal or replacement of a spare. The new design is for attachment to the running board and the clasp is provided



Apco tire holder for Fords with fittings



Rae motor-generator for Ford cars

with an easily operated lock. The makers claim that a spare can be removed or replaced in 5 sec. The retaining screws are not accessible when the clasp is closed so that it is impossible for thieves to readily remove the holders. Finished in black enamel the new holder sells for $2.—Auto Parts Co., Providence, R. I.

Autoprotector

The Autoprotectors are instruments to be mounted on the front axle of a car or truck and connected with the throttle, the air supply or the ignition system in such a way that if the car is driven too rapidly over rough roads or under other conditions that subject it to severe shocks, the car will be slowed down or even temporarily stopped. The device is adjustable as to the severity of the conditions under which it will commence to act and can be sealed.

Inclosed in the casing is a weight which is held in normal position by a spring, but which is displaced by sudden shocks and is prevented from returning immediately to its normal position by a dashpot, the piston rod and piston being attached to the bottom of the weight. The weight is connected to the Bowden wire which acts on the throttle, air supply or ignition. A succession of shocks will tend to keep the weight out of its normal position and the speed of the motor will be affected in proportion to the amount of displacement of the weight. A counter attached to the device shows the number of abnormally severe shocks experienced, and this acts as an additional check on the driver. The device commences operating as soon as the first shock is transmitted to it. Price, with counter, $25; without counter, $18.—Autoprotector Co., Dorchester, Mass.

Rae Ford Electric System

The Rae is a small, simple motor-generator for starting and lighting Ford cars. It is used in connection with a 12-volt battery and operates at one and a quarter times crankshaft speed when running as a generator, while as a starter it is claimed to turn over the motor at 400 r.p.m. The starter action is actuated by pressure on a button, the connection being electrical. The Rae unit, which is shown in the accompanying illustration, is furnished with the necessary wiring, cutout, etc., and is installed so that the drive is directly from the crankshaft by silent chain. It is mounted on a saddle secured by three cylinder-head bolts and is supported by a bracket attached to the motor base.—Morgan Electric Co., Detroit, Mich.

Rels Brazing Metal

This product is a metal for brazing or soldering aluminum; the metal is too hard for use with a soldering iron, so a gasoline torch or its equivalent must be used. The surfaces to be united are heated to bring all oil to the surface and are thoroughly cleaned, scraped bright and the abutting edges chamfered, much as in ordinary brazing. The surfaces are tinned with the metal, no additional flux being required, and are united by running in more metal to fill up the V formed by the chamfers. The metal sells for 50 cents per bar.—Rels Mfg. Co., Brooklyn, N. Y.

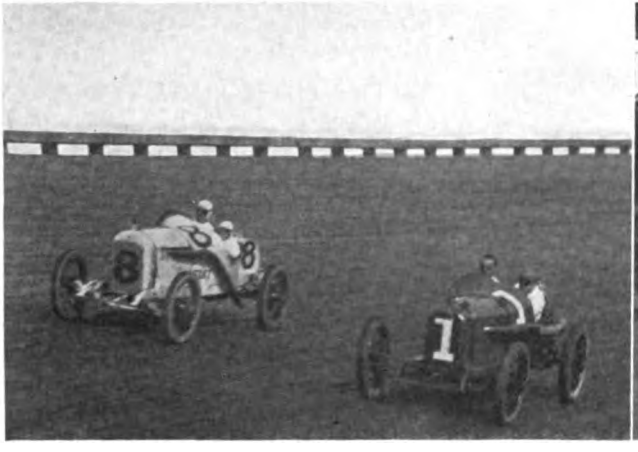
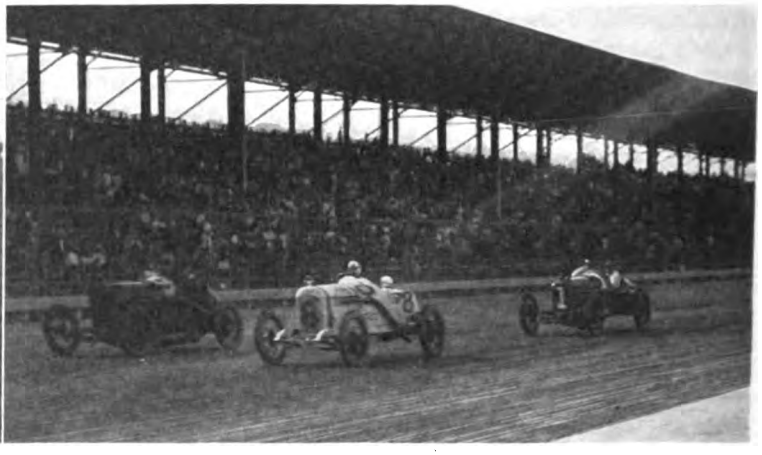
Resta Wins Century at 101.86 M.P.H.

Battles with Stutz for Leadership Until Tires Turn Scales —Burman is Third





Left—Cooper passing Resta on a turn and taking the lead only to lose it on the straightaway. These two ran wheel to wheel for 80 miles, averaging 104 m.p.h. Right—Passing the grandstand—left to right—Burman (9), Cooper (8) and Resta (1). Burman drives 104 m.p.h. and passes Cooper running second to Resta on the 28th mile.

CHICAGO, ILL., Aug. 7—The distinction of winning the first automobile race in America at a speed of over 100 m.p.h. was carried off by Dario Resta at the 2-mile board speedway here to-day by winning the 100-mile challenge race at a pace of 101.86 m.p.h. and defeating his three rivals Cooper in a Stutz, Burman in another Peugeot and Oldfield in a Delage. Resta put his Peugeot over the 100 miles in 58 min. 54.2 sec., finishing 52 sec. ahead of Cooper who was the only real rival he had. Burman was nearly 3 min. behind, having had two stops for tire troubles as compared with one stop each by Resta and Cooper; and Barney Oldfield, whose new Delage with four carbureters was not well tuned up, stopped at the end of 96 miles, having been lapped several times by the other drivers. Cooper's average was 100.58 and Burman's 97.78 m.p.h.

Fully 20,000 spectators sprinkled through the huge grandstand, in the bleachers, on the back stretch, and from the parking spaces in the infield, watched the 100-mile challenge duel, the first of the kind ever held on a speedway in this country. The weather was perfect and the track in condition. The four cars were sent away at a flying start, Oldfield having drawn the pole position acting as pacemaker. Resta was second from the pole. Cooper third and Burman on the outside.

From start to finish the race was Resta's. His Peugeot was seen to have the necessary speed, although from the start Cooper disputed the laps with him. Burman had apparently a lot of speed, but when he began to show it he ran into tire troubles and fell behind leaving Resta and Cooper to dispute the lead. Both Resta and Cooper made one tire change each. Resta changed a right rear at 74 miles and momentarily Cooper shot his Stutz into the lead, the crowd cheering to the echo as the Stutz entry was the real hero of the day with the grandstand and bleachers. Resta made the change in 35 sec. but was nearly 56 sec. behind Cooper when he got going again. This put him nearly three-quarters of a lap behind. He started, setting a faster pace to overtake the Stutz, but at 80 miles Cooper was seen to slow up on the back stretch; a right rear had given way and he had to travel at reduced speed for a mile to the grandstand pits. In the meantime Resta had seized the moment and was back in the lead.

Before Cooper could make the change and get out Resta had a lead of 51 sec. on him, or nearly three-quarters of a lap. With only 20 miles to go Resta at once slowed down from a momentary pace of nearly 110 m.p.h. to 102 and held it until the finish. In the meantime Cooper was pushing his Stutz, gaining each lap, but there was not enough time remaining to overcome Resta's lead, and he finished 52 sec. behind.

The average speed of 101.86 m.p.h. for the century does not represent the real speed of the race, the stops made by Resta and Cooper cutting the speed from 104.35 m.p.h. which the leaders had maintained from the start up to over the 75th mile when tire troubles began. Many expected that the pace would be much faster at the start as it had been in the opening 500-mile race in June, but the drivers apparently profited by the experience and decided to hold a rather conservative pace at which the tire troubles would be a minimum. Last June the pace set at the start was 108 m.p.h. and tire troubles started at 17 miles and before 25 miles were covered there were many tire changes. To-day the pace for the first 10 miles was 104 m.p.h. and practically this pace was maintained until the finish. The first five laps are a fair criterion of the speed as follows: Lap one, 101.41; lap two, 104.35; lap three, 105; lap four, 104.65 and lap five, 104.65 m.p.h. From the 10-mile mark the pace was a steady one up to time of the tire troubles. All three cars, Peugeot, Stutz and Peugeot had higher speed possibilities which were apparently held in reserve.

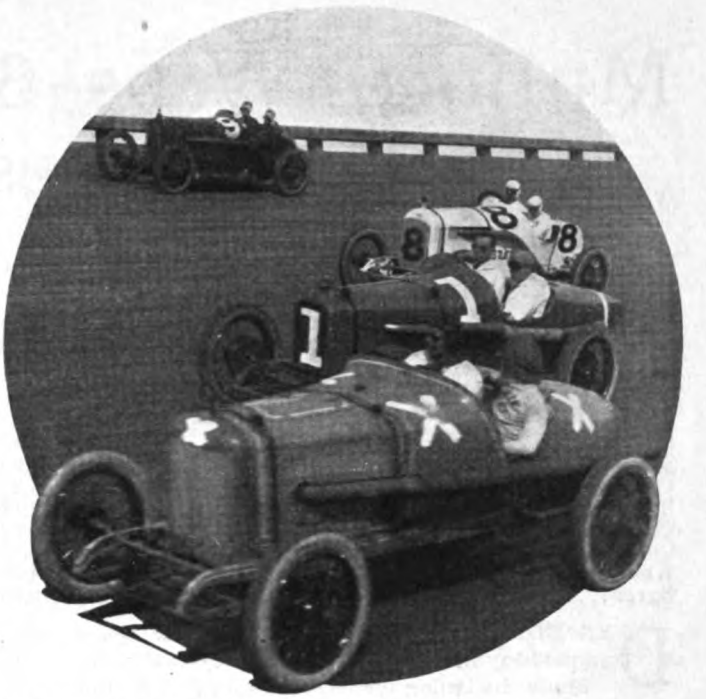
A Perfect Start

From the spectacular viewpoint there were some tense moments in the 58 min. of racing, but the grandstand did not have all the chances to applaud that it wanted. The start was perfect, all four cars were sent on a pace lap with Oldfield at the pole setting the pace. As the tape was approached the pace was easily 90 m.p.h. and all four crossed in a row, the red flag fluttered and they were off.

Lap two brought the first sensation, Cooper putting the Stutz into the lead at three-quarters and leading the Peugeot over the tape by three lengths. It was what the crowd wanted and it cheered. Burman was now 100 yards back, a position he held for nearly 20 miles. Lap three saw another change, Resta passing Cooper on the backstretch and leading over the tape by three lengths. The pace was 105 m.p.h. Lap four brought a thrill when Cooper and Resta were practically side by side, Resta leading by 2 feet. The next lap was Resta's by a length, so were the next three, but lap nine brought Cooper into the lead with a margin of two lengths. So the see-sawing continued. Resta led for three more laps, then Cooper took three in a row; Resta then took three more, Cooper sandwiched in one, then they alternated for three or four more laps, scarcely a length separating them. Resta would pull away on the straights and Cooper would ride fast on the bank and overhaul the Peugeot. This continued until the tire episodes at 74 miles, when the grandstand had its turns in cheering for respective favorites.

Burman's Tire Luck

Burman furnished his sensational burst of speed at the 25-mile point. Up to this time he had been trailing nearly 100 yards behind Resta and Cooper. Suddenly he started picking up a few yards on each lap, almost imperceptibly, when suddenly at the twenty-sixth mile he was on the heels of the leaders and crossed the tape actually a few inches ahead of Resta but a few inches behind Cooper who was leading. It was one of the spectacular parts of the race. The cars could not have been closer together and traveling at over 105 miles per hour. It was the moment the crowd had waited for, they were all on their feet, the air was filled with cheering. But this three-cornered duel, while not so spectacular, continued for the next twenty miles, Burman being mixed in the group at the end of each lap. The pace proved too much for his tires and at 42 miles he dropped back and had to change a right front, leaving Cooper and Resta to battle for the honors. From this time Burman was not up in front or near it again. He ran 20 seconds back, some laps gaining a few seconds only to drop them in others. At 72 miles he stopped again to change a right rear, and any driver who has to make two tire stops in a 100 mile race has little chance of winning.



The first lap on the curve—Burman (9), Cooper (8), Resta (1), Oldfield (X), approaching the starting line at 90 m.p.h.

Oldfield's tire troubles started earlier than might be expected for the pace he was setting. It was in the fifty-second mile when coming down the homestretch ahead of Resta and Cooper who were about to lap him the second time, that a right front tire blew, but his car never wavered. He stopped on the next lap and made a rapid change. He made two other stops.

Resta's Peugeot was lubricated by Oilzum. The times of the four drivers at every 10 miles of the race are given in the following tabulation:

Times in Chicago Challenge race at every 10 miles

Driver	10	20	30	40	50	60	70	80	90	100 miles

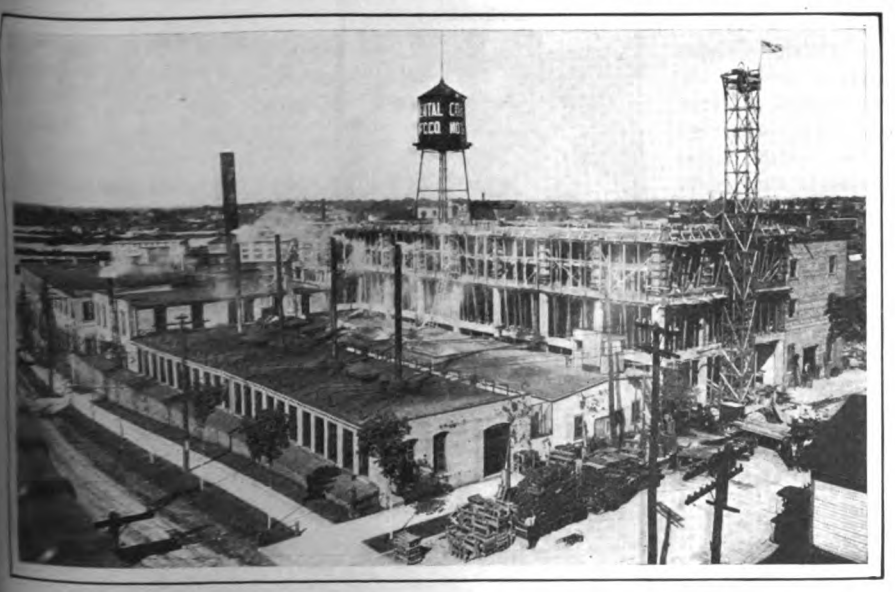
Continental Motor Adds to Muskegon Plant



MUSKEGON, MICH., Aug. 7—Two additions are being made to the already large Muskegon plant of the Continental Motor Mfg. Co., which is practically entirely devoted to the manufacture of four-cylinder motors. Also the main building, shown in the foreground, will soon need to be reconstructed to give more floor space. One of the new buildings illustrated as under construction is 54 by 150 ft., and the other is 70 by 330, the latter being V-shaped. Both buildings are four stories in height and together they will increase the floor space over 125,000 sq. ft. and will permit the doubling of the present working force of nearly 2000. The added facilities will raise the production of four-cylinder motors from 4000 to 6000 per month, and the cost will be from $300,000 to $400,000.

Mulford Wins 300-Mile Race on Des Moines Speedway

Finishes in Duesenberg 1 Min., 7 Sec. Ahead of De Palma's Stutz—Race Was Duel Between These Two and O'Donnell's Duesenberg—Two Serious Accidents Mar Contest

Order of Finish Des Moines 300-Mile Race

Duesenberg	Mulford	3:27:05.33
Stutz	De Palma	3:28:12.02
Duesenberg	O'Donnell	3:31:45.51
Du Chesneau	Brown	4:26:22.18
Clergy	Barndollar	4:40:35.02
Cooling	Henderson	5:01:43.25
White	Shrunk	5:09:54.13
Ogren	Alley	5:10:13.08

DES MOINES, IOWA, Aug. 8—The new 1-mile board speedway was opened in this city to-day by Ralph Mulford winning the 300-mile race in a field of eleven starters at an average speed of 87 m.p.h. and defeating by 1 min. and 7 sec. Ralph De Palma, who drove a Stutz and who was announced a winner after the race. Owing to the speed, the 1-mile track, and inadequate timing arrangements an error was made in the announcement and after hours of checking the lap records, Mulford was declared the winner and entitled to the $5,000 for first place, De Palma receiving $2,000 for second position.

The opening of this new speedway was unfortunately marred by two accidents, each of which resulted fatally. Joe Cooper, Sebring, Ohio, driving a Sebring, blew a tire in the thirty-ninth mile when running in second place, and close to De Palma's Stutz. The accident happened when traveling at 90 m.p.h. at the end of the turn into the home stretch. Cooper's left rear tire blew, swerving the rear end of the machine toward the inside of the track and putting the car at right angles on the track. Cooper fought to hold it on the track and succeeded in keeping it from running off the inside only to have it skid a distance of 30 feet into the railing at the top. This railing crumbled like tissue paper, and the car with the driver and mechanician fell over sideways to the ground below. Cooper was caught beneath the edge of the machine and died immediately. His mechanician, Peio, was thrown clear out of the car. The accident happened directly opposite the grandstand.

The other accident occurred in the 240th mile when William Chandler, traveling in fourth place, went off the track at the inside, due to the breaking of the left rear wheel. Before going off the track the car skidded half way up the board surface on the back turn, then turned over, and landed through the guard fence 40 ft. from the inside of the track. Chandler and his mechanician Keller were thrown clear, but Keller died a few hours later due to a combination of injuries, and Chandler is now out of danger.

Trio Fight Duel

The race from start to finish was a masterly fought duel among Mulford in a Duesenberg, De Palma in a Stutz, and O'Donnell in another Duesenberg. It was either Mulford or De Palma's race until 297 miles had been covered when the two were running wheel to wheel, and had been for 20 miles, when De Palma blew a tire, and although he made a speedy change it was impossible to catch Mulford. De Palma had tire difficulties all the way through the race, which kept him back at crucial points when he had practically control of leadership.

From the start, which was a flying one, after the co testants making a circuit of the track, De Palma took the le until the thirty-ninth mile, when he stopped for tires, a O'Donnell in his Duesenberg, who was trailing him clo pushed to the front. O'Donnell gradually increased his le and at 60 miles was a lap ahead and at 80 miles was a ahead of Mulford and three laps ahead of De Palma, who h again stopped for tires. O'Donnell's lead came to a sud end at 90 miles, when tire troubles stopped him and p mitted Mulford to take the lead with De Palma only a behind him. At 100 miles Mulford had held the lead carried off the $100 prize for leading at this mark, his ti being 1:07:06, a speed of 88.6 m.p.h. At this point O'Don was two miles back and De Palma four. At 98 miles Palma stopped for his fourth tire change.

Mulford's Tire Luck

Mulford made his first stop at 105 miles for tires, but to his lead and making a quick change he was able to ma tain leadership. He succeeded in holding it until near 200th mile, when O'Donnell took the lead due to tire trou by Mulford. O'Donnell carried off the $100 for leading the second century, the average being 86 m.p.h. At this p De Palma was a lap back and Mulford running in third sition was four laps back. From this point De Palma gra ally forged ahead, followed by Mulford. At 213 miles he only half a lap behind O'Donnell, who was leading.

The Race Crisis

At 320 miles the crucial event happened, O'Donnell and Palma both going to the pits together. This permitted M ford to gain his lost laps so that when the two got back the track, Mulford was on a par with them. From this p

Left—Joe Cooper, w Sebring car went over edge of the Des M speedway

Below—Where the car through the railing

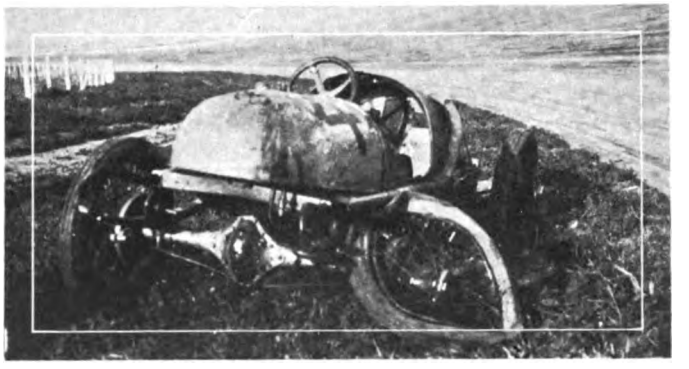
until the finish of the race there was one of the grandest struggles seen in speedway racing. For the next 50 miles O'Donnell, De Palma, and Mulford were all bunched.

Mulford Kept Out of Pits

De Palma was leading when O'Donnell's chances vanished due to his going to the pits for tires at 270 miles. This left Mulford and De Palma masters of track and road driving, to fight to the bitter end, and it was a great race between the two. De Palma held a slight lead until 289 miles, when Mulford lead him by a wheelbase. The two fought mile after mile on even terms until 294 miles, when De Palma took the lead and seemed a certain winner, barring tire troubles. Mulford was close behind and when De Palma's bad luck arrived at 297 miles, and the tire blew, it was Mulford's race.

Keeping out of the pits was what won for Mulford and going into them too often beat De Palma. Mulford made the last 100 miles without a single stop, and went to the pits only three times during the entire race. De Palma's last tire change when only 2 miles from the finish was made at lightning pace, but master effort was useless.

The other starters in the contest were not factors with the exception of Cooper, whose elimination came early. Chandler, who had fought up to fourth place with his Duesenberg at 225 miles, gave promise of being a factor at the finish, but was flagged out by fate at 239 miles. Tom Alley in the Ogren was running fifth but experienced motor difficulties. The O'Connell entry was out at the end of the eighth lap with engine trouble, and the White six entered by Shrunk went first to the pits at the thirty-second mile. Scott withdrew his



Chandler's car, which went off the track in the 240th mile at the Des Moines race

Anderson near the finish because of motor trouble. Brown took fourth place with his Duchesneau, and Barndollar was fifth in the Clergy. Henderson in the Cooling was sixth, Shrunk in the White seventh, and Alley in the Ogren eighth and last.

It was expected that trouble might arise because of the failure to properly check the scoring, but De Palma said he would not protest, although several technicalities could be raised as a basis for protest. He claims that he averaged 33 sec. for his seven tire changes at the pits and his longest stop was for gasoline and tire changes, which was 79 seconds. He says the track is all right and one of the best he had raced upon. His car was lubricated with Oilzum.

Official Time at Various Points in the 300-Mile Race on the Des Moines Speedway Aug. 7

Car	Driver	20 Miles	100 Miles	160 Miles	200 Miles	260 Miles	300 Miles

Iowa College Automobile Course at Fair

DES MOINES, IOWA, Aug. 7—The department of engineering extension of the Iowa State College at Ames, having conducted forty successful automobile institutes in cities and towns of Iowa, has arranged to offer a course of free lectures instructing the motorist concerning the proper care and operation of his car at the State fair, to be held here the week of Aug. 27.

Mr. Leavell, the lecturer, has had several years' experience in second-hand car, garage, and service station work, and has also been connected with the engineering departments of several prominent firms engaged in the manufacture of cars and accessories.

Much of the exhibit material which has been used in demonstrations throughout the State will be displayed. There will be a number of carbureters of the best known makes and models cut open to show the inside mechanism. Sections cut from damaged casings will be used to illustrate the common forms of tire abuse. There will be battery plates, pieces cut out of different types of radiators, spark plugs, and much other material of interest.

After 9 each morning Mr. Leavell will be in the automobile institute lecture room under the west end of the grandstand to answer questions relative to motor car troubles. The regular lecture will begin at 10. At the close of the lectures there will be opportunity for any one in the audience to ask questions for general discussion. During the afternoon Mr. Leavell will be available by appointment to discuss or explain individual trouble cases, and as far as possible to inspect and give advice concerning cars which are brought to within a reasonable distance of the lecture room. He will offer suggestions and advice concerning such work as the motorist should be able to perform for himself, and will point out what mechanical attention the car needs. He will not do any repair work himself. This will have to be done by those regularly engaged in such work. All of Mr. Leavell's advice and suggestions are given free.

Among the subjects which will be taken up in the lectures or will be touched upon in the general discussions at the close of the lectures are the following:

Care of Running Gear. Causes and Prevention of Spring Breakage. Spring Lubrication. Steering Gears. Alignment of Wheels. Care and Adjustment of Brakes. Types of Rear Axles. Types of Ball and Roller Bearings Used in Different Parts of the Car. Proper Lubrication and the Selection of Proper Lubricants for Different Parts of the Car, as The Engine, The Transmission, The Differential, The Wheels, The Clutch, etc. Methods of Manufacture of Oils and Greases. Radiators, Causes of Boiling, Effects of Impure Water, Anti-freeze Mixtures. Care and Attention of Electrical Starting Systems. Location of Troubles with Magneto and Battery Ignition Systems. Adjustments. Carbureters, Principle of Operation, Construction, Location and Remedy of Trouble. Fuels for Motors. Manufacture of Gasoline. Relative Merits of High and of Low Test Gasoline.

Six S. A. E. Men for Navy Committee

Howard E. Coffin, Hudson Motor Car Co. | William G. Wall, Nat. Motor Vehicle Co. | John G. Perrin, Continental Motor | A. L. Riker, Locomobile Co. of Amer.

NEW YORK CITY, Aug. 10—Of the nine members of the S. A. E. asked to accept nomination for positions on the Navy Department Advisory Committee, six have accepted and voting is now in progress for the final selection of the two representatives. The six members who have accepted nomination and whose names are now before the Society as a whole for selection are Louis S. Clarke, vice-president and consulting engineer, the Autocar Co.; Howard E. Coffin, vice-president, Hudson Motor Car Co.; A. L. Riker, vice-president and chief engineer, Locomobile Co. of America; John G. Perrin, consulting engineer, Continental Motor Mfg. Co.; William G. Wall, vice-president and chief engineer, National Motor Vehicle Co., and Rollin H. White, first vice-president of the White Co.

Car and Carbureter Design for Driving with Any Fuel

(*Continued from page* 291)

device, and it can be classified as a surface carbureter with a throttle-jet. A portion of the air supply passes, as indicated by the arrow in Fig. 19, over the fuel level in the tube *R* which connects with the float chamber. The amount of fuel entering this tube is regulated by an easily adjustable throttle valve, and the level in *R* therefore becomes high when the motor is resting, making starting easy, while the level drops when the speed is increased, so that then more air is drawn in. As said, it is only a portion of the air which passes over *R*, the main intake being at *H*. The charged air strikes the large metal cone *M* which is the organ for closing and regulation of the carbureter. When the motor is shut down this cone comes to rest against a large metallic surface and is thereby kept warm, so as to assist in starting after any brief rest period.

The air channel *G* does not lead to the atmosphere, as Fig. 19 would suggest, but branches into two pipes, 1 and 2 in Fig. 20, the first one leading to the lower portion of the carbureter and the second through the top of the float chamber. The channel *G* also has a fresh air inlet at *l*, though only in the vertical model, the Lyma being manufactured in both vertical and horizontal models, like the Zenith.

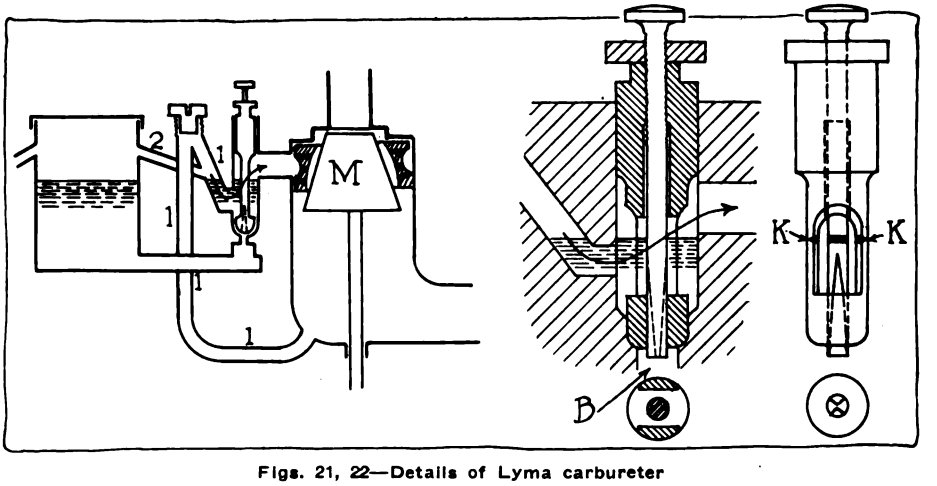
In reality the pipes have not as simple a course as shown in Fig. 20. Channel 1 does not dip downward at once but is first sent upward as in Fig. 21, with the object of forcing the air to bubble through the fuel so long as this stands high—for starting and at low speeds.

In the horizontal Lyma there is an additional organ, consisting in a ring-shaped body (shown hatched in Fig. 21) with a number of narrow passages through which the gas mixture must flow before it strikes the cone *M*.

The organ for throttling the fuel, which is sketched into Fig. 21 and shown in detail in Fig. 22, is easily removable, being held in position only by a spring in the same manner as the float chamber cover is now in many carbureters held down only by a spring and a catch. The double-hatched part is held down by such a spring, so as to make its lower spherical surface form a tight joint against the fuel entering at *B*, Fig. 22. The fuel rises, however, through tapered slits in the spindle of the organ, and if this spindle is raised or lowered—by thread and locknut—the slits give a larger or a more restricted channel for the admission of the fuel. When the adjustment has been found at which the motor works best, a slight notch is filed at one point—such as *KK* in Fig. 22—so as to make it easy to find this most favorable position again after the spindle has been removed for cleaning of a possibly clogged slit.

The Lyma carbureter has also an arrangement for introducing fresh air in the cylinders during coasting, but the channel provided is much too narrow. Another device for automatic adjustment of a slide to proportion heated and cold air is probably also of small value, as it is not found in the horizontal model. The greatest merit in Lyma design is the provision for adjusting the float to the fuel gravity.

[Von Löw concludes with the statement that he will not return to gasoline after the war and the prediction that others who do so, rather than arranging to use all fuels, will be disappointed].



Figs. 21, 22—Details of Lyma carbureter

Cantilevers Come Slowly

NOW that so many new models are announced it is obvious that European history will repeat itself in America with respect to cantilever springs. In both hemispheres the cantilever spring is an old idea and it has been used for many years. But for no very apparent cause a sudden wave of enthusiasm for it appeared in Europe between two and three years ago and this has been followed by a similar wave in America. At the S. A. E. meeting in New York last January, everyone was talking cantilever springs, and the wildest sorts of claims for them were to be heard, yet we now see that only quite a few of the new cars are being fitted with anything novel in the way of suspension.

Presumably the truth is that the cantilever spring has been tried out extensively and has shown peculiar adaptability to certain chassis while proving a difficult problem on others. As a spring it may be good or bad just as any other sort of spring can be, but there is now a fairly prevalent idea that a good cantilever spring layout is decidedly more costly than a semi-elliptic or three-quarter design.

It is highly satisfactory that there has been no rush to use the type until its good and bad points were discovered, and the present situation suggests that its popularity will now increase in proper proportion to its merits without any spurious advantages being claimed for it.

Industrial News Service

IT is a matter of regret that an ancient and honorable contemporary, in the curtailment of its activities, should belittle the sphere of usefulness of the entire industrial press, to bolster its change of policy. It openly directs the automobile industry to the daily press for the news of the industry. In so doing it ignores the foundation principle of industrial journalism. We appreciate the usefulness of the daily press on general topics, but in an age of specialists no individual or organization can specialize on everything. The business man, therefore, depends on the daily press for the great sensational events of the day, and on the industrial press for an accurate record of the developments of the industry with which he is associated. Whether these facts are needed daily, weekly, monthly or yearly depends on the reader's activity, but in the automobile field we have no confidence in a constituency satisfied with a mortuary news service when every opportunity exists for authentic weekly information.

The automobile industry in exceeding its most sanguine expectations has established new records for industrial development; each week is punctuated with some salient event, and the automobile press owes it to the industry to accurately record such, not in a cursory manner, but with authentic details. The daily press, aware of these facilities, looks to the business press for authentic records of development, knowing as it does its impressions are furnished by those not familiar with the warp and woof of the industry.

We are, however, pleased to see our contemporary waking up to the facts of specialized journalism, and devoting one issue to the engineer and the other to the dealer. This will probably result in two separate and distinct monthly issues, which follows our conception of separate publications for consumer, dealer and manufacturer, instead of the blanket sheet idea.

Just how much will be lacking in this elimination of industrial news service and what influence this will have on the character of the circulation satisfied with this deficiency will be of special interest.

The Return of the Worm

NOT so long ago these was vivid interest in American automobile engineering circles regarding the use of worm drive for pleasure cars, and there were many who thought the worm would come. Then the spiral-type bevel made its appearance and the wave of interest largely died. What, however, it is now being asked, is the probable effect of the low gear ratios now so usual, and there are many who are again looking to the possible coming of the worm.

One of the disadvantages of the worm-driven axle is the fact that it must have a rather large center case and so give clearance trouble either beneath the axle or above, according to whether the under or over position is chosen. But with bevel ratio of 5 to 1, the clearance difficulty is coming up again and the worm is little, if any, worse for the same reduction.

Earl Overland Vice-President

Leaves Hendee Mfg. Co.—To Assume Duties Oct. 1—Is a Director

TOLEDO, OHIO, Aug 9—C. A. Earl, vice-president and general manager of the Hendee Mfg. Co., Springfield, Mass., has resigned to become vice-president and director of the Willys-Overland Co., this city. He will assume his duties Oct. 1. For over twenty years Mr. Earl was with the Corbin Screw Corp., New Britain, Conn., and after it became a unit in the American Hardware Corp. he became first vice-president of the latter. He resigned this position and that of general manager of the Corbin business last year to become vice-president and assistant general manager of the Hendee company.

His experience has been such that he is not only a manufacturing executive, capable of organizing and directing a factory on lines of maximum efficiency, but he is an experienced director of sales policies and organizations, and at the same time enjoys a high place in the esteem of Boston and New York banking houses, who have reason to know his capacity in large financial matters.

—

Overland Declares a 48-Hour Week

TOLEDO, OHIO, Aug. 6—Forty-eight hours will constitute a week's work for the 20,050 Willys-Overland factory employees after Nov. 1.

Though the regular working hours of all employees will be reduced from fifty to forty-eight hours a week, no reductions in daily or weekly pay are to be made. The reduction of working hours without corresponding decrease in pay is equivalent to a raise in pay proportionate with the reduction of hours of labor for all employees.

Under the new time and rate schedules time and one-half will be paid for all overtime and double time will be paid for services on Sundays and holidays.

The move follows an increase of 5 per cent in wages granted about six weeks ago.

It is announced that night and overtime forces will not be reduced so long as the demand for Overland cars keeps so far ahead of the factory's production.

—

Locomobile Adopts 8-Hour Day

BRIDGEPORT, CONN., Aug. 9—Acceding to the demand of the machinists working for the Locomobile Co. of America here, president S. T. Davis today conferred with a delegation of employees and conceded an 8 hr. day, thus avoiding what might have been a serious tie-up of the plant which is now being rushed to capacity on large orders for motor trucks from abroad. The question of wages for this working schedule will be taken up at a board of directors meeting to-morrow. Mr. Davis will report to the committee next Thursday. The men demand the same rates for an 8 hr. day as formerly received for a 10 hr. day. Previously they had rejected a bonus proposition made to them by the Locomobile officials.

—

Lyons Atlas Discontinues Cars

NEW YORK CITY, Aug. 11—The Lyons Atlas Co., Indianapolis, Ind., manufacturer of the Lyons-Knight motor car, it is believed will temporarily discontinue the manufacture of automobiles, and confine its activities to the manufacture of engines and parts for the automobile industry. Some change in manufacturing policy of this nature has been trade rumor in the Hoosier capital for some time. The general impression is that while present plans are to cease manufacture for the time being, there is a possibility that the company may reconsider manufacturing at a later date. The company's new test cars are still undergoing road tests, but some of the automobile experts in connection with the factory have been released from their duties.

The Lyons Atlas Co. for years manufactured poppet valve types of motors for the trade, and over 3 years ago announced the manufacture of the Knight sleeve-valve motor for general use. Soon after this, the company decided to manufacture cars fitted with this motor, which policy has been continued up to the present.

—

Bosch Has 8-Hour Day

PLAINFIELD, N. J., Aug. 7—The Bosch Magneto Co., the largest of the nine Plainfield factories, in which the machinists have threatened to strike, announced to-day that it had granted the demand for an eight-hour day. This is acceptable to the men.

—

Vacuum Oil Raises Wages

BAYONNE, N. J., Aug. 7—Officials of the Vacuum Oil Co. have announced an increase of wages for the 800 employees to take effect at once. Those receiving less than $2.50 a day are to get an increase of 10 per cent and those receiving $2.50 or more are to be given 25 cents a day more.

—

Gasoline Advanced 1 Cent

OKLAHOMA CITY, OKLA., Aug. 10—The Pierce Oil Corp. advanced the price of gasoline 1 cent for its distributing stations throughout the State.

Sun Six Detai Announced

L-Head 3 by 5 Power Plan Touring Car and Roadste —Territory Assigned

BUFFALO, N. Y., Aug. 9—Specifica of the Sun light six which is now b manufactured in this city and three products of which will soon start transcontinental run have just been r public. The motor is an L-head 3 by 5, designed to develop 50 hp the block. It is a unit casting, inclu both intake and hot-air connections, ing a clean exterior. The reciproc parts have been lightened and the n is primarily a high-speed design. clutch is a three-plate dry disk mounted, with the gearset, in unit p plant form with the motor. Gas feed is by the Stewart vacuum syst

The three-speed gearset has its shaft mounted on annular bearings the countershaft on plain bearings. rear axle is three-quarter floating a carried on ball and roller bearings. housing is of pressed steel and c the 3¼ by 52-in. semi-elliptic rear s which is used in connection with H kiss type drive. The spring is des to be approximately flat under load frame is of channel section 4½ in and 42 in. wide in the rear taperi 28 in. in the front width. The whe is 116 in. and the tread 56 in., wi option of 60 in. if desired.

The body designs are two in n a five-passenger streamline type or passenger roadster. The equipme cludes Remy or Westinghouse st lighting and ignition, with single wired on a single system. The c Brewster green, and although th is not yet announced, it is given o it would be less than $1,000.

Sales Managers Appointed

Territorial divisions have been and the sales managers and thei tories so far assigned are: C. H. for Ohio and Pennsylvania; G. A. for Michigan, Iowa and northern I J. E. Newell for Arkansas, Miss Louisiana, southern Illinois, easte souri and parts of Indiana, Kentu Tennessee; G. A. Jones for Kansa homa, Texas and western Misso L. Dixon for New York and V with the exception of New York C

The officers of the company Crawford, who was formerly sa advertising manager of the Hayn pany, is now vice-president of concern; R. C. Hoffman, who h wih Case, General Motors, Am Haynes, is engineer and pr manager.

Automobile Exports $68,107,818

Total for Fiscal Year Doubles 1914—June Increase Is Sixfold

1914 to June 30.		1915 to June 30.	
No.	Value	No.	Value
Cars ...28,506	$25,392,963	23,880	$21,113,953
Trucks . 784	1,181,611	13,996	39,140,682
Parts	6,624,232	....	7,853,183
	$33,198,806		$68,107,818

June, 1914.		June, 1915.	
No.	Value	No.	Value
Cars ... 1,982	$1,870,882	4,418	$4,785,998
Trucks . 90	120,257	2,990	8,578,802
Parts	473,968	....	1,139,182
	$2,465,107		$14,503,982

WASHINGTON, D. C., Aug. 11—Exports of automobiles and motor trucks have reached a total in the year ending June, 1915, far in excess of any previous 12 months. They totalled $60,254,635, made up of motor trucks to the value of $39,-046,892 and automobiles valued at $21,-113,953. This value represented 37,876 vehicles made up of 13,996 motor trucks and 23,880 passenger cars. To this can be added parts to the value of $7,853,183, giving a total of $68,107,818.

Trucks Gain Eighteenfold

When these figures covering the year are compared with the previous year, namely that ending June 30, 1914, the increase becomes apparent. During the year ending June 30, 1914, the total value of automobiles and trucks was $26,574,-574, showing that exports have more than doubled during the past year, the war conditions being entirely responsible for this. In the fiscal year ending June, 1914, only 784 motor trucks were exported as compared with 13,996 during the past year; in other words, the truck exports have increased eighteen fold during the year.

The war has not had such a favorable effect on the export of passenger cars, which has decreased during the past year from 28,506 to 23,880, a net decrease of 4,626 machines. This is explained by the fact that the demand for passenger vehicles during the early part of the war year was not great. The total value of the 784 trucks was $1,181,611; and the value of the 28,306 passenger cars $25,-392,963.

Sixfold Increase for June

The export figures for June, 1915, show 2990 motor trucks valued at $8,-578,802, and the export of passenger cars valued at $4,785,998. During June, 1915, the exports of automobile parts, not including engines and tires, amounted to $1,139,182.

Contrasting the business in June, 1915, with June, 1914, great export gains are registered all along. June, 1914, recorded 90 motor trucks exported at a value of $120,257, in other words the exportation of motor trucks was thirty-three times greater in June, 1915, than June a year ago.

In June, 1914, 1982 passenger automobiles were exported, valued at $1,870,-882; where as in June, 1915, there were 4418 automobiles exported, valued at $4,785,998.

Monitor Eight and Four at $1,075 and $795

COLUMBUS, OHIO, Aug 9—Two cars, an eight and a four, have been put out by the Cummins Auto Sales Co., under the names of the Monitor 8 and the Monitor 4-30. The eight is listed at $1,075 and the four-thirty at $795, both f.o.b. Columbus, Ohio.

The motor of the eight is a Golden, Belknap & Swartz unit with its cylinders cast in two blocks at 90 deg., and having 2¾ by ½ dimensions. The heads are removable from this motor, as is also the bottom of the crankcase. This motor has a single camshaft and is oiled by a combined pressure and splash system. The drive is through a multiple disk clutch to a three-speed selective gearset, then through a driveshaft fitted with two Spicer universal joints to a Timken rear axle. The wheels are artillery type, with 33 by 4 tires, and the springs three-quarter elliptic. The body is a five-passenger design equipped with a mohair top and jitney jiffy curtains. The equipment is complete, including Stewart speedometer, double ventilating windshield, a complete set of tools, robe and foot rails and tire carrier. Gasoline feed is by the Stewart vacuum system.

The Monitor 4-30 has its four-cylinder L-head 3¾ by 4¼ motor cast in a block. It has a unit power plant with three-point suspension, including a multiple-disk clutch, three-speed gearset and center control units. The drive is by shaft, the propulsion being taken through a torsion tube. The rear axle is floating and the wheels 32 by 3½. The gasoline tank is carried in the cowl and has a capacity of 10 gal. The wheelbase of this car is 108 in., being 4 in. shorter than the eight. Electric lighting and starting is included on both these cars.

Church Packard Assistant Chief Engineer

DETROIT, MICH., Aug. 6—H. D. Church has been appointed assistant chief engineer of the Packard Motor Car Co. Mr. Church joined that company six years ago and for the last five years has held the title of truck engineer. H. T. Woolson, who has been chief engineer of the Gas Engine & Power Co., Morris Heights, N. J., succeeds Mr. Church as truck engineer.

Budlong Resigns from Packard

Becomes Vice-President of Gaston, Williams & Wigmore

NEW YORK CITY, Aug. 11—Milton J. Budlong, president of the Packard Motor Car Co. of New York, Chicago and Philadelphia, has resigned to become vice-president of the importing and exporting firm of Gaston, Williams & Wigmore, Inc., of 140 Broadway, this city. He has been with the Packard company 7½ years.

He will be succeeded as president of the Packard Motor Car Co. of New York by E. B. Jackson, manager of the Philadelphia company, who will retain the general supervision of that organization. H. M. Allison, who for years has been manager of the Packard Motor Car Co. of Chicago, will follow Mr. Budlong as its president.

Mr. Budlong entered the automobile industry about 12 years ago, when he became secretary and treasurer of the Siemens & Halsky Electric Co. of Chicago, which was then controlled by the Electric Vehicle Co., Hartford, Conn. He later became president of the Hartford company, where he remained about 3½ years. During the Selden litigation, Mr. Budlong became general manager of the Association of Licensed Automobile Manufacturers, remaining in this capacity for about 8 months. In 1908 he joined the Packard company.

New Mack Models Coming

NEW YORK CITY, Aug. 10—The International Motor Co. is preparing a new line of heavy chain-driven Mack trucks which it is expected will not be ready before Jan. 1. These vehicles have been undergoing very thorough tests in actual service, one of them being in use at the National Guard maneuvers at Plattsburg, N. Y. at the present time.

The International Motor Co. is increasing its export trade through the efforts of its export department, located in a separate office in New York City in charge of W. T. Stevens, who is sending representatives into Africa, South America, India, China, Japan, Australia and other points in Oceania.

It marks the introduction of the Renault type of hood with this concern, the radiator being incorporated in the dash. The radiator is new, being of the French Solex type, a circular type design. A particularly neat designing job has been done with aluminum dash cowl. The cab is steel. The truck uses an improved four-cylinder motor, amidship gearbox and double chain drive.

Scarcity of Parts Serious

Truck Makers Cannot Secure Enough—Foreign Buyers Growing Factor in Trade

NEW YORK CITY, Aug. 11—The unprecedented demand for component parts of automobiles has been the dominant factor in the industry during the past week. Many makers have been held up in deliveries by failure to get some necessary part in sufficient quantities. It is not unusual for automobile passenger car makers to have a corps of road men who constantly are drumming up quicker deliveries from parts makers and who search broadcast for additional supplies in times of exigencies. This condition has invaded the motor truck field and now not a few truck makers have had to resort to the same methods of securing component parts, a most unusual situation in this field.

Big Foreign Demand

The scarcity of parts is undoubtedly due to the increased demand from foreign countries. During the past week, several jobbers from England have been in Detroit, Cleveland, Toledo, and other centers, and inquiries by mail have arrived on every steamer. One representative from France has been making the rounds during the past week. The British trade has never been in a more flourishing state so far as sales are concerned than at present, and automobiles are sold in England much faster than they can be shipped. Owing to the increased domestic demand these foreigners are finding great difficulty in obtaining cars of any kind. There is some talk among them of buying up stocks of used cars so difficult do they find it to get new cars.

A very important stage in the development of the American industry is shown by the anxiety of foreign interests to purchase motors, axles, gearsets, steering gears, etc., for assembly abroad, the feeling being that once this method of manufacture is started abroad it will continue. Parts makers are appreciating this and doing all they can to accept orders for small quantities.

Big Wheat Crop

The home trade, so far as can be learned from the distributing centers, has continued to hold throughout the vast agricultural territory, excepting where there is an immediate lull due to harvesting conditions. Continued rains add a more serious aspect to conditions. The oat crop has suffered very seriously during the past week in several States. Severe storms have injured the corn crop, but the bumper wheat crop, which promises to be the greatest in the history of the country, is looked to to carry the average, in spite of adverse weather conditions.

In engineering circles, the idea is gaining strength that the V-type of motor in eight and twelve-cylinder designs will largely displace the six-cylinder next year, so great is the demand for them and so small the trouble connected with them to date. Several of the expansions and additions to factories are rapidly getting into shape to produce these types.

Conditions in the Southwest, including New Mexico, give promise of increased business, the favorable situation in mining and other industries indicating such. For the first 7 months of this year 4230 automobile licenses were issued by Secretary of State of New Mexico, this representing a gain of 60 per cent over the corresponding period of a year ago. It is believed the percentage of increase this fall will be much larger when farmers and others begin realizing on their season's work. The greatest increase in registration and demand comes from the rural districts.

—

Cars Scarce in West—Harvesting Hay and Rye

MINNEAPOLIS, MINN., Aug. 7—The automobile business of last week in the Twin Cities was exceptionally good, considering several factors which worked against the trade. One was that farmers in Northwestern States have begun to harvest hay and rye. It is more important to the farmer and to the automobile dealer that he turn his attention just now to getting the crops in. Successful crops will pay in the fall.

Another factor was continued inability by many agencies and distributers to get cars enough to fill orders. Farmers and agents sit around the agency offices and the factory branches and refuse to move until they get cars. If three freight car loads come in, they are all gone in a trice, driven off by the waiting line.

Still another trouble was wet weather. After a long summer of cool and rainy weather the resumption by the rain god last week made roads worse, so that prospects could not get in, and somewhat dampened the ardor of other probable buyers, who turned their thoughts to something else for the time being.

The delay caused by waiting for 1916 model announcements has been overcome, according to Minneapolis dealers.

—

Signal Co. Changes Name

DETROIT, MICH., Aug. 5—The De Weese Auto Safety Signal Co. has changed its name to that of Auto Safety Signal Co. and has increased its capital stock from $1,500 to $20,000.

N. Y. Sales Ahea of 1914

Dealers Report Continued Go Business—Bad Weather Affected Some

NEW YORK CITY, Aug. 10—The l automobile dealers report large s during the last two weeks. The incl ent weather last week in some c pulled down the sales records, but tal the last week in July and the first in August together, the dealers re larger sales for that period than for same one in 1914.

Reports from Dealers

The Saxon company up to Aug sold between 1500 and 2000. Sales week were fair. Shipments are co in fast from the factory. A large centage of the sales are on the six inder car. The company is doing a business in Long Island, which sho 300 per cent increase.

The Oldsmobile company has so its cars and reports that if it had cars it could sell them. Shipment slow.

Mercer sales in July were two an half times greater than those in th responding month in 1914. Sales Aug. 10 are greater than those f whole month of August in 1914.

There is only one Stutz car o floor. Sales during the past ten have been unusually good. Even second-hand cars are sold.

Hudson sales are 300 per cent Up to May 4, the agency sold 58(During June the sales were 274 241, and up to Aug. 9, fifty-six car been sold.

All Franklin cars are sold. Th is twenty-one cars behind in ret ders. Lozier reports good sales. ments are coming in regularly. state sales are double those of Last week the rain slowed up th but during the last few days they up. Not a car on the Packar Marmon is all sold out, having demonstrator left.

—

Automobile Liability Rates Cut i

NEW YORK CITY, Aug. 10—Th mobile liability rates have been New Jersey by the New Jersey & Plate Glass Insurance Co. Th are $6.50 added to the insurabl power for cars from 16 to 30 hp to $14 under the conference co tariff rates, and all cars above 30 $14 below the conference tari above company has applied to N State for permission to write au liability and property damage.

S. A. E. Suggests Standard Names

Names of Parts Adopted at Recent Meeting—List Open for Criticism

DETROIT, MICH., Aug. 9—The suggested names for parts which have been adopted at the meeting of the nomenclature division of the standards committee of the Society of Automobile Engineers have now been announced and the committee is seeking criticism before final acceptance of the terms included. The nomenclature suggested is as follows:

Fore—toward forward end of car. Rear—toward rear end of car. (Confusion only likely in regard to dash.) Where parts are numbered No. 1 should be toward the front of the car; for instance, No. 1 cylinder is the one nearest the radiator (in conventional construction). (Note—Should valves be numbered 1 I, 1 I, 2 I, 2 E, etc., or should they be numbered 1, 2, 3, regardless of cylinder location?) Right is to the right hand when sitting in one of the seats of the car. Left—opposite. Cylinders of V type engines should be numbered 1 R, 1 L, 2 R, etc. Studs, screws and bolts shall take names from parts which they serve to hold in place, although they may be assembled with other parts, e. g., cylinder stud is permanently screwed into crankcase but holds the cylinder in place.

Engine: The name "engine" should be used rather than "motor" to avoid confusion with electric motors and secure lower freight rates. Cylinder. Cast in block—not cast en bloc. Valve cap. Exhaust valve cap. Valve chamber. Cylinder head. Cylinder head plug. Water jacket cover. Water jacket top cover gasket. Water outlet. Engine water inlet. Water jacket side (or front or rear) cover. Timing cover. Valve spring cover gasket. Valve spring cover stud. Valve stem guide. Spark plug. Priming cup. L-, T-, I-, or F-cylinders—L-head, valves on one side only. T-head, valves on opposite side only. I-head, valves in cylinder head; F-head, one valve in head, other on side.

Crankcase: Crankcase (one word). Barrel crankcase. Split type crankcase (indicating the type which is split horizontally at the center line of crankshaft). Crankcase upper half. Crankcase lower half (only used when the lower half contains bearings). Oil pan (used for lower part of split or barrel type crankcase, whether this acts as an oil reservoir or not). Oil pan baffle. "Bushing" instead of "bearing" for removable and renewable lining used in a bearing. Crankshaft front bearing cap (upper half and lower half). Crankshaft front bearing cap. Crankshaft front bearing support (sometimes used in barrel crankcase). Crankshaft rear bearing cap. Crankshaft rear (etc.) bearing cap. Crankshaft center bearing bushing (if all three bearings or if all except end ones are alike). Crankshaft second bearing, third, etc. (if more than three bearings, e. g. front bearing, second bearing, third bearing, fourth bearing, rear bearing). Inspection cover. Hand hole cover gasket. Timing gear cover. Timing gear cover gasket. Flywheel housing. Generator bracket.

Crankshaft: Crankshaft. Flywheel. Crankshaft timing gear (or sprocket). Crankshaft timing gear key. Flywheel starter gear. Flywheel starter sprocket. Flywheel studs. Starting stud. Crankshaft starting jaw.

Camshaft: Camshaft. Eccentric shaft (V engine). Camshaft timing gear. Camshaft timing gear key. Camshaft idler gear. Camshaft oil pump gear. Camshaft distributor gear.

Connecting-rod: Connecting-rod (hyphen saves confusion). Straight connecting-rod—Connecting-rod (V type engine). Connecting-rod cap. Connecting-rod bushing. Cap half (lower half). Connecting-rod cap bolt). Connecting-rod cap nut. Connecting-rod bearing shims. Connecting-rod Piston pin lock screw (in connecting-rod or piston). Piston pin. Piston boss. Piston. Piston ring. Piston groove.

Valve: Valve lifter. Valve lifter guide. Valve guide clamp. Valve lifter roller. Valve roller pin. Valve adjusting screw. Valve roller pin. Valve rocker (either at cam or at overhead valve—if both, upper and lower). Valve push rod (intermediate between lifter and valve—I-head engine). Valve adjusting screw. Exhaust valve. Inlet valve. Poppet valve. Valve spring. Valve spring retainer. Valve spring retainer lock.

Group 7-8-9: Water pump. Water pump impeller. Water pump impeller key. Water pump body (in case of doubt, body is member mounted on engine). Water pump cover. Water pump shaft. Water pump gland. (The part which contacts with the packing, whether threaded or not). Water pump gland nut (or screw, etc., where these parts are used to compress gland). Water pump shaft gear. Magneto (or generator) coupling, pump end. Magneto coupling, center member. Magneto coupling, magneto end. Tire pump driving gear. Tire pump shaft gear. Tire pump. Tire pump idler gear. Generator gear. Generator shaft. Generator coupling (members as above). Starter-generator. Gasoline pressure pump (power pump). Gasoline hand pump.

Group 10: Oil pump. Oil pump body (any type of pump). Oil pump plunger. Oil pump plunger spring. Oil pump inlet valve. Oil pump outlet valve. Oil pump shaft. Oil pump shaft gear (outside pump). Oil pumping shaft gear (inside pump). Oil pumping follower gear. Oil pump cover.

Group 11: Starting crank jaw. Starting crank shaft. Starting crank. Starting crank handle. Starting crank handle pin.

Group 12: Fan. Stationary fan support. Adjustable fan support. Fan hub. Fan blades. Fan pulley. Fan belt. Fan driving pulley.

Group 13: Inlet manifold (more than one connection to cylinder). Inlet pipe (only one connection to cylinder). Inlet manifold or pipe gaskets (at cylinders). Carburetor gasket.

Group 14: Exhaust manifold. Exhaust manifold gaskets.

$300,000 Addition for Fisk

CHICOPEE FALLS, MASS., Aug. 6—The Fisk Rubber Co. will erect a $300,000 brick and steel mill building on its new property at Oak and Grove streets, in addition to the three buildings now under construction there. The new building will be located on the property recently acquired by the company between the six-story warehouse now in process of erection and the Boston & Maine railroad track. Employment will be furnished for 3000 additional persons. The building will be five stories, with a basement 600 ft. long and 110 ft. wide.

Croxton Plant Sold to Washington Tire & Rubber Co.

WASHINGTON, PA., Aug. 7—The sale of the plant of the Croxton Motor Car Co. in the west end of the town to C. J. Davis of East Palestine, Ohio, who represents the Washington Tire & Rubber Co., tire maker, was completed yesterday. It is stated that the plant will start working before Dec. 1. About 150 men will be employed at the beginning, that number being increased later to 350. Mr. Davis will have charge of the Washington plant.

Pennsylvania Registrations $1,483,201

HARRISBURG, PA., Aug. 7—The receipts of the automobile division of the Pennsylvania State highway department for the first six months in 1915 show that $1,483,201 had been received. These receipts are the more remarkable when it is considered that on the first of July, 1912, the total receipts of the automobile division were $519,000.

Stewart Pump Supplies Cool Air

Tests Made at Armour Institute Show that Air at Tire Is at Atmospheric Temperature

CHICAGO, ILL., Aug. 9—In order to prove its contention that the statements contained in a paper presented by Paul W. Litchfield at the recent meeting of the Society of Automobile Engineers are not accurate as regards the air temperature due to the heat imparted by power pumps, the Stewart Warner Speedometer Corp. has had a series of tests made by Professor Roesch at the Armour Institute of Technology, Chicago.

The tests which were made on the Stewart motor driven pump show that the air enters the tire at virtually the same temperature as that of the outside, and furthermore, the fact is brought out that the air from a hand pump is from 30 to 40 deg. higher in temperature than the outside air. The tests were made with the Stewart pump inflating a 37 by 5 tire.

The temperature of the air was taken at three points simultaneously.

STEWART TIRE PUMP TEST

Room temperature..... 71 deg. Fahr.
Average r.p.m. of pump.....735 deg. Fahr.

Line pressure, lb. per sq. in. gage	Degrees Fahr. Temp. of air in pump	Temp. of air passing cooling coil	Temp. of air entering tire
0.00	71	71	71.0
30.25	110	76	72.0
41.00	129	84	71.5
48.00	152	88	71.0
58.25	168	94	70.5
64.00	188	98	70.0
70.00	202	103	69.5
76.00	214	107	70.0
83.00	225	110	70.0
88.00	232	114	70.0
94.00	240	116	69.5
101.00	248	117	69.0

One of the remarkable findings of this test was that the air entered the tire 2 deg. cooler than the outside air.

FOOT PUMP TEST.

Hose—24 in. of rubber hose regularly supplied with pump to gage.
Room temperature—72 deg. Fahr.

Line pressure, lb. per sq. in. gage	Temperature (degrees Fahr.) of air as it enters pump
0.00	72
25.00	74
28.50	76
36.00	78
47.00	80
55.00	82
60.25	85
66.00	87
74.00	89
79.00	92
88.00	96
93.00	99
101.00	103

The total number of strokes required with the hand pump to reach the pressure of 104 lb. was 598. It will be noted Mr. Litchfield said that, with a hand pump, there would be no particular increase of temperature, because a hand pump works so slowly. This test showed a rise of 31 deg. hotter than the outside air, due, of course, to the short length of hose connection that is furnished with hand pumps.

English Ford Sells 12,500 Cars

War Has Not Affected English Business, Which Shows 50 Per Cent Increase

NEW YORK CITY, Aug. 8—That the war has not affected the Ford company's business in England and that its 1915 output was almost 50 per cent better than in 1914, were a few interesting points brought out in an interview with P. L. D. Perry, managing director of the Ford Motor Co., Ltd., of England, who arrived in this city to-day on the St. Paul. He will make his annual business trip to Detroit. Henry Ford, together with his son, Edsil B. Ford, Frank Klingersmith, the director of the plant, and Frank Mayo, chief engineer, met Perry at the pier.

Mr. Perry denied the report that the company had received large war contracts. The company, however, is making about 15,000 cars for the British Government for use as motor ambulances.

As stated above the war has not affected the English company's business and the concern does not expect a boom after peace is declared because its factories are running at full pressure all the year round.

Mr. Perry said that the Ford factory at Manchester, England, employed 1600 hands and paid 50 per cent higher wages, grade for grade, than any other automobile concern over there.

Up to Aug. 1 this year, the company sold 12,500 cars and had 8500 on order, which included 600 ambulances that were sold to the government. The output was almost a 50 per cent increase over 1914. The engines and axles are made at Detroit and the other parts including the bodies, are made at Manchester.

The British Government sends 100 soldiers from the Army Transport Service to the Ford works for two weeks at a time to learn how to repair machines in the field and how to put them together.

The $440 car sold in the United States costs $575 in England, the extra charge being made to cover the cost of packing, insurance and transportation.

—

Britons Would Protect Motor Trade

LONDON, ENGLAND, Aug. 6—Protection against the American invasion of British motor vehicle markets is being sought by British motor vehicle manufacturers. Appeals have been made to members of parliament for either the prohibition of imports of motor vehicles or the imposition of a high import duty. They point out that owing to the absorption of the greater part of the motor output of England by the government they are unable to meet American competition; on the other hand, it is pointed out by the importers of American vehicles that British makers are now earning more than ever through war contracts and that while they are losing domestic trade to American builders their plants are running at forced draft and they are selling to a market which costs very little to secure.

British merchants who have had both motor vehicles and horses taken from them by the government are forced to adopt American vehicles to carry on commerce. The real status of the matter seems to be that British makers fear that having once used American trucks English merchants and tradesmen may continue to buy them thereafter, even though home supplies are again made available.

Ford Inventory Complete—18,500 Men Resume Work

DETROIT, MICH., Aug. 9—After having been laid off several weeks pending the taking of the annual inventory, the Ford Motor Co. resumed normal activities today when between 18,500 and 19,000 men returned to work. This return to activities of the Ford company has a far-reaching effect upon many other plants or factories which are largely working for the Ford company only. At the C. R. Wilson Body Co. it was stated that the number of men which make up the Ford department is 300 to 350 from a total force of 1300 to 1400. At the Herbert plant the force to be taken back to-day is estimated at 700 out of a normal force of 800 to 850. At both of these concerns the Ford departments will turn out touring car bodies exclusively, and both are to turn out a much larger quantity than during the past fiscal year.

—

Gramm-Bernstein Has 1,250 Foreign Truck Orders

LIMA, OHIO, Aug. 9—S. A. Gramm, vice-president and general manager of the Gramm-Bernstein Co., Lima, is authority for the statement that orders for 1,250 motor trucks are on the books of the company at this time and that considerable additonal business had to be turned down because of lack of capacity. That is being remedied, however, and additions and extensions are under way which will be completed in October of this year which will largely increase the capacity.

The company has already shipped 300 motor trucks to foreign countries, such as France, Roumania, India and Russia. A large proportion of the orders now on the books are from foreign nations.

The company is now shipping trucks at the rate of 150 per month, and when the machinery is installed in the new additions the number will be increased to 250.

Harvard Roadst for $750

Pioneer Motor Car Co. of T Brings Out 2¾ by 4½ L-Head Four

TROY, N. Y., Aug 7—The Pio Motor Car Co. of this city is puttin the market a car known as the Har which is in roadster form and equipped for $750. Minneapolis Has Clearing Ho Speed Complaints

MINNEAPOLIS, MINN., Aug. 7— ing a long series of accidents an in July a clearing house for co against violation of traffic ordin automobile drivers was formed Minneapolis Civic and Commer Some of the drivers who cause were indicted by the grand jury drivers were sentenced to the w for reckless speed and nine jitne were fined or imprisoned.

Five complaints were received by the bureau in the first hour. Twenty complaints were received the second day. Passing open street car gates within less than 10 ft., overtaking and passing street cars on the left side of the street, speeding, driving without lights, stopping on left side of street, were chief complaints. At the end of the second week none had been killed and the average of four accidents a day in July had been cut to less than one a day. One reason is better observance of rules for pedestrians issued by the committee of safety.

—

Louisville Bans Headlight Glare

LOUISVILLE, KY., Aug. 5—According to an announcement made yesterday by Mayor Buschmeyer to a committee from the Louisville Commercial Club, glaring headlights on motor vehicles must go. There is a city ordinance regulating headlights but, it is said, it has not been strictly enforced. It is expected owners will be given until Sept. 1 to eliminate objectionable features by means of ground glass shades over the upper portion of the light, or full shade with small "peep eye" in the center. After that date active steps will be taken to enforce the ordinance. Members of the Louisville Automobile Club, which has a membership of nearly 1000, have been asked to co-operate in the movement to eliminate the headlight glare danger.

—

Dim Headlights in Indianapolis?

INDIANAPOLIS, IND., Aug. 7—Mayor Bell is credited with the statement that his administration will take steps immediately to bring about the passage by the City Council of a new automobile headlight dimmer ordinance, the present ordinance having been declared invalid by Judge Deery in a recent Police Court decision. Harry E. Raitano, city prosecutor, announces that he will enter an appeal in the Marion Circuit Court from Judge Deery's decision declaring the automobile headlight dimmer ordinance invalid. Judge Deery's decision freed more than fifty automobile drivers who had been arrested in the crusade conducted by the police.

—

Committee Protests Sprinkling

NEW YORK CITY, Aug. 7—The Citizens' Traffic Committee at its meeting to-day adopted a resolution pointing out the inefficiency and danger of street sprinkling and calling on street officials to abolish it. The substitution of street washing is recommended. Street Commissioner Fetherston stated that his department was opposed to street sprinkling and only practised it in conjunction with street washing. The sprinkling complained of, he said, was done by private contractors.

Test Headlights in Bay State

Highway Commission Engineers Measure Rays, Etc., for Report on Glare

BOSTON, MASS., Aug. 9—Under the direction of the Massachusetts Highway Commission there was a series of tests of motor headlights at the Country Club, Brookline, to-night. The last Legislature directed the commission to make a report of what should be done to regulate the lights so that there would not be a blinding glare in the eyes of people and operators of other cars.

Col. W. D. Sohier and James D. Synan were present for the commission, and they had members of the engineering staff on hand to measure the rays and otherwise compile data. All the motor organizations and a number of the accessory people were present with their devices.

Colonel Sohier, who is chairman of the commission, stated that he planned to have some regulation made and then ask Governor Walsh and members of the Council to approve of it. That would make it a law, and it could be changed from time to time by the same method when it needed improvements instead of having the Legislature do it.

—

Fined $50 for Reckless Driving

HARTFORD, CONN., Aug. 9—Fifty dollars fine and thirty days in jail was the sentence imposed on two New Britain young men this week on a charge of reckless driving and attempt to evade responsibility.

—

Boys Over 16 May Work in Michigan Plants

DETROIT, MICH., Aug. 5—J. V. Cunningham, Labor Commissioner of the State of Michigan, has taken some important decisions regarding the employment of young boys in factories. This was done in reply to inquiries from manufacturers who desire to know what kind of work the commissioner considers as too dangerous or hazardous for boys. The Michigan Legislature this year amended the labor laws and now boys under 18 but over 16 may be employed for certain work in factories.

The commissioner ruled that time checking, assembling, operating a machine lathe properly guarded, ordinary bench work, sheet metal work in automobile plants are not considered dangerous.

Power punch presses automatically operated and properly guarded, not requiring the operator to come in contact with the die, are considered safe, but power punch presses operated by foot or hand are considered dangerous. Boys may not adjust a die. Gang drill presses, wood working or wood turning lathes on account of speed and edged tools are considered dangerous and not to be handled by boys.

Automatic screw machines having belt shifter with belts, pulleys and gears properly guarded are considered safe.

—

Cal. License Fees Reduced One-Half

LOS ANGELES, CAL., Aug. 6—Commencing Aug. 1 automobile license fees in the State of California were reduced 50 per cent, under the law which wisely holds that the remaining five months of 1915 should not be paid for at the full yearly rate.

The Southern California branch of the State motor department is now located in the new Union League Building at Second and Hill Streets, Los Angeles, in charge of Superintendent W. S. Goble.

—

N. Y. Sightseeing Ordinance Vetoed

NEW YORK CITY, Aug. 9—Mayor Mitchel has vetoed the proposed ordinance that sightseeing cars might stand in front of a building where the owners have an office, if the consent of the police commissioner and the owner of the building has been secured. The Mayor stated that this would permit cars to sand at all times in front of the building. This is, in effect, the maintenance of a private stand where others may be excluded.

—

To Fight Baltimore Ruling

BALTIMORE, MD., Aug. 7—Members of the Automobile Club of Maryland are preparing to fight the ruling which places automobiles under the same ordinance as wagons in that they cannot remain standing on the street more than 2 hr. at a time. This will mean that all the parking places about the city will have to be abolished. The police department has announced that it will begin to enforce the law on Sept. 15.

—

Garage Men Planning State Organization

COLUMBUS, OHIO, Aug. 9—The Columbus Garage Owners, Asso. has arranged for a State convention of garage owners, to be held at Columbus, Ohio, Oct. 4, 5 and 6. The plan is to organize a strong State association for the benefit of garage men and tire repairers. A convention committee to arrange for the meeting consists of F. E. Avery, chairman, Robert T. McClure, secretary, and George McDonald, treasurer.

Notices have been sent out to 2000 garage men of the State inviting them to attend the meeting and to give their views of the question of forming a State organization.

Zenith Far Ahead of 1914

Last Year's Total Business Already Surpassed—10,000 Carbureters Monthly Output

DETROIT, MICH., Aug. 9—With two months still to go before the end of its fiscal year, the Zenith Carbureter Co. has already passed its total production of 1914. Business has been steadily increasing since January, and at the present time the monthly output averages 10,000 carbureters. Prospects are the best the company ever experienced and the outlook for 1916 is that it will be another record-breaking year.

The business increase has not been confined to any special type of carbureter, neither has it been exclusively in the passenger car field, but it has also increased considerably in the motor truck field. A reinforced concrete addition is being erected which will give the company much needed additional floor space.

—

To Make Bullet-Proof Tires

SOUTH BEND, IND., Aug. 9—The Zeglen Tire & Fabric Co. has been organized in this city to manufacture automobile tires from the Zeglen bullet-proof fabric invented some years ago by Casmir Zeglen. Headquarters of the company will be established in this city. The elimination of all the tire troubles which the average motorist experiences is promised by the backers of the concern. The cost of tires manufactured from the Zeglen fabric will be only 10 per cent greater than that of the average tire, it is said. It is planned to manufacture tire casings here and dispose of them to tire manufacturers. Some of the advantages claimed for the new tires are: freedom from cuts, punctures and stone bruises, elimination of blow-outs and prevention of bulging and rim cutting. In addition to the tire fabric the concern plans the manufacture of protectors for ordinary pneumatic tires; these will serve as guards for inner tubes.

Mr. Zeglen won considerable prominence some time ago by the invention of a bullet-proof coat.

—

Oakes Capital Now $75,000

INDIANAPOLIS, IND., Aug. 11—The Oakes Co., this city, has increased its capital $50,000 to $75,000. The officers of the company remain the same.

—

To Push Ampco Bronze for Bearings—Capital Increased

MILWAUKEE, WIS., Aug. 7—The American Metal Products Co., Thirtieth Street and Lisbon Avenue, Milwaukee, Wis., which recently announced the perfection of a new metal alloy known as Ampco bronze, the invention of A. Littmann, is now making a campaign in the automobile and garage industry for the use of the alloy for high-speed bearings. Twenty Milwaukee garages, repair shops and machinery and supply companies have been appointed agents and in addition to marketing the bronze for initial use, emphasis is laid upon its use for replacement of bearings. The company has increased its capital stock from $25,000 to $100,000 to accommodate the increased production and trade.

—

Few Market Changes

NEW YORK CITY, Aug. 10—The markets for the past week made very few changes, there were but a few gains and very heavy losses. The heaviest loss occurred on Wednesday when open-hearth steel dropped from $25 to $22.50, a total drop of $2.50. The rest of the steel markets made no changes.

The lead was also a bit unsteady when during the first part of the week it rose from $4.75 to $5.00 and then made a considerable drop on Monday of 37½ cents. Copper declined when leading interests quoted 18 cents but round lots were at 17¾ cents, the cause being another severe break in London. While this reduction was noted in some quarters on Saturday, the cut to 18 cents became general yesterday. In the open market the metal was offered at 17⅞ cents with no buyers. The cotton oil market was dormant yesterday with trading being so light that there was scarcely any market at all. There were no changes in the oil and lubricant markets.

—

Elmira Truck Projected

ELMIRA, N. Y., Aug. 7—Organization of the Elmira Commercial Motor Car Co. has been completed. The concern has been incorporated in New York with a $500,000 capital. The plan is to produce a vehicle of 500-lb. capacity to sell at $300, after the designs of W. H. Ives of the defunct Ives Motorcycle Corp., Owego, N. Y.

—

Detroit Forging Business a Third Larger

DETROIT, MICH., Aug. 9—During the fiscal year of the Detroit Forging Co. which ended Aug. 1, this company did one-third more business than during its previous business year. Manufacturers have been ordering much earlier than last year and all have greatly increased their orders. One of the largest orders ever received by the company was taken a few days ago being for 2,000,000 forgings, valued at over $75,000.

—

Guelph Tire & Rubber Elects

GUELPH, ONT., Aug. 7—Several citizens of Berlin were present at a large and enthusiastic meeting of the shareholders of the Independent Tire Co., now known as the Guelph Tire & Rubber Co. This was the first meeting since the liquidation and the reorganization of the company. The provisional directors retired and the first board of directors was elected, which consisted of Messrs. J. E. Carter, Guelph; D. McIntosh, Guelph; L. Kaufman, Ohio; H. L. Davidson, Southampton; R. Dunn Wellesley and Dr. Winning, London, Ont.

—

Safety-First Convention Oct. 19-20

NEW YORK CITY, Aug. 7—The date for the first annual convention of the Safety-First Federation of America to be held in Detroit, has been set for Tuesday and Wednesday, Oct. 19 and 20. The program has not as yet been prepared.

Takes Over Mason Stock

FLINT, MICH., Aug. 6—Complete linking of the Mason Motor Co. with the Chevrolet Motor Co., Flint, Mich., has been accomplished by the taking over of the remainder of the Mason stock by the Chevrolet company.

At the same time that the stock transfer was completed ground was broken for an addition to the Mason factories and twenty more acres of ground were secured on three sides of the Chevrolet plant.

—

Daly Resigns from King Co.

DETROIT, MICH., Aug. 6—W. L. Daly, sales manager of the King Motor Car Co., has resigned and after a short rest will enter into an individual venture of his own. R. P. Bishop, assistant to Mr. Daly, succeeds him. I. B. Meers enters the position formerly held by Bishop.

—

Dividends Declared

Maxwell Motor Co., quarterly of 1¾ per cent on first preferred together with an additional dividend of ¾ of 1 per cent on the stock, payable Oct. 1.

Studebaker Corp., quarterly of 1¾ per cent on preferred and 1¼ per cent on the outstanding common, payable Sept. 1.

B. F. Goodrich Co., 1¾ per cent on preferred, payable Oct. 1.

Standard Oil Co. of California dividend payable Sept. 15 to stockholders of record Aug. 20.

Security Prices Higher

Sturdy Demand in All Stocks —General Motors Makes High Record

NEW YORK CITY, Aug. 9—Except for a few fractional declines, most of the stocks that changed made substantial gains in this week's security quotations. Resistance to all disquieting influences with a consequent active market, strong tone and higher prices, were the dominant feature. At the beginning of the week there was an upward rush. After this a selling movement of considerable moment set in. Some of the issues again displayed advances similar to those which were so frequent in April and May.

Changes this week ranged from gains of one-quarter to twenty-four points and loses from one-quarter to three points. General Motors common featured the market with a twenty-four-point rise, closing at 203, at an absolute high record. The strength of this issue was attributed to expectation of early dividend action. It is stated that the company will have a net profit for the fiscal period of $20,000,000 meaning a balance for the common of nearly 60 per cent. Willys-Overland common also reached a high price level with a gain of ten and one-half points.

Tire issues showed gains, though not as high as usual. B. F. Goodrich common went up one-quarter point, while that of the preferred rose a half-point. Kelly-Springfield first preferred rose three-fourths of a point, while that of Swinehart and U. S. Rubber rose two points. The rest of the tire issues remained unchanged. The Detroit issues showed very large substantial gains, ranging from one to seventy-five points, with losses slight from one-fourth to ten points.

—

Paine President Detroit Commercial Co.

DETROIT, MICH., Aug. 7—W. D. Paine, who was supervisor of sales of zone 4 of the Maxwell Motor Co., has resigned to become president and sales manager of the Detroit Commercial Co. Mr. Paine was with the Maxwell company since its organization. He also was formerly with the Studebaker Corp. and the E-M-F company.

—

Cooper Maxwell Supervisor

DETROIT, MICH., Aug. 7—L. K. Cooper has been appointed supervisor of sales in zone 4, by the Maxwell Motor Co., taking the place of W. D. Paine, who resigned. Mr. Cooper has been with the Maxwell organization since its inception and was on special duty in Chicago during the past season. Now his headquarters will be Detroit and his territory stretches from the Great Lakes to the Gulf of Mexico and includes auxiliary offices in Indianapolis, Ind., and Memphis, Tenn. It was Mr. Cooper who won the first prize, $500, in the Maxwell sales competition of the past season.

—

Ollier Studebaker Director

DETROIT, MICH., Aug 7—L. J. Ollier, sales manager of the Studebaker Corp., has been named a director of that organization.

10,000 Farmers at Tractor Test

May Make Illinois Demonstration a Yearly Affair—Many Sales—Lectures Given

CHAMPAIGN, ILL., Aug. 7—Ten thousand farmers and others interested attended the first Illinois tractor demonstration upon a spacious tract 5 miles south of this city last week. Four days were selected for the exhibition, but the opening days were marked by rain which limited the show to the two closing days, Thursday and Friday. Despite the weather handicap, the demonstration was voted a great success. Due to the proximity of the University of Illinois here, and its well-known attraction for all followers of agriculture, Champaign was the choice of the visitors as the permanent location of the annual exhibit, and it is believed that definite arrangements will be made later for the second demonstration some time in August of 1916. It was suggested that all farm implements be exhibited in conjunction in order to increase the interest and attract the farmers, but the tractor representatives and editors of the farm journals in attendance were opposed to this, and it is likely that in all future events the attractions will be limited to tractors. The demonstration given last week was not a contest and no prizes were awarded.

Conditions of Tests Uniform

To this end all fuel used was of the same grade, the depth of plowing and engine speed regulated, and every effort made to make the demonstration a real showing of what the machines can do in farm work. The mornings were devoted to private demonstrations at which the manufacturers were given considerable latitude in the kinds of work performed. The formal demonstration took place in the afternoon. Each machine was allotted a strip of ground for plowing in accordance with the rules of the field manager. The following is the list of exhibitors: Avery Co., Peoria, Ill.; Bates Tractor Co., Lansing, Mich.; Bull Tractor Co., Minneapolis, Minn.; Bullock Tractor Co., Chicago, Ill.; J. I. Case Co. (Wallis tractor), Racine, Wis.; Corn Belt Tractor Co., Minneapolis, Minn.; Dayton Dick Co. (Leader tractor), Quincy, Ill.; Dauch Mfg. Co., Sandusky, Ohio; Denning Motor Implement Co., Cedar Rapids, Iowa; Electric Wheel Co., Quincy, Ill.; Emerson, Brantingham Co., Rockford, Ill.; Ford Tractor Co., Minneapolis, Minn.; Harrt-Parr Co., Charles City, Iowa; Heider Mfg. Co., Carroll, Iowa; Hoke Mfg. Co., South Bend, Ind.; Holt Mfg. Co., Peoria, Ill.; Huber Mfg. Co., Marion, Ohio; Hume Tractor Co., Hume, Ill.; International Harvester Co., Chicago, Ill.; Joliet Oil Tractor Co., Joliet, Ill.; Kinnard-Haines Co., Minneapolis, Minn.; Lawter Tractor Co., St. Marys, Ohio; Lion Tractor Co., Minneapolis, Minn.; Parrett Mfg. Co., Chicago, Ill.; Peoria Tractor Co., Peoria, Ill.; Sweeney Tractor Co., Kansas City, Mo.; Steel King Tractor Co., Detroit, Mich.; Universal Tractor Co., Columbus, Ohio; Waite Tractor Co., Chicago, Ill., and Waterloo Gasoline Engine Co., Waterloo, Iowa.

The climax to the demonstration came on Friday when thirty-two engines, pulling from two to six plows, went along side by side in a stubble field 110 acres in extent. The larger type of machine, built to pull eight plows of 14-in. bottoms, and the smaller type, with but two plows connected, worked side by side and the farmers were able to note the advantages of each. Turning under 3-ft. rag weeds in ground that had not been touched by a plow for many years was a severe test for the tractors, and some had all that they could do. A 40-acre field of sod was plowed up in quick time. It was observed by many of the farmers that tractors which had been prime favorites on the exhibition lot were not so popular after the plowing tests started, while others that had been regarded as freaks were able to give a better account of themselves than their more pretentious neighbors. Some small outfits that had been regarded as toys were able to demonstrate that they were real tractors in plowing, while some of the huge machines found considerable trouble in handling the weed problem. Many farmers who came doubters returned home purchasers. "I like your tractor but I cannot afford it," remarked one farmer to a tractor salesman. "How many horses will it take to do the work of this machine upon your farm," asked the salesman. "Seven," was the reply. "At $150 each, they are worth $1,050, while my machine sells for less than $1,000," was the agent's observation. The farmer saw the point and placed his order. Several hundred sales were reported as a result of the exhibition, and all companies represented were well pleased over the results. Incidental to the demonstration there were evening programs of lectures. C. O. Reed of the University of Illinois spoke upon the subject of adjusting and operating plows. F. I. Mann of Gilman told of plowing and tillage from the farmers' standpoint. Prof. I. W. Dickerson of the University of Illinois answered in the affirmative the question, Shall I buy a Tractor? Raymond Olney gave a lecture on tractor operation with moving pictures in conjunction. Prof. F. M. White of the University of Wisconsin gave a talk upon traction economies.

P. O. Truck Bi Open Sept. 8

Five or More Each of ½-T to 3-Ton Vehicles to Be Purchased

WASHINGTON, D. C., Aug. 10—*Sp Telegram*—On Sept. 8 the post office partment will open bids for furnis and delivering from time to time as may be required during the next f year for use in the postal service, following gasoline motor trucks: Fi more of ½-ton capacity; five or mo ¾-ton capacity; five or more of 1½ capacity; five or more of 3-ton capa Proposal blanks, specifications and prints will be furnished upon ap tion to the purchasing agent of the office department.

Chemicals High-Batteries Hi

NEW YORK CITY, Aug. 11—Bat are selling at 35 cents, compared 25 cents a short time ago. The mat used in the construction of the coil advanced enormously, due to the w

Manganese, the shortage of whic affected the steel trade, is one of th ingredients of the dry cell, the being ammonium chloride, the c rod and the zinc case. The mang dioxide used in the cells is now for $120 a ton, compared with $25 a ton before the war closed the I nelles and cut off supplies from the Sea, which formerly furnished th of the ore used here.

The advance in zinc, or spelte also boosted the price of dry cell high as 32 cents has been paid grades of spelter used in makir batteries.

Ammonium chloride was forme ported, largely from England an many, in considerable quanties and 6 cents a pound. Domestic facturers are now turning out thi ical at about 7½ cents a pound, ar is apparently no danger of a sho

Velie Sells 600 War Tru

MOLINE, ILL., Aug. 7—The V gineering Co. of this city has a contract from the French Go for 600 light trucks. The st is that 275 vehicles on the order deivered at New York by Jan.

Truck Ousts Mail Car

BOSTON, MASS., Aug. 7—Mot have been substituted for tr in the handling of mail betwee eral post office and sub-statio Boston postal district. A c known as the Boston Mail De

has been organized with a capital of $50,000 to carry out a two-year contract with the government, beginning Aug. 15.

There are fifteen 3000-lb. trucks, all of General Vehicle Co., manufacture, being of a pattern similar to the sixty-eight electric trucks which handle the mails in New York City.

The runs into the Boston suburbs vary from 15 to 24 miles in length, with numerous stops at the various sub-stations. Cars will be garaged and cared for at the Boston Edison Co.'s electric garage on Atlantic Avenue.

—

Allis-Chalmers Tractors for Russia

MILWAUKEE, WIS., Aug. 7—An order for a number of new tractor trucks produced by the Allis-Chalmers Mfg. Co. has been received from Russia. These trucks are different from the ordinary commercial vehicle in that they are fitted with creeping or track laying traction devices in place of the rear wheels and the front axles are pivoted at the center to allow them to negotiate rough roads. They have steel tires in front and have steel track in the rear.

—

French Contract Rumor Denied

NEW YORK CITY, Aug. 9—A report published in a New York daily purporting to be a cable dispatch from Paris stating that J. P. Morgan & Co. had negotiated a contract with the French Government for the entire motor truck output of the Packard, White and Pierce-Arrow companies for an indefinite period. Charles Clifton, treasurer of the Pierce-Arrow Motor Car Co., Buffalo, N. Y., C. R. Norton, truck sales manager of the Packard Motor Car Co., Detroit, and J. A. Harris, Jr., advertising manager of the White Co., Cleveland, have denied that any such contract has been made or that they have any knowledge of negotiations for same. This strongly brings out the fact that the country is not contemplating any purchase of the very desirable and perishable domestic trade.

—

May Register Tractors in Kansas

TOPEKA, KAN., Aug. 5—The tremendous publicity given the tractors in Kansas during the past few weeks has aroused for the interest of Mr. Curt Myers in having an automobile registration department in the office of J. T. Botkin, Secretary of State. Mr. Myers expressed himself as of the opinion that tractors should pay a license registration fee the same as automobiles, since they are harder on the paving of roads than the rubber-tired cars. It is likely that legislation providing for the registration of tractors may be introduced at the next session.

75,000 Cars for Wisconsin

20,000 More Cars Registered on August 1 Than in Whole Year 1914

MILWAUKEE, WIS., Aug. 9—Wisconsin's motor car registration on Aug. 1 reached approximately 20,000 more than the entire registry for the year 1914. There is no question now that the total registration for 1915 will exceed 75,000, the estimate made in these columns at the beginning of the year. The comparative figures on Aug. 1 were:

	Aug. 1, 1914	Aug. 1, 1915
Motor cars	48,000	73,100
Motorcycles	7,100	8,045
Dealers	1,150	1,520

It will be seen that not only have private registrations increased enormously, but the number of dealers is much larger. The registration of dealers for 1914 showed a loss of about 350 compared with the 1913 total.

A. J. Cobban, motor registry clerk in the Secretary of State's office at Madison, says that applications continue at the rate of about 200 a day and figures that the 75,000 mark will be reached before Aug. 31. Instead of being spotty as in former years, this year's registrations are uniformly maintained from month to month, indicating a greater stability and soundness in motor car buying by the people of Wisconsin.

—

Kansas Registrations Amount to $48,959

TOPEKA, KAN., Aug. 6—The reports of W. E. Davis, State Auditor, show that for the year ending June 30 the State received as its share of the motor car and motor cycle license fees $48,959.25; last year the sum was $30,702; the State receives 75 cents of each $5 paid for a motor car license and 50 cents of each $2 paid for a motor cycle license. The bulk of the money goes into the road fund of the county issuing the license. During July of 1915 the State received $23,733.25; July receipts, 1914, were $8,267. Sedgwick county paid the largest sum during the year, $2,736.50; Reno county, $1,760.50; Shawnee county (in which is Topeka), $1,566.25.

—

One Car to Every 15 Persons in Pomona

POMONA, CAL., Aug. 3—Deputy Assessor C. W. Talbott of this city allows one motor car to every fifteen citizens and estimates that one-fourth of the families living in Pomona own automobiles. His report shows that there are 825 machines here and that they represent an original expenditure of more than $500,000, although the 1915 assessed valuation is $165,000. The total amount of tax collected on automobiles in Pomona this year will be $2,700 or about 2 per cent of the entire tax collections of the city. The deputy assessor estimates that $10,000 is the sum that was paid this year for State licenses. The State and county taxes amount to $3,300 and the city taxes $2,700 bringing the total expense of owning cars up to $16,000 for the year. Fifty cars have been purchased since the assessor closed his books.

—

Maryland Business Lines Must Maintain Reserve Equipment

WASHINGTON, D. C., Aug. 7—The Maryland Public Service Commission has issued a set of rules governing the operation of various motorbus lines in the State. An important regulation is that requiring all owners of such services to maintain sufficient reserve equipment in good operating condition. In the opinion of some this rule is construed as an intention on the part of the commission to require the acquirement of additional cars which at all times must be held in reserve in case of a breakdown of the regular cars.

The new rules require that all motor vehicles used in the transportation of passengers or freight within the State for service charge shall be under the jurisdiction of the commission, the same as other common carriers. All such vehicles must be registered with the commission and upon registration the owners will be furnished with identification cards for each vehicle, whether held in reserve or otherwise. The commission reserves the right to arrange or rearrange the routes and schedules so as to prevent congestion on the highways.

—

Oklahoma Registration, $50,000

OKLAHOMA CITY, OKLA., Aug. 7—Approximately $50,000 was received by the State highway fund up to Aug. 1 from licenses issued to automobiles by the State Highway Commissioner, from the time the new law went into effect. This sum was derived from approximately 7500 automobiles. The money derived from the taxation of automobiles by the State is to be returned to the counties.

—

Van Speedometer Contracts

ELGIN, ILL., Aug. 7—The Van Sicklen Co., which has new general offices in this city, has closed contracts with the manufacturers of the Marmon, Monarch and the new Detroiter for the Van speedometer as standard equipment for the coming year.

—

$1,000,000 Tire Co. Formed

DOVER, DEL., Aug. 10—The Perfection Tire Sales Co., to deal in all kinds of tires, has been incorporated, its capital being $1,000,000. F. J. Handel, L. B. Bautz, and M. M. Bennett of Buffalo, are the incorporators.

Astor Cup to Open Sheepshead

Vincent Astor Offers Perpetual Trophy—American Cup Later—Rush Work

NEW YORK CITY, Aug. 9—When the Sheepshead Bay Speedway opens on Oct. 2 the 350-mile inaugural race will be for a perpetual automobile trophy which was offered yesterday by Vincent Astor, the event to be known as the Vincent Astor Cup race. Originally it was intended to have the first race known as the American Cup Race, but with the offering of the Astor Cup it was decided to make this the first race over the Speedway, and the American Cup race will be contested at a later date.

Good progress is being made on the Sheepshead 2-mile board speedway and it is expected that the board surface on which the cars will run will be finished Aug. 20, and the grandstand Sept. 10. The protective walls on the outside of the track and on the inside of the safety apron are more than half completed. Tunnels for six lines of automobiles are being excavated and the concreting of these has begun. One of the small passenger tunnels has been completed. The main grandstand, which is a two-story steel affair, will be 1300 ft. long, and 600 ft. of the double deck structure has already been completed. About 1000 ft. of the open wood bleachers on the back stretch are completed.

—

850-Mile Reliability Run through Rockies Sept. 6

DENVER, COL., Aug. 7—An 850-mile sanctioned reliability and economy run of six days through the Rockies in Colorado is scheduled to start from Denver on Sept. 6.

The run will follow the Midland trail directly west from Denver by way of Golden, Lookout mountain, Idaho Springs, Barthoud pass, Hot Sulphur Springs and Kremmling, where the route will swing over the new Rabbit Ear pass road now being completed by the United States Forest Service into Steamboat Springs. The second day will be from Steamboat Springs to Craig over the northern branch of the Midland trail, and thence south through the wild fishing and big game country to Meeker, from where it will follow a link of the Pike's Peak Ocean to Ocean highway to Rifle and Glenwood Springs. The third day's run will be over the main line of the Midland trail to Grand Junction, near the Utah line. The fourth will start the return eastward over the Rainbow route through Delta, Montrose, Gunnison and over Monarch pass to Salida. The fifth will continue on the same road through the Royal Gorge to Canon City and Florence, and the sixth return to Denver by way of Pueblo and Colorado Springs over the Gulf-National Parks highway.

The trip will take in some of the grandest scenery to be found anywhere, and is counted upon to make a widely-felt demonstration of the feasibility of motoring over Colorado's picturesque roads through the mountains.

—

$500,000 Speedway for St. Louis

ST. LOUIS, MO., Aug. 7—Initial steps toward raising a $500,000 fund for the building of an automobile speedway and grandstand at Maxwellton, St. Louis County, were taken here this week. Part of the half million dollar fund has been raised and it is not improbable that construction will be begun soon. The details of the project will be made public following another meeting next week.

Maxwellton at present has an excellent mile dirt track and a large wooden grandstand.

—

Show Announcements

MILWAUKEE, WIS., Aug. 9—An automobile show will be held in this city, Sept. 13 to 17, when the Milwaukee Automobile Dealers, Inc., will conduct the exposition at the State fair grounds during the State fair week. Machinery Hall will be used exclusively for the show.

VENTURA, CAL., Aug. 9—An automobile show is to be a feature of the annual county fair which is scheduled to open here Aug. 26. There are to be more than seventy-five automobiles on exhibition. The automobile exhibits are to be located in a large tent, 100 by 210, placed on the half-mile race track.

—

Denver's Show Plans Progressing

DENVEP, COL., Aug. 9—Entries for the automobile and accessory display planned by the Automobile Trades Asso. of Colorado for the two weeks of the International Soil Products Congress in Denver, Sept. 27 to Oct. 9, are now being solicited by a special committee from the association, and the outlook is favorable for a large representation. Five dealers have already contracted for space, and twice that many more have practically pledged themselves to sign up at an early date. Trade conditions in Colorado and neighboring States in the Rocky Mountain territory are exceptionally good this year, and the show is counted upon to draw attendance from a wide district, especially on account of being held in conjunction with the farming congress, an annual feature.

Rush Twin City Speedway

Working Force Tripled—To Finish by Aug. 15—10,000 Seats Sold in Block

MINNEAPOLIS, MINN., Aug. 9—With the cessation of rain the working force at the Twin City Speedway has been tripled and work is to be finished by Aug. 15. One entire grandstand, nearly 10,000 seats, was sold entire to St. Paul, Aug. 7. Every drug store keeper in Minnesota, the Dakotas, Montana and parts of Iowa have been enlisted in selling seats. Placards and newspaper advertising in every county in Minnesota refer ticket buyers to the druggists. Five hundred militia men have been reserved to police the speedway on Sept. 4.

W. W. Brown, dirt track driver in a Du Chesneau, filed entry Aug. 6.

A cup has been offered by the Speedway for touring clubs. Number of miles traveled, multiplied by cars taking part, gives the score.

The War Department has approved the plan to extend the street railway through the reservation at Fort Snelling to the Speedway. This will give transportation for thousands of persons.

—

100-Mile Invitation Race for Indianapolis Oct. 9

INDIANAPOLIS, IND., Aug. 10—The Indianapolis Motor Speedway has to-day been granted a sanction for a 100-mile invitation race to be held on the speedway here Oct. 9. Six cars will start, the piston displacement maximum being 300 cu. in. It is understood that $10,000 in cash prizes will be awarded.

—

Ricker Indiana A. A. A. Representative

INDIANAPOLIS, IND., Aug. 7—Charles W. Sedwick, who has been the Indiana representative of the American Automobile Association since 1908, has resigned and Chester Ricker has been appointed to fill the vacancy.

—

May Stage Corona Road Race Oct. 1

CORONA, CAL., Aug. 5—There is to be a Corona road race this coming fall, according to prominent business men of the city. A committee has already been appointed to place the stock to guarantee the $15,000 purse and in lots of from one to five shares, more than half of the race stock has been sold within four days. The stock is selling at $50 per share, with one-half down and personal notes for the balance. No stock is being sold outside of Corona and no one person is allowed to purchase more

than five shares. It is certain that the race will not be held on Thanksgiving Day. It is proposed to hold the race about Oct. 1 and the Corona classic will be the only road race held in Southern California this season, if the "Desert Classic" is not revived, which is hardly probable.

—

150-Mile Race for Fresno

FRESNO, CAL., Aug. 5—Plans are rapidly being completed for the staging of a 150-mile race for a $5,000 purse on the 1-mile dirt track of the Fresno County Agricultural Assn., Oct. 2. This will close the district fair here which is an annual five-day event. The grandstand has a seating capacity of 30,000 and the drivers will be in full view of the spectators at all times.

L. A. Nares will referee and the judging will be done by W. E. Drury, Bakersfield; W. L. Hughson, San Francisco; L. S. Upson, Sacramento; John R. Graham, Merced; H. C. Carr, Porterville; S. C. Walker, Visalia. Mr. Grimes, from Hanford, will act as timer. The event is sanctioned by the contest board of the A. A. A.

—

Maxwell Dealers Attend Announcement Banquet

LOS ANGELES, CAL., Aug. 4—The annual announcement banquet, given by the Laird Motor Car Co., southern California and Arizona distributors for the Maxwell line to their dealers from all over the territory, was held in the big banquet room of the Los Angeles Athletic Club, last Thursday night. The new 1916 Maxwell was displayed in Los Angeles for the first time on that day. C. J. Toner of the Maxwell Motor Co. outlined the policy and plans for the 1916 season after the dinner. There were fifty-three Maxwell dealers and officials present, representing practically every city in Arizona and southern California.

—

I. V. A. Convention Oct. 18-19

NEW YORK CITY, Aug. 7—The sixth annual convention of the Electric Vehicle Assn. of America has been scheduled for Monday and Tuesday, Oct. 18 and 19 at the Hotel Statler, Cleveland, Ohio. The decision to limit the convention to two days was arrived at on the occasion of the organization meeting of the convention held in Cleveland, July 19. The short period of the convention was determined upon owing to the other conventions which will occur in the fall and to the fact that it was deemed advisable to have a concentrated program consisting of real business rather than a longer and more social one, as busy men will be more likely to attend such a convention. Others have not as yet been announced.

Thomas and Bablot Are Free

Two Famous Drivers Not in Army Service—Six French Cars Are Available

PARIS, FRANCE, July 28—France is still able to lend some assistance to America in the way of furnishing racing drivers and racing cars. At present two drivers of international reputation are free from army service, these being Thomas, winner of the 1914 Indianapolis race, and Bablot, who has had international reputation. Cars available are three Delages, and one each of Schneider, Alda and Nagant. The following drivers are not available as they are doing army duty: Goux, Boillot, Guyot, Chassagne, Duray, Hemery, Rigal and Wagner.

If America expects to secure any of these cars for its speedway meets it will be necessary to buy them outright.

—

New Co. in Cleveland

CLEVELAND, OHIO, July 31—Negotiations are about to be completed here for purchase of a site on the East Side for the erection of a plant for the manufacture of a new car to be built on the lines of a motor boat. The names of the new

An acre and a half with long-time options on additional ground for plant enlargement comprise the site where building is to begin as soon as the details have been worked out. Plans for the factory have been prepared, it is reported, by the National Engineering Co., this city, and the structure will contain about 25,000 sq. ft. of floor space. Equipment will cost $25,000 and the factory site $10,000.

—

Baltimore's Jitney Fight in Court Starts

BALTIMORE, MD., Aug. 7.—The legal test of the new ordinance governing the jitney bus in Baltimore has started. Those fighting to have the new law declared unconstitutional claim that the tax of $25 a seat per year is burdensome. The case is being heard by Judge Elliott. As it stands at present, the city has been restrained from putting the new law into operation.

—

Philadelphia Jitneys Receive Death Blow

PHILADELPHIA, PA., Aug. 7—The deathknell of the jitneys in this city was sounded to-day when, on the application of City Solicitor Ryan, Judge Sulzberger, of Common Pleas Court No. 2, vacated the temporary injunction which he had granted the Jitney Auto Service Co. on July 15 restraining the municipal authorities from enforcing the City Councils' drastic regulation of operation of jitneys over the city streets.

The failure of several jitney associations to sink personal animosities and petty jealousies was the cause of their undoing. The men failed to file the $2,500 bond designated in the Court's restraining order.

As the ordinance which will now go into effect requires the filing of individual bonds of $2,500 by each driver, officers of the associations admitted tonight that as the car owners in their aggregate capacity were unable to do so it was highly improbable that as individuals they would be able to do it.

—

Baltimore Trolley Co. Enters Jitney-Bus Field

BALTIMORE, MD., July 24—The United Railways & Electric Co., of Baltimore, which has been hard hit by the jitney business in this city, has entered the field and is running a number of buses. The new company is the Baltimore Transit Co., and has been incorporated with a capital stock of $100,000. President William A. House, of the United, admits that the company is backed by the railway. William H. McKee of Philadelphia, is manager of the transit company.

President House says the railway's interest in this service is due to its desire to see a bona fide effort made to ascertain whether or not the jitney means of transportation is a desirable supplement to the present methods and the United's future action will depend upon this demonstration.

—

Indiana Service Managers Organize

RICHMOND, IND., Aug. 7—A movement has been started to organize the service managers of the automobile manufacturing concerns in Indiana into an association to be known as the Organization of Service Managers in the State of Indiana. Twenty companies will be represented at the monthly meetings according to C. J. Elston, service manager of the Westcott Motor Car Co. of this city. The first meeting will be held to-day.

—

Mercer Uses Houdaille Absorber

NEW YORK CITY, Aug. 9—Clodio & Engs, Inc., United States representatives of the Houdaille shock absorber, have received an order from the Mercer Automobile Co., Trenton, N. J., for Houdaille equipment on its 1916 production. The firm has started the manufacture of this article here, and it will now be standard in the American market.

—

Safety Isles in Duluth Successful

DULUTH, MINN., Aug. 9—Aisles of safety for pedestrians, "no parking" zones, whistle signals for traffic policemen, and near stops for street cars have been inaugurated this week

Packard Has New Machinery

Entire Factory Equipment Revised for Making Twin Six —Express Shipments

DETROIT, MICH., Aug. 5—Although new machinery and special tools are coming almost daily to the plant of the Packard Motor Car Co. to provide for the practically entire new equipment necessary in making the Twin-Six, the officials of the company have on several occasions lately gone to extra big expense in order to get, with the least possible delay, some machines which were needed more than others. Not long ago, because the railroad company could not guarantee fast delivery of a special milling machine to be shipped from Worcester, Mass., vice-president of manufacturing F. F. Beall, chartered a locomotive for the purpose of thus bringing the machine at once to Detroit. A double-end drilling machine was shipped in the same way from Springfield, Mass., a special transmission boring machine, weighing nearly one ton, was shipped by express from Worcester, and shipments of bar steel were made the same way at express rates.

—

Kline Co. Acquires Property

RICHMOND, VA., Aug. 9—The Kline Car Corp. has acquired the property of the old Kline Motor Car Corp. for $15,000. The property is situated just outside the city limits and contains 14,167 acres.

All buildings, machinery, franchise rights and the right to use the name "Kline Car" are included in the property transferred.

—

Rands Mfg. Co. Adds

DETROIT, MICH., Aug. 9—A two-story addition 153 by 65 is now under construction at the plant of the Rands Mfg. Co. and will nearly double the windshield department. The building will cost about $26,000. An increase in business of at least 50 per cent since the first of the year is reported by this concern, which makes tops and windshields on contract work only. Day and night shifts are at work, the total number of men now on the pay roll being about 650.

—

Takes Over Keeton Plant

DETROIT, MICH., Aug. 9.—The Detroit Metal Refining Co., a new corporation, has taken over the old Keeton factory in Detroit and converted it into a modern and up-to-date smelting plant.

Sol Sadek, for years general manager of the Progressive Metal & Refining Co. of Milwaukee, will direct the business of the new company and make his future residence in Detroit. He will, however, retain his interests in the Progressive company.

The Keeton plant has been entirely renovated to accommodate the demands of the new tenant, its two and one-half acres of buildings being fitted with the most modern equipment. This includes forty-eight furnaces, giving an idea of the extent to which the company proposes to operate.

Besides Mr. Sadek, who is widely and favorably known in the metal trades, the officers of the new company are: I. Gerson of Toledo, president; L. R. Grosslight of Detroit, treasurer, and S. Gerson of Toledo, secretary.

—

Detroit Battery to Double Plant and Production

DETROIT, MICH., Aug. 9—Indianapolis men and capital are now principally interested in the Detroit Battery Co., which recently increased its capital stock from $10,000 to $60,000. The business of this concern has been growing steadily and now it is planned to double the size of the plant as well as its production. S. W. Elston, who was secretary-treasurer of the Pumpelly Battery Co., Indianapolis, is president and general manager of the company; W. A. Petzold, secretary-treasurer of the J. L. Hudson Co., Detroit, is vice-president; Sol Meyer, banker, Indianapolis, is treasurer, and M. G. Pierson, formerly of the Kelsey Wheel Co., Detroit, is secretary. W. H. Ducharme, treasurer of the Kelsey Wheel Co., is also interested in the concern.

—

Rowe Co. Expanding

EAST DOWNINGTOWN, PA., Aug. 7—Samuel J. Rowe, president of the Rowe Motor Mfg. Co. of this city, stated today that his company expected to break ground soon for an addition to its plant. This addition will be necessary to increase the capacity of the plant as the concern has recently received a contract for some foreign business. The extension will be 200 ft. long and 70 ft. wide built of brick.

—

Ford-Clark to Furnish Parts

CLEVELAND, OHIO, Aug. 9—The Ford-Clark Co. has equipped a plant at 6536 Carnegie Avenue for supplying jobbers, dealers, garage and repair men with parts formerly difficult to obtain in small quantities for repair and replacement purposes.

The line will consist in part of robe rails, springbolts, foot rails, windshields, inlet and exhaust valves, hood fasteners, spring oilers, drag links and bumpers.

The equipment of the machine shop is especially designed to take care of repair orders for motor valves and gr cup spring bolts, and is in charge man who has had extended experi with these parts.

A full line of blanks will be car and it is the intention to finish the any size on short notice.

The officers of the company are: Ford, formerly with the Steel Proc Co., Cleveland, president; A. C. C formerly with the Detroit Seamless Tubes Co., Detroit, vice-president; I Bracken, secretary and treasurer.

—

Firestone Employees on Annual O

AKRON, OHIO, Aug. 9—Employe the Firestone Tire & Rubber Co the number of 15,000, enjoyed annual outing at Silver Lake Par Saturday.

Two of the big thrills of the day produced by Barney Oldfield raci his 100 hp. Fiat Cyclone, and De Thompson, the aerialist, who exh his hair-raising feats of "loopin loop" and flying upside down. A ball game in the morning betwee factory and general office depart resulted in a scrappy contest fo coveted prize of $50 to the wi team.

At noon everybody sat down t ner, corralled by the time-honore tom of the "family basket" idea. afternoon was replete with sports kinds. There were foot races, r races and water sports.

—

Cunningham Employees on Out

ROCHESTER, N. Y., Aug. 7—Th ployees of the James Cunningham Co., this city, took a holiday to-da 400 of them picknicked at Islan tage.

—

Sterling Not to Move

DETROIT, MICH., Aug. 9—The that the Sterling Motor Co. wi into another plant is denied by of that company. The company 225 men.

—

Buick's July Payroll $530,9

FLINT, BICH., Aug. 7—The Motor Co. paid $530,934 wage employees in July, thus setting record in its history. Of th $293,123 was the pay-roll for th half of the month.

—

J. M. Co. to Represent Nationa

NEW YORK CITY, Aug. 7—T Shock Absorber Co. has secure clusive sales agency for Nati and tubes in Philadelphia and N The J. M. company proposes to repairs on National tires free without this added service aff list price of the tire or the guarantee.

Factory Miscellany

Sewell Wheel Expands—The Sewell Cushion Wheel Co. is enlarging its plant and it is possible that within the next 12 months an entirely new plant will be started. The company is located at Detroit.

Benford's New Plant—The Benford Mfg. Co., Mount Vernon, N. Y., manufacturer of spark plugs, will build a two-story plant on Pearl Street, west of Fourteenth Avenue, at an estimated cost of $15,000.

Borgess Rubber Plant Starts—The Borgess Automobile Co. plant has resumed operation following a directors' meeting held recently at which Grant Ashcroft of Jersey City was secured as superintendent of the plant.

Giant Tire Business Grows—The plant of the Giant Tire Co., Akron, Ohio, is working at full capacity 24 hr. a day in spite of the recent improvements in equipment. Shipments to its branch stores throughout the country are being forwarded as rapidly as its facilities will permit.

Hesse Co. Adds—The Hesse Carriage Co., Kansas City, Mo., in the past few months becoming large manufacturers of automobile bodies, is erecting a two-story building on 50 by 133 adjoining their present quarters, the steel being designed to carry five stories. The addition will cost $25,000.

Millbury Mills Busy—A 190,000-yd. order of mohair automobile cover material has made it necessary for the Millbury Mills, West Millbury, Mass., to start night work. The factory cloth will be shipped to New York City, where it will be put through a waterproofing process. The mill has fifty-eight looms.

Dreadnaught Tire Looking for Site—The Dreadnaught Inner Tube Armor Co., Toledo, Ohio, recently incorporated with a capital of $25,000, has been organized and is looking for a factory site for the manufacture of inner tubes and tires. They claim to have a puncture-proof inner tube, which is protected by patents.

Apperson Makes Addition—Apperson Brothers Automobile Co., Kokomo, Ind., has started an addition to one of its plants. This will give the company an additional 150,000 sq. ft. of floor space, which will be utilized for general manufacturing. The Apperson company completed in July the greatest business for a single month it has ever enjoyed.

Colorado Tire Makes Addition—The Colorado Tire & Leather Co., Denver, Col., is building a two-story addition to its plant that will double the present capacity, making a total of 95,608 sq. ft. of floor space. The 250 employees were given an outing recently at the expense of the company. $100 is offered as a prize for a name for the new tire protectors made by the concern.

Vulcanized Products Expands—The Vulcanized Products Co., which started in business in Muskegon, Mich., several years ago, confining itself to the manufacturing of automobile tire accessories, mechanical molded goods and electrical insulation, will begin manufacturing automobile tires and tubes by Sept. 15, provided its new building is completed on time. About fifty men will then be employed and it is expected that an output of 200 tires and tubes daily will be possible.

Gordon Expands—A Columbus (Ohio) real estate brokerage firm has started the erection of a large addition for the J. P. Gordon Co., located immediately north of the present building on Fourth Street. The general contract for the structure has been awarded and it is to be completed by Nov. 1. The addition will be three stories high with basement, 40 by 90 ft. It is to be occupied as a stock room and office. The J. P. Gordon Co. manufactures a varied line of automobile clothing and accessories.

Canadian Ford Expands—Work on another new addition to the Ford Motor Co.'s plant at Ford, Ont., at an estimated cost of $60,000 has been started. It will extend for 705 ft. along the Detroit River frontage. Hardly had the concrete work on the recently completed $300,000 factory become dry when it was decided to start the present work. The newest building will be one story, of concrete, with a steel saw-tooth roof. It will be devoted entirely to machine-shop work. Although over 150 Ford cars per day are being turned out by this plant—running at capacity—production has not kept pace with orders, and the new machine shop will allow a faster output. To insure solid foundations on the river bank 450 piles are being driven deep, and concrete sunk on top of these.

The Automobile Calendar

Aug. 21-22.....Elgin, Ill., Road Races.
Aug. 22.....Ventura, Cal., Show.
Aug. 24-28.....Columbus, O., Show, Ohio State Fair, Columbus Auto. Show Co.
Aug.....Peoria, Ill., Second Northwestern Road Congress.
Aug. 4.....Twin City, Minn., 500-Mile Race; Twin City Motor Speedway Co.
Aug. 9-13.....Indianapolis, Ind., Show, Indiana State Fair.
Aug. 6-13.....Detroit, Mich., Show, Michigan State Fair.
Aug. 6-7.....Hamline, Minn., 2-Day Meet at State Fair Grounds between Minneapolis and St. Paul, State Fair.
Aug. 13-21.....Milwaukee, Wis., Show, Automobile Dealers' Assn.
Aug. 13-17.....Oakland, Cal., Pan-American Road Congress.
Aug. 15-19.....Peoria, Ill., Illinois Garage Owners' Assn. Convention.
Aug. 19.....Providence, R. I., 100-Mile Race, Narragansett Park Speedway, Inc.
Aug. 19-25.....Los Angeles, Cal., Show, Shrine Auditorium.
Sept. 20-25.....San Francisco, Cal., International Engineering Congress.
Sept. 24.....Indianapolis, Ind., S. A. E. First Section Meeting.
Sept. 27-Oct. 10...Denver, Col., Show, International Soil Products Exposition, Automobile Trades Assn. of Colorado.
Oct.....Dallas, Tex., Show, Dallas Automobile Dealers' Assn.
Oct.....Los Angeles, Cal., Broadway Automobile and Flower Show, Automobile Dealers' Assn.
Oct. 1-2.....Trenton, N. J., Track Races; Inter-State Fair.
Oct. 2.....New York City, Sheepshead Bay Motor Speedway Track Meet.
Oct. 2.....Fresno, Cal., 150-Mile Race, District Fair, Fresno County Agricultural Assn., C. G. Eberhard.
Oct. 2-9.....Cincinnati, Ohio, Show, Music Hall, Cincinnati Automobile Dealers' Assn.
Oct. 3-10.....St. Louis, Mo., Show, Forest Park Highlands, St. Louis Automobile Manufacturers and Dealers' Assn.
Oct. 4, 5, 6.....Columbus, O., Garage Owners Convention.
Oct. 6-16.....New York City, Ninth Electrical Exposition and Motor Show at Grand Central Palace.
Oct. 9.....Indianapolis, Ind, 100-Mile Invitation Race, Motor Speedway.
Oct. 11-12.....Dayton, O., National Paving Brick Manufacturers' Assn., Annual Meeting.
Oct. 14.....Chicago, S. A. E. Standards Committee Meeting.
Oct. 16.....Chicago, Ill., 350-Mile Race, Chicago Speedway.
Oct. 18-19.....Cleveland, O., Hotel Statler, Sixth Annual Convention, Electric Vehicle Assn. of America.
Nov. 1-3.....Pasadena, Cal., Show, Hotel Green, Walter Hempel.
Nov. 18.....Arizona 150-mile Grand Prix.
Nov. 29-Dec. 4....Electric Prosperity Week.
Dec. 31.....New York City, Show; Grand Central Palace.
Jan. 22, 1916.....Chicago, Ill., Show; Coliseum.
March 4-11.....Boston, Mass., Truck Show, Mechanics Bldg.

The Week in the Industry

Warnsholdt Wichita Ford Manager—H. G. Warnsholdt has been appointed branch manager of the Ford plant in Wichita, Kan.

Hobson King's Pacific Coast Representative.—C. W. Hobson has been appointed Pacific Coast representative for the King Motor Car Co.

Fisher in Terre Haute—Walter Fisher, formerly of the Cadillac agency in Chicago, has become agent for the same car at Terre Haute, Ind.

Tullis Representing English Co.—N. L. Tullis of Vancouver, B. C., has been appointed to look after the interests of the Leyland Motors, Ltd., of Leyland, England.

Dowse Resigns—E. P. Dowse, who has been manager of the Toledo branch of the Goodyear company, has resigned his position to accept a position with another tire company.

Miller Heads Detroit Victor Rubber—Offices have been opened in the Whitney Building, Detroit, by the Victor Rubber Co., Springfield, Ohio. E. H. Miller is local manager.

Hart White's Edmonton Mgr.—M. L. Hart, until recently manager of the White Motor Car Co.'s branch in Edmonton, Alta., has been placed in charge of the Montreal branch.

Glenn Heads Louisville Tire Co.—The Glenn Tire Co. has opened an office at 331 East Broadway, Louisville, Ky. J. P. Glenn is the manager. The concern handles Goodyear truck tires.

Hirsch Chalmers California Representative.—The post of factory representative for the Chalmers Motor Co. in California has been given to J. Hirsch, with headquarters in San Francisco.

Spencer Is Promoted—E. W. Spencer, manager of the sales promotion department of the Studebaker Corp. factory, has been promoted to assistant manager of the Kansas City, Mo., branch.

Cuthbert Chalmers Wholesale Manager—Russ Cuthbert will hereafter have charge of the wholesale end of the L. H. Rose-Chalmers Co. in California, and distribute the Chalmers throughout the State.

Bruske in Maxwell Publicity Department—Paul Hale Bruske, who was manager of the racing team of the Maxwell Motor Co., Detroit, Mich., until this company decided to withdraw from racing, is now a member of the publicity department.

Motor Men in New Roles

Bement Succeeds Pardington—A. F. Bement, who was director of publicity of the Lincoln Highway Association, has been chosen to succeed the late A. R. Pardington, who was vice-president and secretary.

Reed with Donovan—M. N. Reed, formerly associated with Frank B. Donovan in Boston, has taken charge of the sales for Frank B. Donovan (Incorporated), the new Studebaker distributor in Baltimore, Md.

Stubbs Joins Northwest Motors—P. D. Stubbs, formerly western manager for the Hudson Motor Car Co., has become permanently connected with the Northwest Motors Co., Seattle, Hudson and Packard distributor.

Spalding Milburn Electric District Manager—Will Spalding, the Milburn & Walker electric representative with headquarters in Portland, Ore., has been appointed district manager for the Milburn interests for Oregon, Washington, Idaho and British Columbia.

Price Coming East—Frank Price of the Swan Carbureter Co. is on his way from San Francisco to Detroit. He will follow the route of the Lincoln Highway, placing agencies and service stations along the way. The company has a service station in Santa Barbara, Cal.

Branstetter Heads Kissel Retail—H. P. Branstetter, Wabash Avenue and Twenty-sixth Street, Chicago, who has handled the wholesale business for the Kissel Motor Car Co., covering Illinois and Indiana territory, has been given charge of the retail Kissel business in Chicago in addition.

Reeser Willard Assistant Manager—E. B. Reeser has been appointed assistant district manager of the Detroit, Mich., offices of the Willard Storage Battery Co. Mr. Reeser was at one time manager of the Chicago branch of the Kellog Mfg. Co., and more recently was traveling for the Willard company.

Earl C. Anthony Makes Changes—Earl C. Anthony, Inc., announces the following changes in Reo distributing force in California: F. A. Norberg has been placed in charge of the Reo truck department in San Francisco. W. M. Broodie will hereafter act as traveling representative for the Reo in California. L. F. Reed has been appointed resident manager of the company in Fresno, Cal.

Foster Makes Change—Newton Foster, formerly of Boston, has purch
an interest in the NePage, McK
Automobile Co., with headquarters i
attle, and hereafter this company w
known as the Newton Foster Co.,
will act as distributor in Western V
ington for the Paige and National
The salesrooms and mechanical
are located at 1512-1522 Eighth Av

Pennell Heads Fort Wayne F
The new Ford agency has been e
lished in Fort Wayne, Ind. The b
is now in charge of J. C. Pennel
five years connected with the D
branch. J. C. Smith, in charge o
Indianapolis branch, is assisting in
lishing the new agency. Brosi
Brosius, who for several years ha
Ford branch in Fort Wayne, will
tinue in the automobile business at
place on East Main Street.

La Casse Maxwell Branch Mana
W. J. La Casse, prominent figure
automobile industry in Portland,

The AUTOMOBILE

Brass and Bronze—Offsprings of Copper

Copper the Trunk of the Non-Ferrous Family Tree, with Zinc Forming the Brass Branch and with Tin, the Bronze

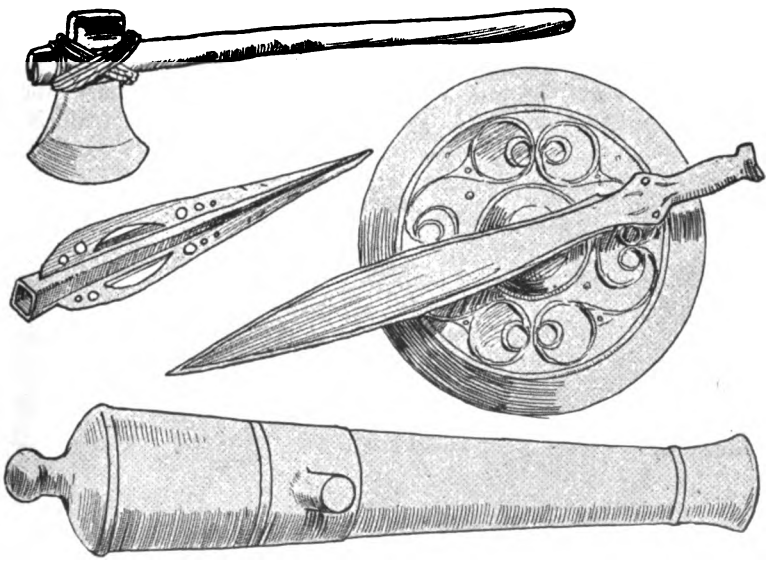
Part 1

By J. Edward Schipper

IN the bowels of the earth below mighty Mount Aetna was the workshop of the one-eyed giants called the Cyclops. Here, according to the mythology of the ancient Greeks, Polyphemos, chief of the giant band fashioned the thunderbolts for Jupiter and also in his roaring furnaces produced huge implements of bronze. With a thunderbolt forged from this metal Jupiter killed Aesculapius, the son of Apollo. Such is the mythical beginning of the great industry of the manufacture of bronze.

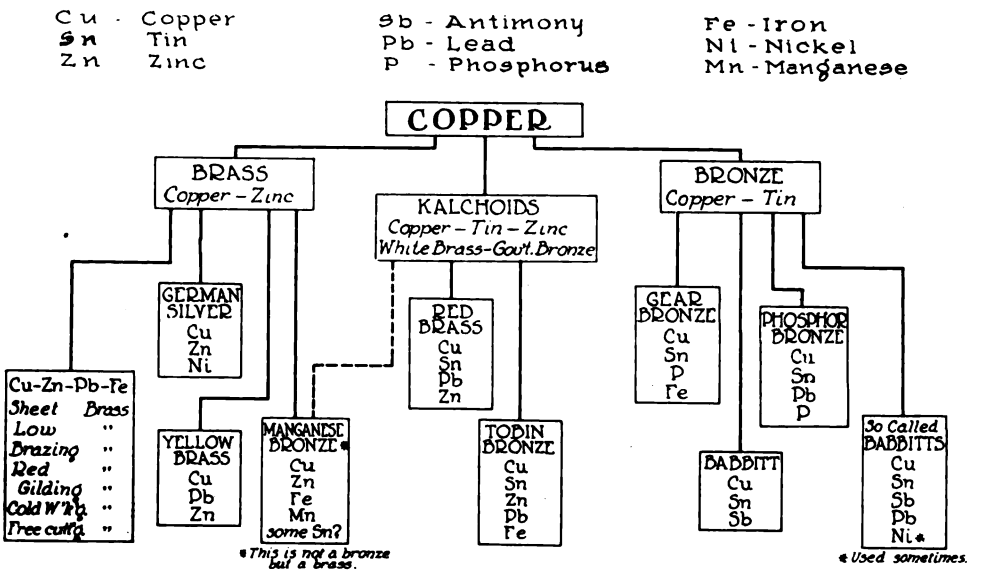
Leaving the realm of the gods and coming down to the kingdom of man, archaeologists assert that between the periods of human culture known as the stone age and the iron age, there was a period called the bronze age. These three great periods of human development overlapped, they say, as is proved by the fact that implements have been found composed of stone and bronze, of bronze and iron and even in a few cases of stone and iron, showing that the bronze age bridged quite incompletely the lapse in time between the periods of stone and iron. The bronze age is thought to have existed 2000 B. C. in several scattered parts of the world.

A Greek manuscript of the eleventh century, one of the prized possessions of the library of St. Marks, Venice, gives the composition of bronze as 1 lb. of copper combined with 2 oz. of tin. From that time on records are plentiful mentioning bronze and its uses. The bronze of classical antiquity consists of copper alloyed with one or more of the metals zinc, tin, lead and even silver depending on the time and the use for which the alloy was intended. From the analyses of old coins it is learned that the Greeks used an alloy of copper and tin until about 400 B. C. when they began to substitute lead for tin with increasing frequency. In the oldest bronze relics the copper content varies between 67 and 96 per cent.



Bronze weapons from the bronze age to the nineteenth century

The ancient history of metals which have copper as their base is not confined to the old world. The American Indians had ornaments which were made from copper and from natural alloys of that metal. The mound builders whose relics are found over vast areas of North America were familiar with copper in many



The non-ferrous family tree, showing a few of the metals in common use and how they are connected to the mother-metal copper

localities although the races which are so classified are said to have belonged to the stone age. Copper and tin were mixed and tempered by the Aztecs and made into useful ornaments and tools. The same metal which has been excavated from the site of ancient Troy has been found in the haunts of old American civilization. Arrowheads, chisels, knives, beads and numerous other articles are found buried beneath the sites of old Indian villages and in the tribal graveyards as well as in the localities where 4000 years ago the Chaldeans practised the infant art of metallurgy.

Brass a Later Development

Brass, the twin sister of bronze, is a later development. The metal brass is mentioned in the Bible but it is debatable if the metal were not bronze. The distinction between the two is rendered difficult because although bronze is a mixture of copper and tin; and brass a mixture of copper and zinc, it was not until the time of Queen Elizabeth (1533-1603 A. D.) that a clear distinction between zinc and tin was realized. At that time however, Queen Elizabeth granted to William Humphrey a patent allowing him the exclusive privilege of making brass by a certain definite process. This establishes the earliest positive date of non-ferrous commercial venture.

Since the Elizabethan era a definite distinction has existed between the two metals, bronze and brass. These two metals, which according to students of antiquity were the bronze of the old Phoenicians and Greeks, are now the framework which supports the structure of our modern house of non-ferrous alloys. The formulae which were used for the ancient coinage are still employed for entirely different purposes although the actual processes of manufacture have undergone such changes that even Polyphemos with his superhuman knowledge of metallurgy would pause in wonderment.

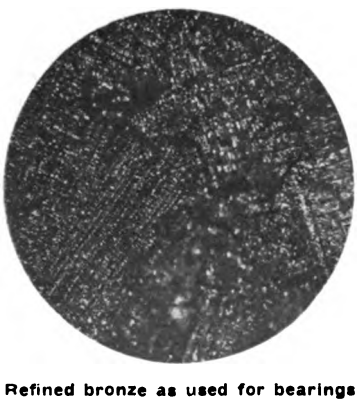
The Non-Ferrous Family

The bronzes and brasses are a family.

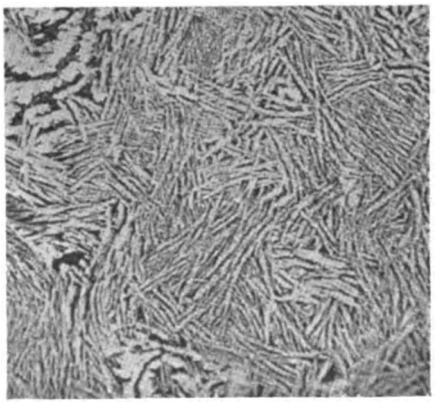
They spring from a common ancestor, which is copper. Like a family divided into two broad divisions by the descendants of brother and sister, so the brass and bronze family is divided into two broad divisions. The trunk of the family tree is copper but on one side grows the tin branch and on the other the zinc. On the tin side are the bronzes, on the zinc sides the brasses. Copper and tin make bronze. Copper and zinc make brass.

If two branches of a great family are to be distinguished from each other they must have certain characteristics of temperament, appearance, character or some other mark of distinction. The non-ferrous family with its two broad divisions of brass and bronze does exhibit such main distinctive features but there are so many other metals which have entered into the combinations of non-ferrous alloys that these main distinctions are often so subdued, or even nullified, that to the casual observer it would be bewildering to trace the primary differences. Brass, however, must of necessity partake of the nature of zinc and must show its effects, hence it is softer than bronze which contains tin, a hardener of other metals. The qualities of ductility and malleability would hence follow through the brass branch of the family were not the qualities of other alloying substances to interfere; and hardness and tenacity would be the main qualifications of bronze were it left unaffected by the introduction of other elements.

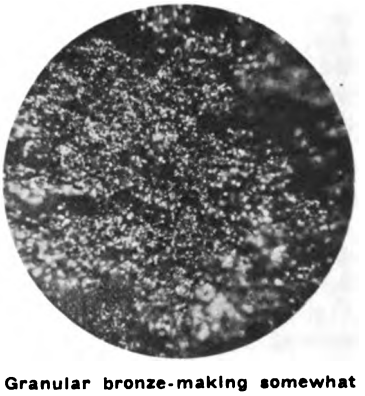
One branch of a family might in itself have the qualities of even temperament and quiet mentality, where another may have fiery tempers and be filled with restless energy, but the introduction of new members into that family may alter the entire characteristics. So it is with the great non-ferrous family, which though it springs from the common mother-metal copper, yet possesses such a world of characters that it can be adapted to widely varying uses. On one side there may be a giant forging, and on the other hand a soft bearing liner. Certainly there could not be two sets of requirements so widely different and yet these



Refined bronze as used for bearings in automobiles



Chilled bronze casting quenched in mould



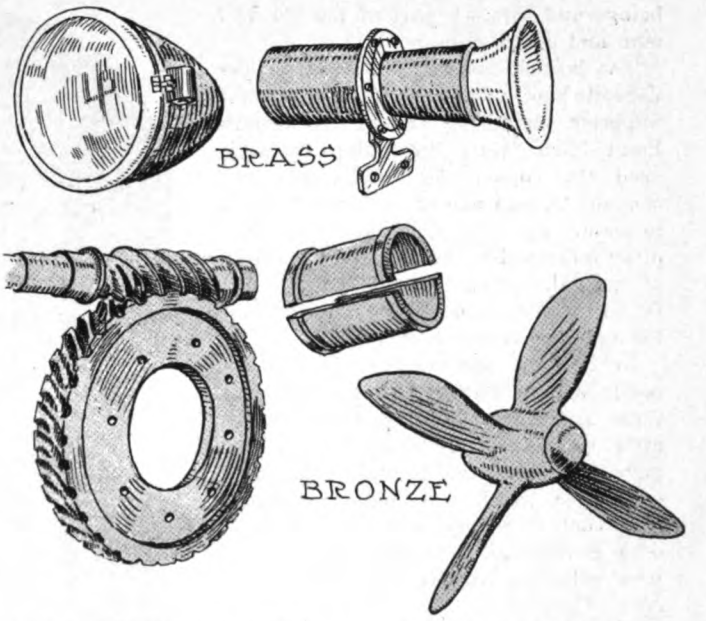
Granular bronze-making somewhat inferior wristpin bearing metal

metals are both offsprings of the same parent metal. It is far from true to suppose that the whole mass of non-ferrous alloys springing from the common base copper can be classified under the heads brass and bronze. Clear as the original compositions of these two metals are, the brasses and bronzes of to-day can not be dismissed by this simple classification because many of the alloys contain both zinc and tin. This would make them both, brass and bronze, or neither. Manganese bronze in common use, is an example of this. This often contains both tin and zinc and as a result falls under both heads and to-day committees appointed by the engineering societies are wrestling with the problem of a definite classification of them. It has been suggested that the entire brass and bronze classification be cast aside and the metals divided into forging and non-forging.

Qualities of Copper Imparted

Copper, as the mother-metal, must impart some of its qualities to its offspring regardless of the number and quality of the alloying substances added. In studying the characteristics of a certain family, we would look for them first in the root of that family. Therefore to know something about the family of non-ferrous metals, we must first study copper. If the ancestor of a family is unyielding and war-like in character, we would scarcely look for the descendants to be agriculturists. If copper were hard, brittle and heavy, or on the other hand soft and light, it is of interest to know how these qualities have been utilized in the products developed from it, what alloying substances have been added to subdue one quality and to accentuate another and so on throughout the gamut of reasons for alloying metals.

Ductility, malleability and tenacity are the three great qualities of copper. It is the possession of all three that endows it with its peculiar importance in machine and structural work. In addition it has a high melting temperature, fusing at about 1930 deg. Fahr. as compared with lead at 625 deg. Fahr. It is high in electrical conductivity and in heat conductivity is second only to silver, the highest, having a capacity in this respect of 73.6 per cent of that of silver.



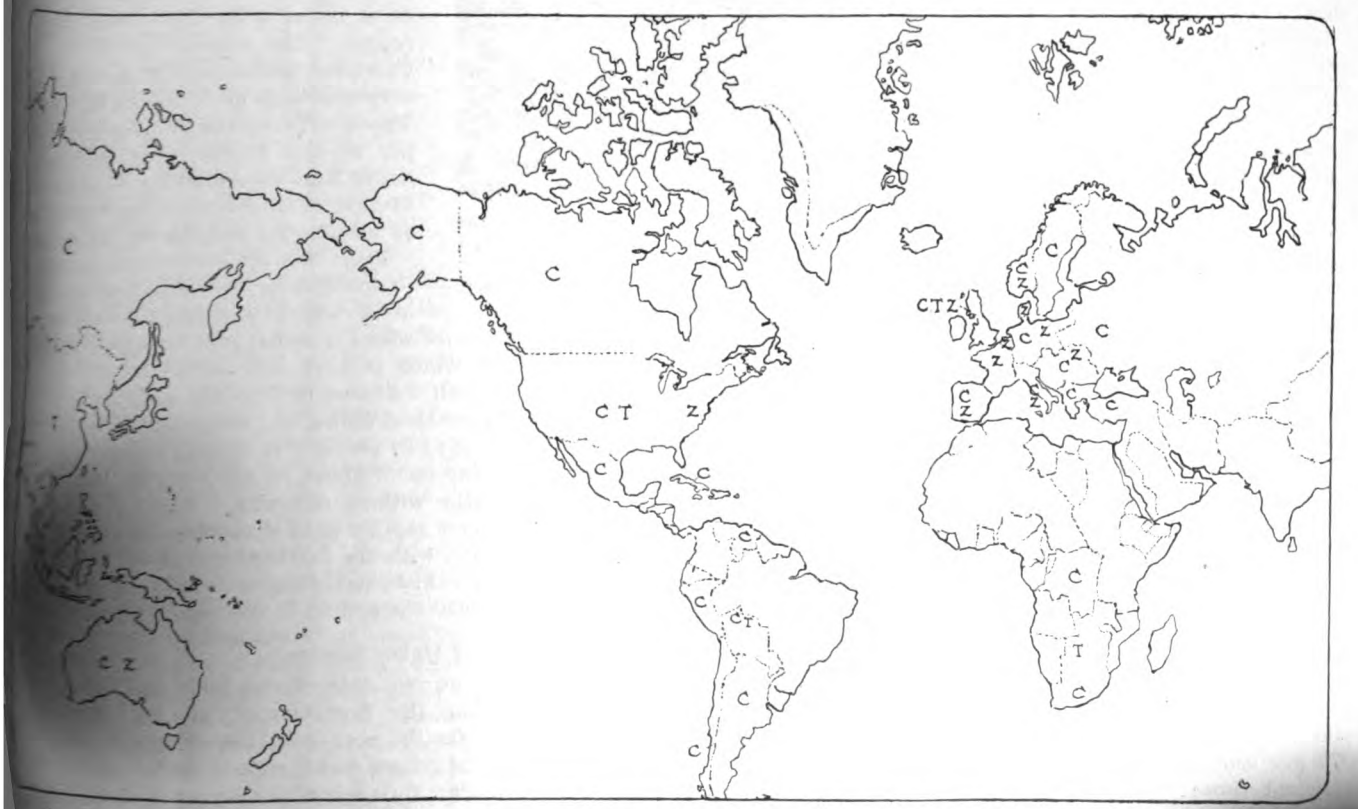
Brass and bronze articles of highly important commercial use

The tensile strength of copper is 20,000 to 30,000 lb. per square inch or about a third of crankshaft steel and in weight it is about nine times as heavy as water having a specific gravity of 8.95.

Heredity of Non-Ferrous Family

These are the family characteristics of the mother-metal copper. These are the family traits which can be traced though, at times very faintly, throughout the great family of non-ferrous metals springing from this common ancestor.

In nature copper is most widely distributed. It exists in sea weed and the blood of certain mollusks. It is part of the composition of straw, hay, eggs, cheese, meat and other articles of food. It is in the liver and kidneys of human



Map showing the parts of the world which produce most copper, tin and zinc, which are indicated by the initials C, T and Z

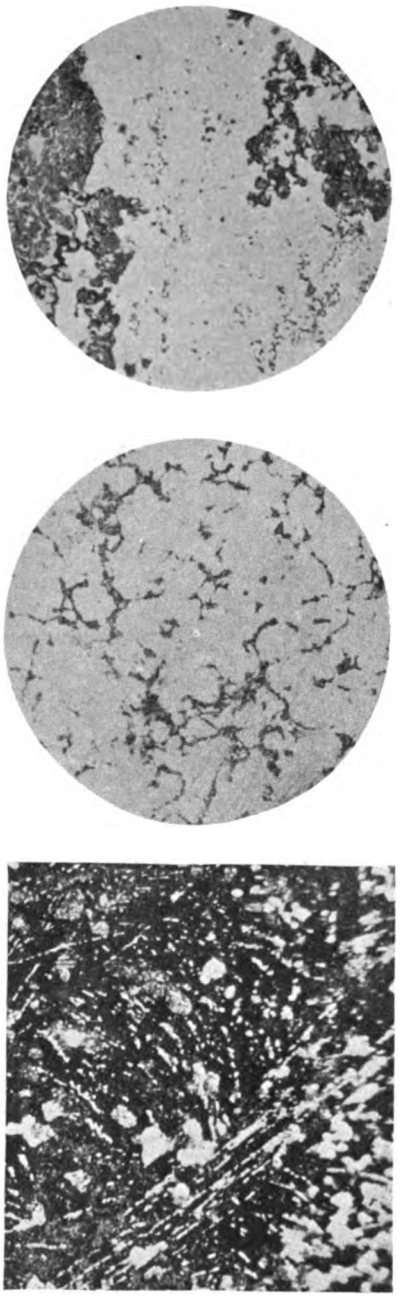
beings and forms a part of the blood of man and other animals.

The largest masses of natural copper deposits known are those found near Lake Superior centering about Keweenaw Point, Mich. Here, the Indians formerly used the copper for implements and ornaments, and one of the metals found in connection with it is silver, which is often imbedded in the copper in the form of crystal. Other copper deposits are found in Tennessee, New Jersey, and through the Mississippi Valley.

In foreign countries the largest deposits are in South Australia, Siberia, Chile and Peru. The ores are moderately rich, generally above 50 per cent pure. Some of the sulphur compounds of copper which are found as copper ores, contain 80 per cent, whereas other ores containing a large proportion of iron sulphide, contain less than 5 per cent of copper.

Three principal methods are used for reducing copper from its ores: They are known as the pyro-metallurgical or dry method; the hydro-metallurgical or wet method; and the electro-metallurgical or electrical method.

The process used depends upon the ore, and the locality in which the refining is done. The impurities contained in coarse copper are mainly iron, lead, zinc, cobalt, nickel, bismuth, arsenic, antimony, sulphur, selenium and tellurium. These are generally eliminated by oxidizing, transforming the products into slag, or gases or by electrolysis. When the Bessemer method of decarburizing pig iron was discovered, it was immediately utilized for copper but it was found that in the converters used for iron, the tuyeres were not arranged to suit the action of the copper. The converters were improved and in 1911, more than 400,000,000 lb. of copper were made. By the electrolytic method the gold and silver content of copper ores are saved, whereas they were formerly lost.



While heat has its influence on the micro structure, its influence is not utilized as in steel. The above photomicrographs show some of its effects

Tin Has Ancient History

Tin which is combined with copper to form bronze is of an entirely different nature. Being one of the metals which enter into the composition of bronze, it was known thousands of years before the existence of authentic history. This is the other of the two metals which started the bronze division of the non-ferrous family. The ancients did not know the difference between tin, lead, zinc and other metals of somewhat similar characteristics, and it was in the fourth century that tin began to assume the characteristics of a definite product. The early Greeks named the metal Hermes after the god who corresponds with the Roman Mercury, the messenger of the gods. This was one of the metals used and fabricated in the firey furnaces of the Cyclops and from the accounts of mythologists, traces its ancestry back to the time of the Greeks and Phoenicians.

Tin is mined in England, Saxony, Bohemia and the Straits Settlements. The ores after preliminary washing carry 65 to 75 per cent of metallic tin. Thus, this metal which in the ancient times was found in close proximity to the copper deposits, as is shown by the fact that the two were combined in fashioning the crude implements of pre-historic times, is now drawn from an entirely different quarter of the earth.

Two processes are used in smelting the ores, both being by furnace: The first, crude implements of pre-historic times, tical circular, or sometimes rectangular hollow shaft in which are placed alternate layers of coke and ore. An air blast introduced near the bottom of the furnace carries the flames throughout the shaft.

The second, is a reverberatory furnace in which the process consists of mixing the purified ore with about one-fifth of its weight of anthracite coal, which is moistened and then fused on the sole of the furnace for 5 or 6 hr. The slag and metal produced are then run off, the latter being cast into bars which are refined and freed from impurities, chiefly iron, arsenic and copper. It is one of the traditions that in refining tin, an inclined hearth is used in which the pure tin runs off and is further purified by stirring with the branch of an apple tree. In testing for purity, the workman heats the tin bar until quite near the melting point and then drops it to the stone floor. If the tin is pure it will splash into a series of granular strings.

Tin a Great Hardener

The physical qualities of tin give little clue to what its action would be when combined with other metals. Studying its qualities alone, it would not be thought that this necessary element in bronze would have such a marked effect on a metal with the characteristics of copper. The specific gravity of tin is 7.293, the metal is white, lustrous, soft, very malleable and has but little tenacity. The tensile strength is about 3500 lb. per sq. in. It fuses at 442 deg. Fahr. has a heat conductivity of 14.5 per cent of that of silver and finds its chief use as an alloying substance.

From the specifications of the metal, it would never be suspected that it is one of the best known hardeners in existence. This is an instance where a metal soft in itself, unites with another metal which is also soft with the result that it hardens it to such a degree that it can only be turned in a lathe with the greatest difficulty. When tin is added to copper to the extent of 30 per cent it attains its maximum hardness. Containing up to about 24 per cent tin bronze can be turned in a lathe without difficulty. After that point, the hardness increases rapidly until it reaches its maximum from 30 to 40 per cent, with the further increase of tin, the hardness decreases. The maximum strength of the alloy is reached with 17.30 tin and 82.70 copper.

Zinc with Copper Makes Bronze

While tin is on one side of the scale and together with copper makes up the fundamental mixture of the bronze division of the family, zinc is on the other side and in combination with the parent metal copper, makes up the body of the brass division. Zinc resembles copper in that it is ductile

and malleable, although to a much less extent. Its tenacity, however, is far less than that of copper, being about 1/10 that of iron, as is shown by its tensile strength of 6000 lb. per sq. in. One of the remarkable features of zinc is its non-corrosive quality due to the fact that upon the surface there forms a thin film of carbonate of zinc which protects the metal from corrosion.

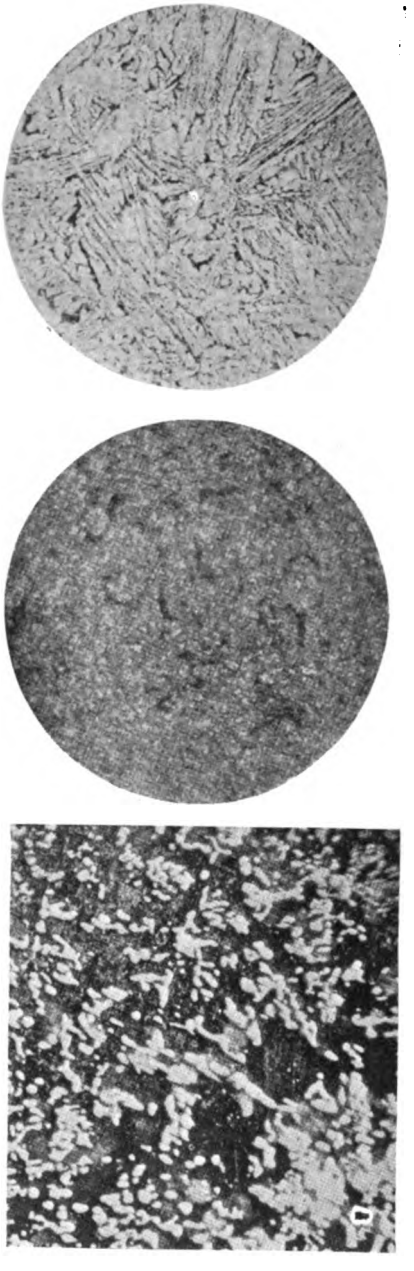
In the tales of antiquity zinc plays as important a part as the other metals which have been spoken of. Aristotle refers to brass as the metal of the Mosynoeci. It is also referred to frequently in the writings of Pliny, who mentions a metal cadmia which served for the conversion of copper into another metal which he called aurichalcum. As late as 1702 the metallurgists stated that the formation of brass was the union of a metal with an earth. Subsequently these authorities adopted the view that cadmia, which was referred to by Pliny, was a metallic calx having the property of dying copper yellow.

The word zinc was first used in the form zinken, and it was not regarded as a pure metal.

Zinc and bismuth were also often confused, and both were called indiscriminately spelter, a name which still exists, although in its modern usage it refers only to zinc and is used merely commercially.

The working of zinc was part of the old Indian civilization, being described in 1597 by travelers as a peculiar kind of tin. History is not quite clear on the date when zinc was first isolated, although it is known that the art of zinc smelting was in existence in Great Britain about 1725.

The world's supply of zinc has increased remarkably during the last century. Germany was practically the only producer of this metal up to 1833. Immediately after, Russia became one of the important producing countries, and in 1837 Belgium joined the ranks followed by England and the United States, which commenced to produce at the rate of 6000 tons per year in 1873. At the present time, the biggest producers are the United States, Germany, England, France, Spain, Austria and Belgium. The world's supply of zinc in 1910 was 450,000 tons. According to a report from Washington, the State of New Jersey is an important factor in the world's supply, the zinc mines of that State having increased their output from 144,312,560 lb. of recoverable zinc in 1913 to 148,506,500 lb. in 1914.



Microphotographs showing the varied nature which can be possessed by practically similar compositions of bronze

Zinc Is Ductile

Zinc being ductile and malleable and of low tensile strength, it would be at once imagined that the alloys of copper and zinc would have great ductility and malleability although the tenacity might perhaps be low. Yet the effects of zinc are of such a varying nature, that different alloys instead of following a definite scale of increase and decrease in strength and other physical qualities, vary quite quickly with different percentages of zinc. As zinc is added, the tensile strength gradually increases from about 27000 lb. per sq. in. for 98 per cent copper and 2 per cent zinc up to 50,000 lb. for 60 per cent copper and 40 per cent zinc. The strength again decreases quite rapidly after passing 48 per cent copper to 52 per cent zinc where the tensile strength is about 24,000 lb. until it becomes as low as 1800 lb. per sq. in. with a composition of 33 per cent copper to 66 per cent zinc. Strange to say the strength again rises, becoming 18,000 lb. per sq. in. for a composition of 5 per cent copper to 95 per cent zinc.

Thus, zinc plays the rôle of a strengthener until it forms about two-fifths of the alloy; from then on down to the point where it forms two-thirds of the alloy it acts as a weakener as far as tensile strength is concerned, the strength curve again taking an upward trend until with zinc 94 per cent of the entire mixture, the tensile strength becomes 18,000 lb. or three times that of zinc alone. In other words, it is the effect of the parent metal copper upon the zinc which increases the tensile strength at this point.

One of the strange features of the brass end of the non-ferrous family is that the zinc has a marked effect upon the color of the resulting alloy. The red copper becomes a reddish yellow between 2 per cent zinc and 15 per cent, where it gradually blends into a yellow red until at 25 per cent zinc the color of the alloy becomes a pale yellow which gradually deepens as 60 per cent zinc is approached. Here the color again takes a turn, passing over into a silvery white, becoming light gray at about 61 per cent and carrying this color until it gradually becomes a dark gray at about 83 per cent zinc.

Structure Also Changes

Another strange and interesting fact about these changes of color is that the interior structure of the metal also changes, the red-yellow shade having a coarse structure at the lower percentages of zinc and then changing to a structure which becomes finer as the yellows are approached, then becoming coarse again as the darker yellows are blended into the mixture until the grays are reached when the coarse structure begins again to give way to a fine content which it holds until the mixture is pure zinc without copper.

This change of color, strength and ductility which occurs coincidentally is one of the features of the brass family which renders it distinctive. The uses to which one of these metals can be put can largely be judged by the color. The white metals which have most copper are generally too brittle for any practical use, but the yellowish metals which range between 40 and 50 per cent zinc are of great value. In fact, by proper manipulation a member of the brass family can be made for practically any purpose, and if there were no other metals in existence, the work done by most of our other metals could in many cases be quite satisfactorily accomplished by specially designed combinations of copper and zinc. Brass may be made brittle and hard and it can be made soft and weak or soft and tough. It can be smooth or rough of surface and can take a polish which is almost mirror-like.

(To be continued)

Factors in Valve-in-Head Design

Numerous Refinements and Developments—Valve Cages Eliminated—Better Combustion Chambers

By W. A. Brush*

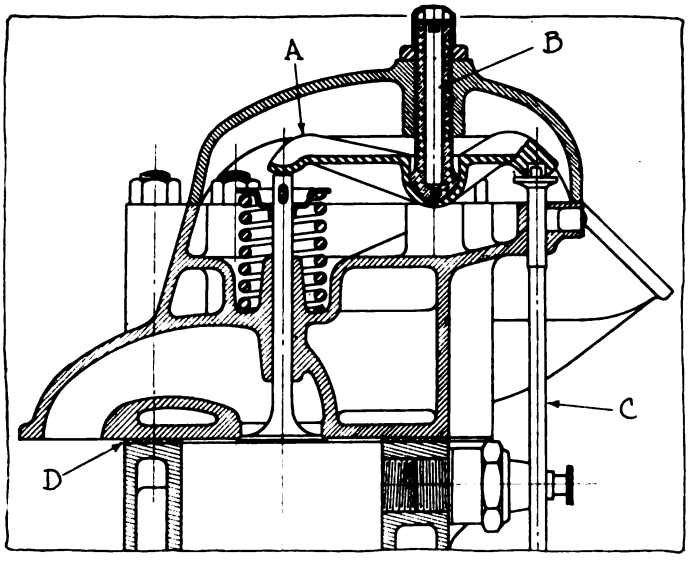


Fig. 1—Valve mechanism of Brush-developed valve-in-head motor. A—Rocker arm. B—Rocker arm stud. C—Push rod. D—Armored asbestos gasket between cylinder and head

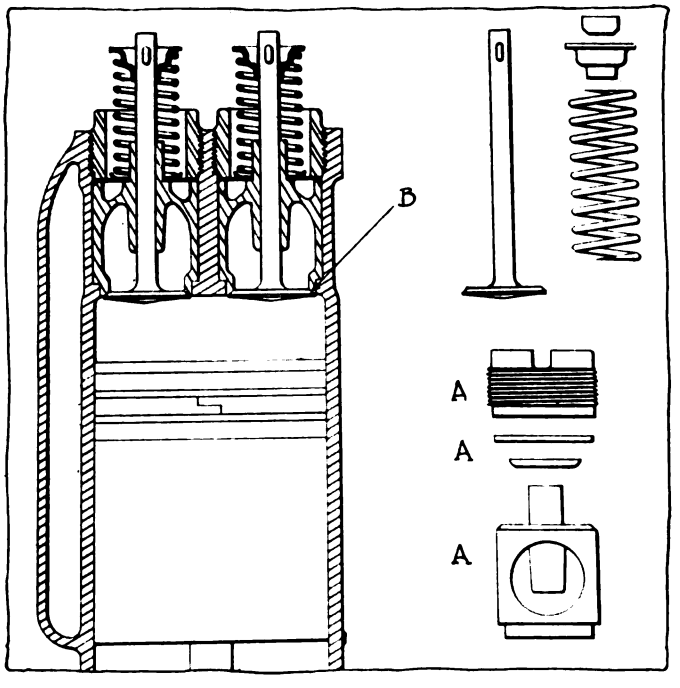

Fig. 2—Typical valve cage valve-in-head motor. A—Parts per cylinder eliminated by use of detachable head. B—Valve seat showing double wall between seat and cooling water

DETROIT, MICH.—Editor THE AUTOMOBILE:—Poppet-valve motors may be divided into two very general classes: one of these classes is the side-pocket class, that is, valves are located in valve pockets arranged at the sides of the cylinders. This class includes those motors commonly known as L- and T-head designs. The other class includes those motors which have valves located in the head of the cylinder. A great deal of skill and time have been expended by automobile motor manufacturers in refining and developing the side-pocket type of motor. Very little effort has been spent in the refinement of the valve-in-the-head motor.

The reason for this condition is not far to seek. The greater efficiency of the valve-in-the-head type has made it a popular motor, in spite of its comparatively crude design. Automobile buyers have set the seal of their approval on the overhead valve because of its efficiency, and in spite of the fact that no effort was made to improve its mechanism until within a comparatively recent period. The Brush Engineering Association, Detroit, has for the last 2 years been refining and developing this type of motor. The features which will be described are now embodied in motors made for the trade by several well known motor manufacturers.

Reference to Figs. 1 and 2 show the difference between the undeveloped and the refined type of valve-in-the-head mechanism. Fig. 2 is a typical section of the old type, valve-in-the-head mechanism, and the first thing that strikes the observer is the possibility of eliminating the valve cage and the parts necessary to hold it in place. *A* in Fig. 2 indicates the number of parts per cylinder which are not necessary in the developed type. Beyond the elimination of these useless parts, there is an added efficiency in the motor and a material decrease in the trouble possibilities, since it is evident that with valve cages, the valve and valve seat must be operated at a higher temperature than is necessary. Note that at point *B* in Fig. 2 between the valve seat and the cooling water, there are two thicknesses of metal; that is the wall of the valve cage and the wall of the cylinder proper. This means that the valve and valve seat must operate at a higher temperature than when the valve is seated directly in a detachable head as shown in Fig. 1. Operating at this higher temper-

*Editor's Note—W. A. Brush is business manager of the Brush Engineering Assn., consulting engineers, Detroit, Mich.

Right—Fig. 4—Light strong forged rocker of Brush type valve-in-head motor.

ature, both valve and seat are susceptible to undue carbon deposit and pitting. The valve itself, operating at the higher temperature, is more apt to warp and lose its shape.

Fig. 1 shows a valve seated directly in a detachable head. The water jacketing under these conditions is fully as thorough and intimate as is possible to be secured with any type of poppet-valve motor. It therefore operates at as low a temperature as possible and must therefore be correspondingly as little affected by carbon deposit. Any valve-in-the-head motor possesses the advantage over the side-pocket type of having its valves located where they are least easily reached by oil which may work up around the piston, therefore the valve-in-the-head with the valve seated directly in the head casting must, other elements being equal, require the least attention to keep it operating satisfactorily. In other words, it is the least susceptible to the valve troubles, carbonizing, pitting and warping.

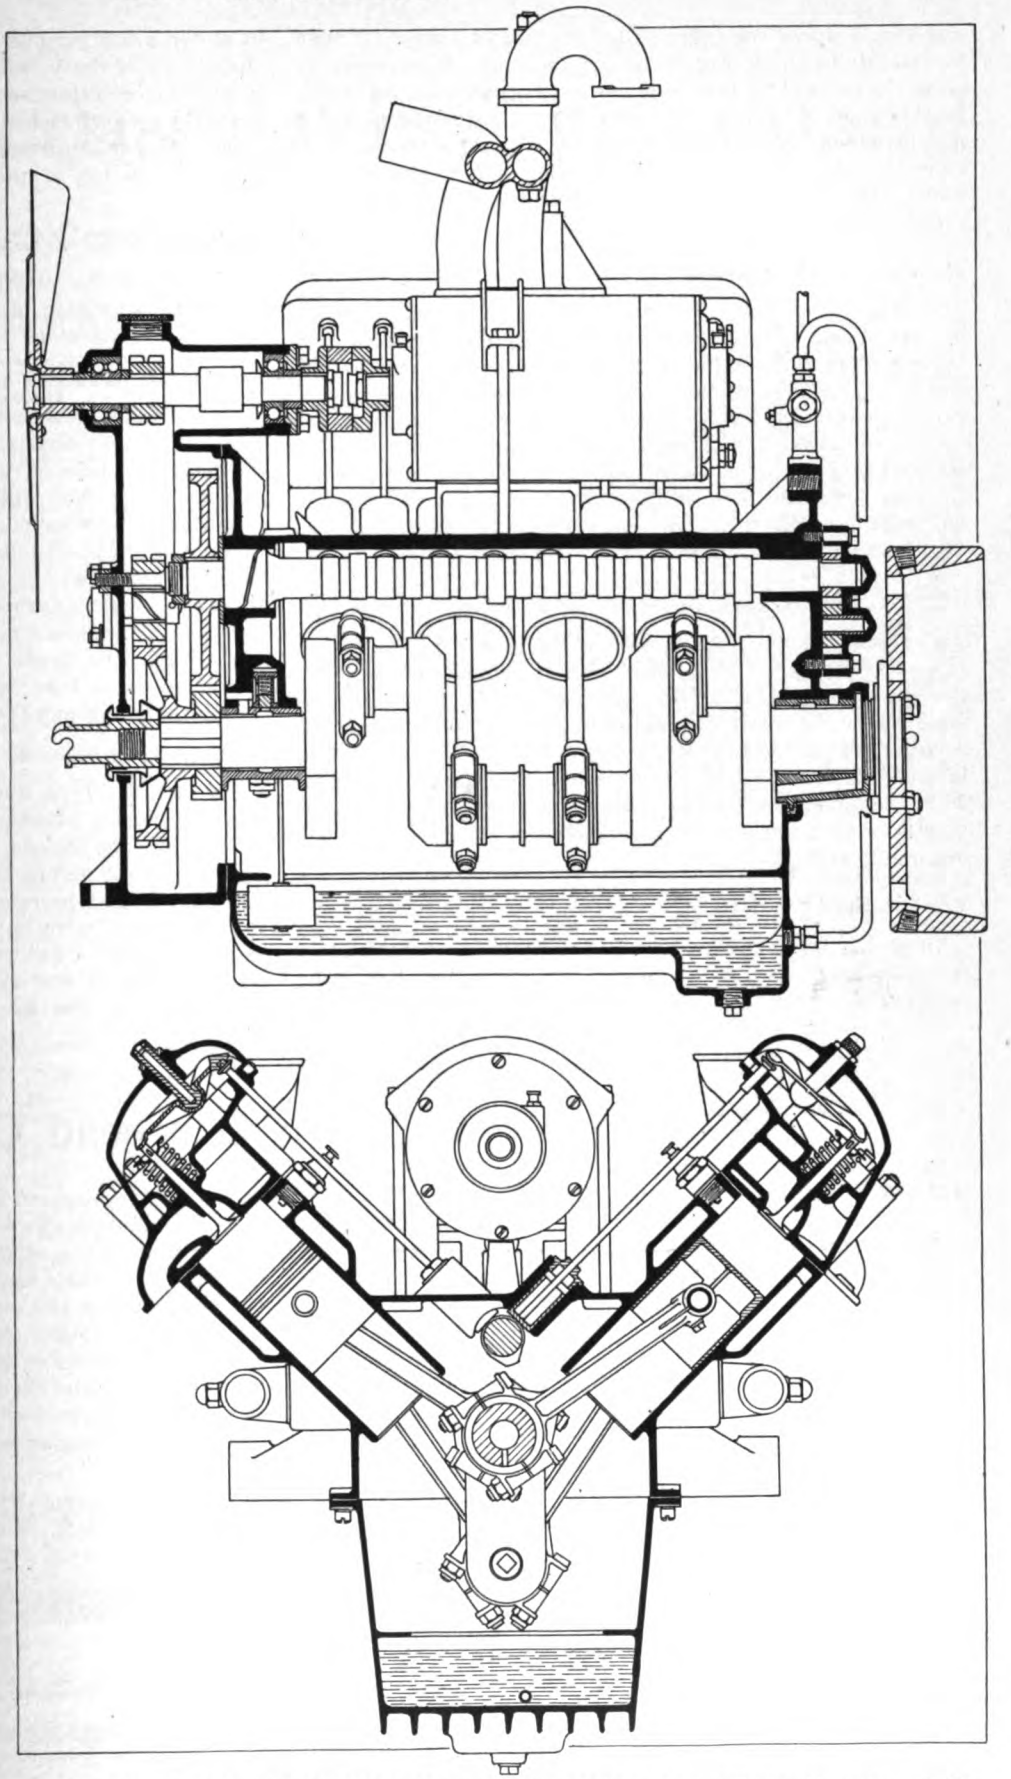
As I write this, I have on my desk a valve just taken out of a motor of this type which has gone through a 300-hr. endurance run. The motor was operated at about 1500 r.p.m. and developed at that speed about 35 b.h.p. Not only is the valve not carbonized and not pitted, but as far as may be determined by inspection, it is ready to go back into the motor for just such a run. The original marks made by grinding-in are still evident to the eye.

The detachable head secures an additional advantage: it permits a perfectly symmetrical combustion chamber with completely machined walls, and these smooth walls naturally present less opportunity for carbon deposit than do the comparatively rough walls of a casting. Practically all of the foundry problems are those which come up in connection with the comparatively small head casting.

Between the detachable head casting and the cylinder blocks there may be used the flat armored asbestos gasket, or if it is desired, the soft copper circular gasket. With properly located studs, either of these gasket arrangements may be made satisfactory.

T-Type Possibilities

Comparison of Figs. 1 and 3 shows the possibilities of refinement in overhead-valve operating mechanism. Fig. 3 is a typical section of the older journal-type of rocker



Upper—Fig. 6—Longitudinal section through two-bearing, eight-cylinder V motor of the valve-in-the-head Brush-developed type

Lower—Fig 7—Transverse section through the motor mentioned in Fig. 6. From the repairman's standpoint the fact that the valves are seated in an easily detachable head is of great advantage. For example, when the heads of the two blocks are removed, the valves may be ground in on a work bench where, by inspection, the workman may know whether or not he is doing a first class job. While the heads are off, if it is necessary to take out a piston and connecting rod for any purpose this may be done through the top of the cylinder bore

and Fig. 1 shows the refined fulcrum-type of rocker. I wish to call attention in Fig. 3 to the fact that there must be either in the end of the rocker or in the push rod, as shown in this case, provision for valve tappet adjustment, which naturally adds to the weight of the operating parts. Furthermore, when wear occurs in the journal in the center of the rocker, there is no means of compensation for this wear except by re-bushing the rocker arm.

The Fulcrum-Type Rocker

In Fig. 1, with the fulcrum-type rocker shown in detail in Figs. 4 and 5, tappet adjustment is secured by raising or lowering the hollow stud which forms the fulcrum for the rocker. This means that whenever tappet adjustment is made, there is automatic compensation for any wear that may have occurred in these operating parts. Furthermore, the well shaped seat in the rocker and the hollow stud provide capacity for a considerable amount of lubricant. The amount of oil contained in these parts is sufficient to provide lubrication for a very considerable period.

Adjusting the Tappets

Tappet adjustment on a motor of the type shown in Fig. 1 is a very simple process. The lock nut outside the cover for the valve mechanism is loosened; the stud is screwed downward while the motor is running until the push rod can just be freely revolved with the fingers. The stud is then locked in position and a satisfactory adjustment has been secured. This developed valve-in-the-head mechanism is lighter, quieter, and more easily assembled than the cruder type originally used.

Valve-in-Head Advantages

In connection with the recent popularity of the V motors it is decidedly worthy of notice that the valve-in-the-head presents some very material advantages. It is the only type of motor which permits the exhaust manifold to be placed the outside of the V, where it is entirely out of the way wh inspection or adjustment of accessories is necessary. It the only type of motor which in V construction makes p sible a tappet adjustment that is accessible, the adjustme being in the top of the head cover instead of down insi the V.

Interior of V for Accessories

This leaves the interior of the V free for intake manifo carbureter, ignition distributer, and, if desired, starti motor and generator.

From the Repairman's Viewpoint

Figs. 6 and 7 are two sections through an eight-cylind V motor of the valve-in-the-head developed type. The val in-the-head naturally retains in V construction the efficie inherent with this type of motor. Furthermore, from repairman's standpoint the fact that the valves are sea in an easily detachable head is of remarkable advanta for example, when the heads of the two blocks are remo the valves may be ground in on a workbench, where by spection the workman may know that he is doing a first c job. While the heads are removed, if it is necessary any purpose to take out a piston and connecting-rod, may be done through the top of the cylinder bore.

Simplicity and Economy

To sum it all up, this type of motor may be comple and thoroughly overhauled without removing the cyli blocks from the chassis, and there are no parts or accesso so placed that before they can be inspected other part accessories must be removed. These advantages are sec in this type of valve-in-the-head motor, not only without ing complications, but with in reality an increase in simpl and reduction in cost over other types.—W. A. BRUSH, I ness Manager, The Brush Engineering Association.

Weidely Twelve with Overhead Camshafts

INDIANAPOLIS, IND., Aug. 16—The Weidely Motor Co. of this city has brought out a twelve-cylinder motor which operates under the Weidely principle of overhead camshaft. The new power plant has 2⅞ by 5 in. cylinders and is stated to give a speed from 2 to 75 m.p.h. when fitted to a passenger car chassis. The cylinders are cast in two blocks of six each with the motor heads cast in a single block for each set of three cylinders. A liberal use of aluminum has been made throughout the motor, the crankcase being vided aluminum design and the pistons also of aluminum

Lightness is one of the main features connected wit new motor, and this has been carried through particular the reciprocating and oscillating parts. In addition to a num pistons seamless steel tubular connecting rods aid i reduction of vibration at high speed. The crankshaft i in. in diameter and the flywheel is a steel forging. Lul tion is by pressure feed. It is intended to put these m through on a regular production schedule.

British Give Cars for Ambulance Work

Donated Passenger Cars Converted Into Field Trim and Turned Over to French Military Drivers—Formed In Convoys of 20 to 40—50,000 Wounded Carried in Vosges Mountains

PARIS, Aug. 1—In the brief interval between a trip to the front, from which his automobile returned with a bullet hole through the front fender, and a visit to an artillery factory where experiments were made with new explosives, President Poincaré formally inspected a fleet of ninety automobile ambulances presented by the Automobile Association and Motor Union of Great Britain to the French army.

The ceremony took place in the courtyard of the Invalides with the golden dome of Napoleon's tomb as a background and captured aeroplanes and cannons as decorations. The audience was capable of being produced by war alone: French soldiers and officers in a variety of uniforms; English staff officers in khaki; American ambulance men in the same colored cloth; burly Russian officers; Belgians in the new khaki uniforms which appeared to have been borrowed for them; and English civilian officials in immaculate top hat and frock coat.

All Private Touring Cars

For several months the Automobile Association and Motor Union has been making appeals to its members for automobiles or subscriptions to buy automobiles to be presented to the medical service of the French army. The number of persons who must have parted with their cars is considerable, for the ninety machines inspected at the Invalides represented only a portion of those put into service under these conditions, and they had all been private touring cars. Every European make was represented—English, French, Italian and German, with English predominating. The passenger car bodies had been stripped off and replaced by a uniform type of ambulance body carrying four men lying or eight sitting.

French Drivers Take Charge

The English effort comes to an end with the delivery of the ambulances to the French army authorities. Each car is put in charge of a French military driver and convoys of twenty to forty are formed with the necessary officers taking their orders from the chief doctor. The ambulances are sent out to different points just to the rear of the battle line, where they are made use of in carrying wounded from the dressing stations to the clearing hospital. Except in very rare cases, these automobiles are not used for long trips. They are employed as auxiliaries to the railroads: bringing men from the dressing stations to the military hospital; carrying them from the hospital to the hospital train; taking men from the train to the base hospital. Wherever they are placed the work is apt to be spasmodic. For a week or more there may be nothing to do, then, following fierce fighting, men and machines may run backwards and forwards without a stop for 48 hr. or more.

One of the features of the English automobiles is a very successful type of traveling kitchen mounted on a 30-hp. Fiat chassis. It is designed to handle big quantities of light refreshments, such as coffee, tea, cocoa, bread and butter, etc., to the men who have just come out of the firing line, are temporarily cut off from their food supply, or have come off a long railroad journey. Across the front end of the body is the cook stove, with kerosene as fuel, and the washing sink to which water is pumped from a tank; down each side is a table with food cupboards beneath and plate and mug racks above; across the rear is a folding counter over which the food is passed to men outside.

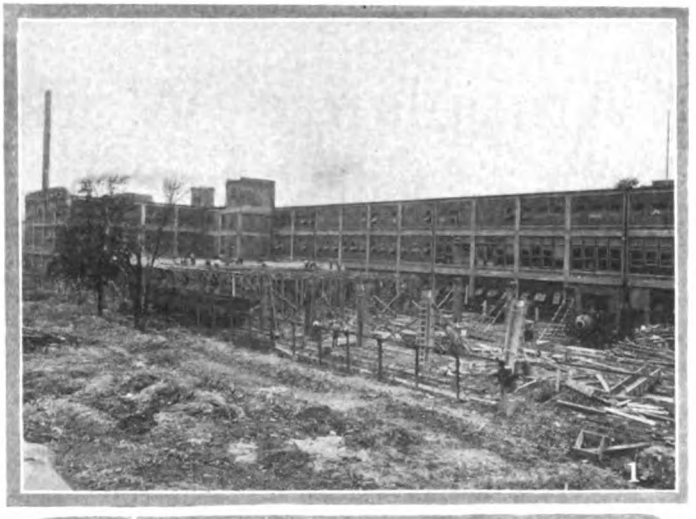
English automobile ambulances in courtyard of Invalides, Paris. In the background are captured aeroplanes and cannon. Here President Poincaré of France formally inspected the ambulances

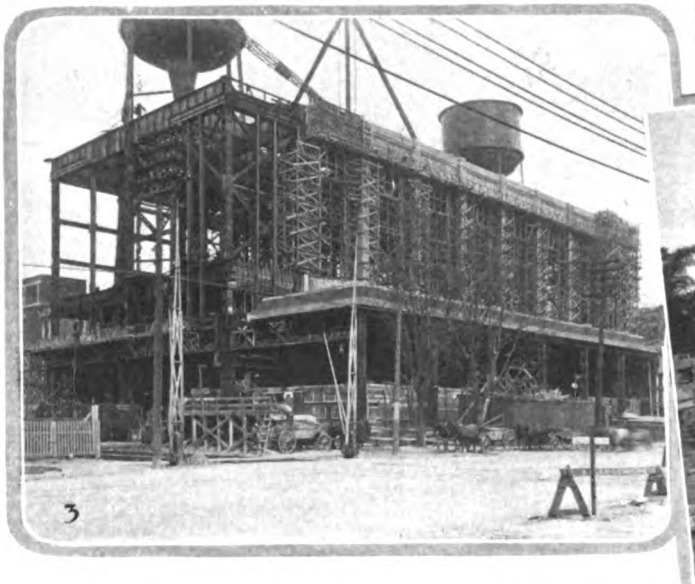
In the Vosges mountains, where railroads are scarce and the automobile is the only reliable means of locomotion, there are twenty-four sections of British ambulances with the French troops. In this district all the work is done over high mountain passes. Since these automobiles went into service towards the end of last year they have carried more than 50,000 wounded.

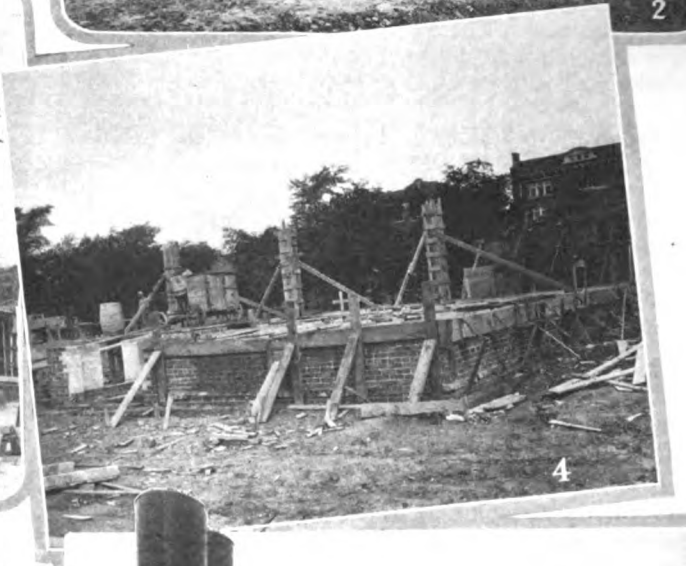
Regularly Inspects Cars Sold

LOUISVILLE, KY., Aug. 14—The Southern Motors Co., this city, agent for the Packard, Hudson, Dodge and Detroit electric employs an inspector who makes periodical inspection of all machines sold by the concern. During the first year that the car is in the hands of its new owner, this inspection is made free of cost. Repairs which in the wisdom of the company appear to be owing to the owner also are made without charge. A nominal sum of $3 is charged for inspection after the first year.

Detroit Plants Mak







1—$200,000 addition to assembling plant of Paige-Detroit Motor Car Co.

2—Dodge Bros. test shed, storage and final car inspection. One of many additions to this company's factory

3—Ford Motor Co.'s new power house, which with equipment represents an expenditure of between $2,000,000 and $2,500,000

4—Hyatt Roller Bearing Co. new office building for automobile division only. It will cost $60,000

5—Beginnings of Timken-Detroit Axle Co.'s new drop forge plant, which will cost $240,000

DETROIT, MICH., Aug. 16—The prosperity of the concerns centering about Detroit engaged in the manufacture of automobiles, trucks and accessories is such that twelve concerns have either finished or are about to complete additional buildings which will provide more than 850,000 sq. ft. additional floorspace. The cost of these additions is well up toward the $5,000,000 mark, according to the estimates given by the twelve concerns, eleven of which total to $4,546,000.

The concerns included in this total are the Packard Motor Car Co., Paige-Detroit Co., Timken Axle, Chalmers Motor, Rands Mfg. Co., Federal Motor Truck, Hyatt Roller Bearing Co., Ford Motor Co., Hudson Motor Car Co., Dodge Bros., Kelsey Wheel Co. and Continental Motor Mfg. Co. The additions in detail are:

Paige-Detroit Motor Car Co.—Addition to assembling plant and also warehouse for materials in the same building. Will be 4 stories high, 312 by 64, or 74,880 sq. ft. Was started in July, to be completed in November. Expenditures about $200,000.

Total floorspace of plant will be 464,880 sq. ft.

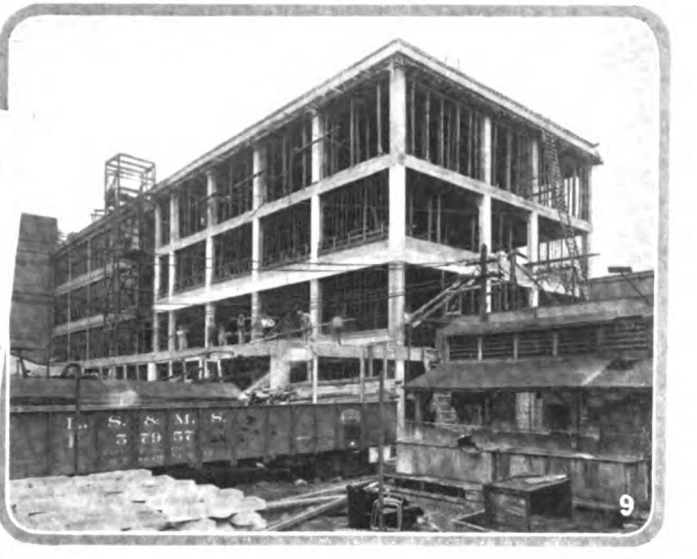
Dodge Bros.—Test shed—storage and final inspection of cars. One story, 380 by 60, 22,800 sq. ft. Started in April, completed in August, to cost $25,000. Additions to Dodge plant have been under way since last year and represent an expenditure on buildings alone of several hundred thousand dollars.

Ford Motor Co.—Power house, 250 by 150. Started in April, 1914, will be at least 6 months before completed. Building to cost about $1,000,000. With full equipment power plant represents an investment of between $2,000,000 and $2,500,000.

Hyatt Roller Bearing Co.—General office building for the automobile division only. Three stories high, 100 by 60, or 18,000 sq. ft., to cost $60,000. Started in July, to be completed in November.

Timken-Detroit Axle Co.—Where new drop forge plant will be located. One-story building, having 16,100 sq. ft. floor-

$5,000,000 Additions



6—Top, body and finished car building and employment department structure which form part of the Hudson Motor Car Co. $1,000,000 additions

7—Truck assembling and machine additions to the Packard Motor Car Co. factory

8—Service and stock department addition to Federal Motor Truck Co. plant

9—Addition to Chalmers Motor Co. machine and manufacturing building, one of several instances of expansion at this factory

10—Windshield plant of Rands Mfg. Co. is adding 20,000 sq. ft.

space. Will cost when completely equipped $245,000. Started in May, to be completed in September.

Other additions to plant being erected. Expenditures on buildings alone $225,000.

Hudson Motor Car Co.—Large building in rear, three stories, 500 by 60, 90,000 sq. ft. To be top and body and finished car building.

Building in front, three stories, 400 by 60, 72,000 sq. ft., to be employment department on first floor, addition to machine shop second floor, and third floor undecided. Work started in May, to be ready in October.

Present other additions to Hudson plant include an additional floor to all two-story buildings and also the lengthening of these buildings. There is also to be a new six-story building. Total expenditure on buildings and equipment is to be between $1,000,000 and $1,500,000.

Packard Motor Car Co.—In the foreground is a steel frame shed addition to the assembling truck department, 240 by 240, or 57,600 sq. ft. Building in rear, addition of one floor 240 by 60, or 14,400 sq. ft., to truck machine building.

Total additions to the Packard plant will give 377,000 sq. ft., and bring the total of the plant to 48.1 acres of floorspace. Additions were started in June and are to be completed in November, and the cost will be about $550,000.

Federal Motor Truck Co.—One-story addition, 168 by 60, or 10,080 sq. ft., to be used as service and stock room.

Chalmers Motor Co.—Four-story addition to the machine and manufacturing building. Will total 24,300 sq. ft. of floorspace. Started in July, to be ready in September. Cost about $40,000. Other additions to plant will make total cost $125,000 and increased floorspace all told 50 000 sq. ft.

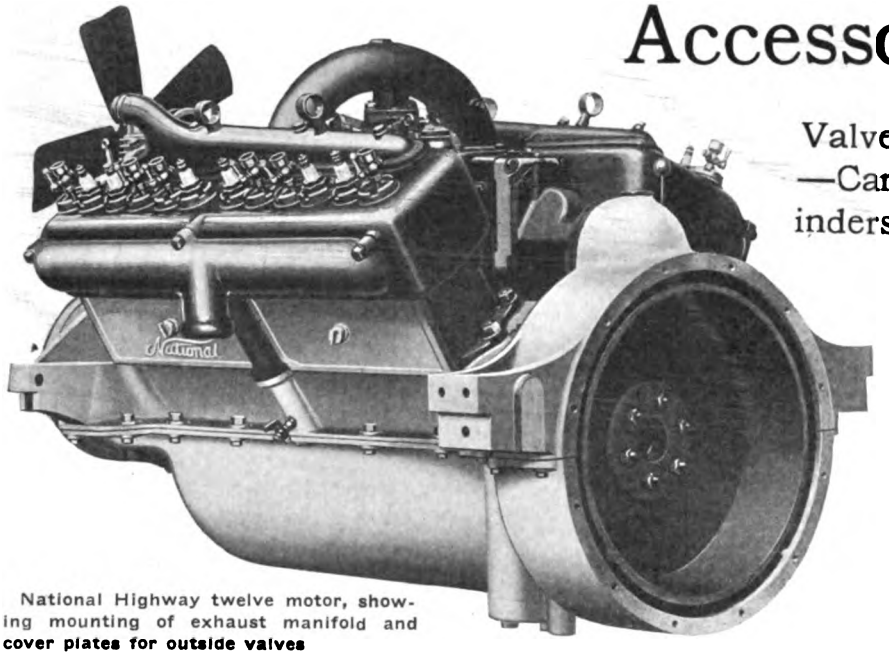
Rands Mfg. Co.—Two-story addition, 153 by 65, 20,000 sq. ft. floorspace to windshield department. Started in July, to be completed in September. Expenditure $26,000.

Kelsey Wheel Co.—Adding a new press and stamping building, 325 by 80, and two floors on another building, all told 78,000 sq. ft., to cost about $250,000.

Continental Motor Mfg. Co.—Additions are being made to the assembling room, block test department and heat treating department. With other additions, these represent 55,000 sq. ft., the cost of the buildings being $150,000.

National Twelve Valves Outside—Accessories in V

Valves Thus Rendered Accessible —Cantilever Rear Springs—Cylinders Have Separate Oil Feed



National Highway twelve motor, showing mounting of exhaust manifold and cover plates for outside valves

A NATIONAL Highway twelve has been on the road for many months and a few privileged persons were taken out in it, by the National Motor Vehicle Co., Indianapolis, Ind. Like other V-type multi-cylinder motors it has a great high-gear ability and combines smoothness with rapid acceleration in a marked degree. The car has all the character that has made the National six what it is to-day after 10 years of development, only it has a good deal more power in proportion to its weight.

The motor is not so very large from a volumetric viewpoint, being 2.75 and 4.75 bore and stroke, giving a piston diplacement of 338.5 cu. in. and an S. A. E. rating of 36.26 hp. The wheelbase measures 128 in. and the body, of standard touring type, is seated for four, with folding seats for two more. The manufacturers describe it as providing ample room for six passengers and close room for seven.

Accessibility Conspicuously Good

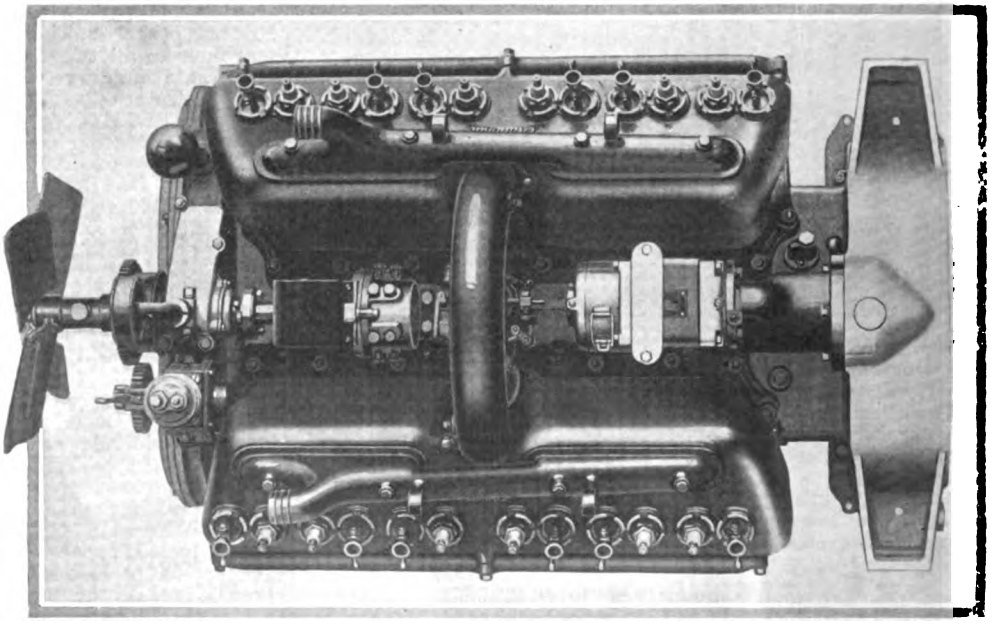
The motor embodies all the best features of modern high-speed design and the use of outside valves; the first example in V designs was suggested by the much better accessibility given by this position, and by the convenience of having the electrical gear and other motor accessories in the V, where their individual accessibility is maximum.

The cylinders are cast in blocks of six and are of conventional L-head design with small combustion chambers. Two camshafts are necessary, but there is no need for rockers or other devices to synchronize the valve action, as the valve operation for either set of cylinders is totally unaffected by the other set. At the front helically-cut timing gears drive the camshafts as in a T-head motor with vertical cylinders, and for the drive to the Splitdorf magneto a silent chain runs from the right camshaft to the fan pulley spindle. This magneto is a special Splitdorf.

In the rear of the V is the Westinghouse starting motor, and the generator is located alongside the crankcase, being the only attachment not within the V. For the connecting-rods the side-by-side design has been chosen, the cylinder blocks being staggered 1 in. to permit of this.

The lubrication system is unusually complete as there is practically no moving part that does not receive a direct supply from the pump. The latter, a gear type, is located in the oil base, having a large screen on the suction side and also a gauze strainer in the form of a tray covering the whole top of the oil pan, but there are no dip troughs as the crankshaft is fully drilled and the oil from the main bearings finds its way to the connecting-rod lower ends.

Separate pipes lead to the timing gears and to each of the camshaft bearings while the piston pins are oiled by an inversion of the usual method of fully forced lubrication systems. As a rule the connecting-rod serves to carry the oil to the wristpins and then to the cylinders, but here the oil feeds to each cylinder at a point about 1½ in. from the

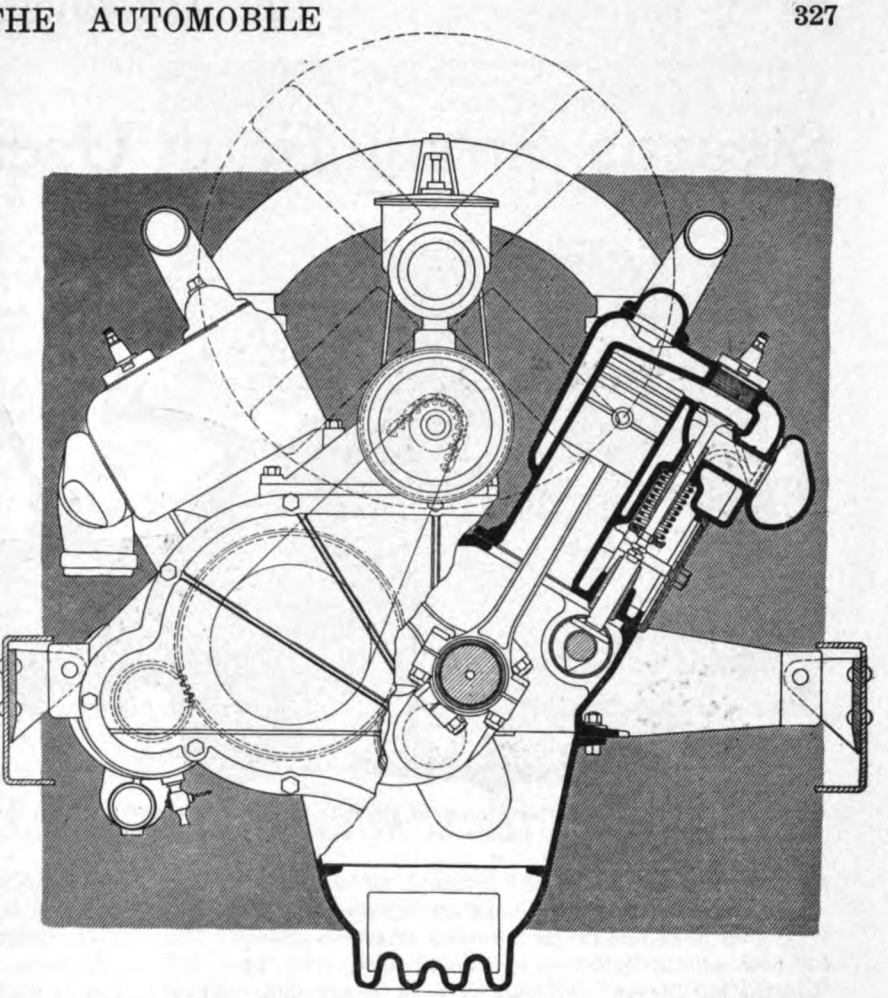


Plan of National twelve showing mounting of the carbureter and electric units in the V with transverse intake manifold. Note water outlet manifold mountings

bottom and reaches the wristpins through tiny holes drilled in the aluminum pistons. The latter have a V groove cut near the bottom, which is used to lift oil into the cylinder, as the absence of splash troughs in the body of the crankcase cuts down the amount of spray present. As to the oil pressure, this is not very high, the relief valve blows off at 25 lb. per sq. in. When the engine is idling the pressure is about 10 lb., and it rises gradually with the speed till the limit is reached.

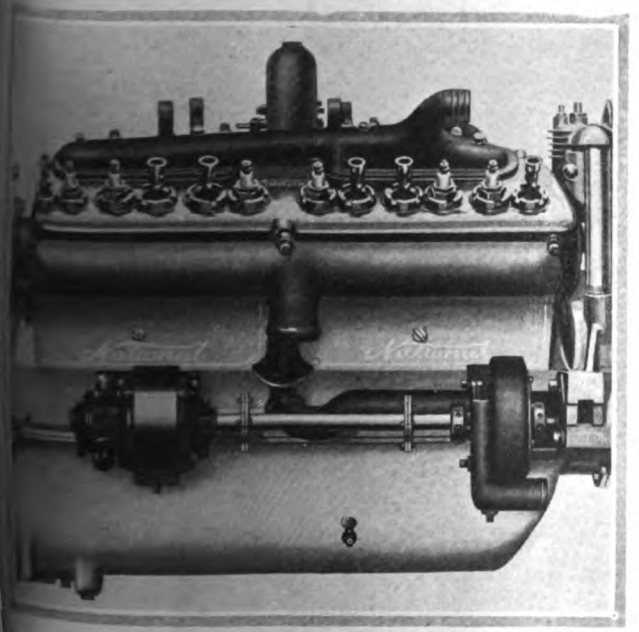
There is only one water pump, but this is duplex internally, the rotating member carrying two sets of vanes. One set feeds directly upward into the block of cylinders on the right and the other half of the pump delivers through a passage cast in the aluminum of the crankcase to the left block. This cuts down the piping materially and makes for efficiency and simplicity.

A few other facts about the engine that are interesting may be given, as for instance the weight of the pistons, which is 8 oz. without rings. The valves are 1 5/16 in. diameter and the lift is ⅜, giving a quite large opening, while the mushroom tappet provides a quick lift and descent, giving a slightly better valve diagram than the roller type. It is probable that the fan has some effect as a damper to the crankshaft, though it is doubtful whether any such aid to elimination of vibration is needed, but the short fan drive, when kept tight, provides a flywheel just as the Lanchester device, with a slipping possibility. Of course reaction from the fan would be cushioned a good deal by the belt and not the chain, but it is an undoubted fact that the presence of a fairly high speed fan does often have a steadying effect on a motor.



Section through National twelve, showing how the outside valves are actuated and also giving an idea of the water jacketing space and exhaust manifold mounting

Aft of the motor there is little in the chassis, if anything, that differs from the Highway six described in THE AUTOMOBILE for May 27. The clutch is an aluminum cone with leather face and the unit gearset provides three forward speeds, all shafts therein running on annular ball bearings. The propeller shaft is tubular and bears two universals, and the rear axle is floating. On both the six and the twelve a flat cantilever rear suspension is employed and it may be noticed that the center bracket has the swivel pin located beneath the spring, instead of above it as is more usual. The springs are 51 in. long and 2½ in. wide with eight leaves each and their action is extremely satisfactory. The front springs have no noteworthy peculiarity, being 38 in. long by 2 in. wide, but special precautions have been taken in laying out the steering and the use of large ball thrust bearings for the front axle swivels makes the steering control very facile.



Right side of National twelve, showing mounting of pump and generator, the only motor accessories not located in the V

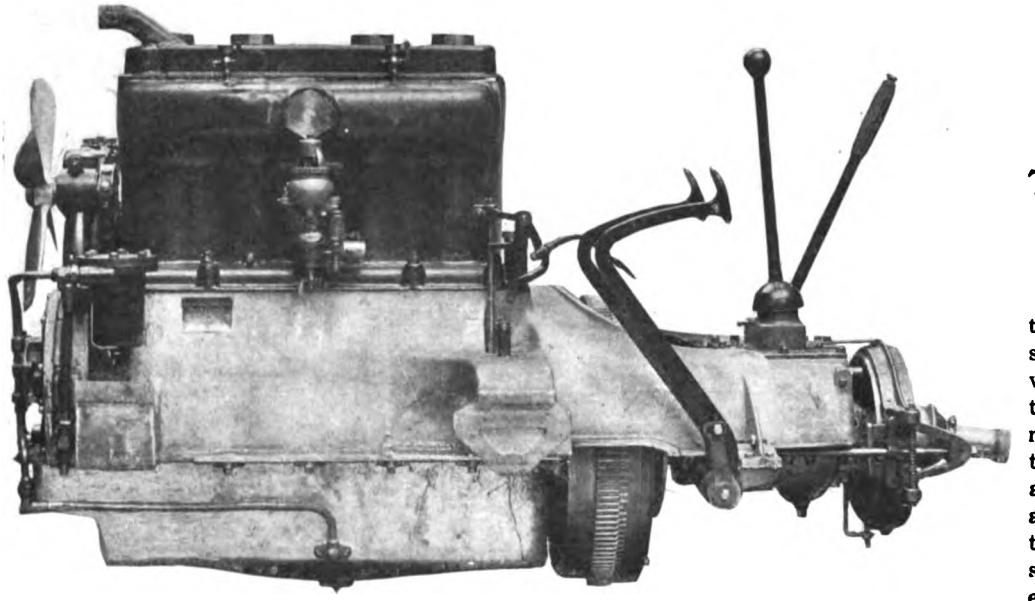
Throughout the rear axle taper roller bearings are used, and the type is floating, very strong steels being used so as to cut the weight as much as possible. This statement applies to the whole chassis which has few redundant parts and very little dead weight in any portion. Drive is by spiral bevel and the top gear ratio is 4.4 to 1. It should be added that the twelve-cylinder engine is made throughout in the National plant at Indianapolis as the shops are well equipped for the production of a moderate number of high class motors.

Brakes 15 by 2 In.

In general the body is like that which drew so much comment at the national shows this year, having the divided front seats and the smooth lines which the National company was among the first to introduce to America. Without the least hesitation it is safe to say there is no car in Europe that is better appearing than the touring National, either six or twelve, and for comfort it can vie with the best. In equipment the car is well provided, having speedometer, one-person top and all the usual accessories, while the four tires are each 36 by 4½ in., which should be large enough for the high power, when the light weight is remembered.

Stearns Small Four Uses Westinghouse

Battery Ignition Adopted— Torque Rod Stronger —Price Now $1,395



Stearns small four power plant, showing oil filler beside fan bracket. Also contracting service brake operating mechanism. The brake is mounted behind the gearbox

THE F. B. Stearns Co., Cleveland, Ohio, created a good deal of interest a year ago by introducing a new small four at $1,750, the design being extremely modern. This car now sells at $1,395 as announced some weeks ago. For 1916 the big Stearns development is to be the eight-cylinder with Knight engine which will be ready shortly, but meanwhile the small four has been put into regular production and the factory is ready to deal with it in quantities. Building extensions which were commenced in the early spring have been completed for some time and the much needed additional space is now fully occupied.

It is the getting into stride with the new four that has enabled the drop in price to be made as quality has not been cut in either chassis or body. There are three changes, the most important being the employment of a Westinghouse two-unit system of electrical equipment and the adoption of battery ignition and the other a small change in the design of the torque rod which increases its strength by giving a larger bearing at the front end where the forward extremity is secured to the frame by a spring hanger.

Complete Lubrication

The motor, 3¾ by 5⅝, has a displacement of 248 cu. in. and an S. A. E. rating of 22.5 hp. This figure does not represent the true power as the long stroke produces a much higher piston speed than the 1000 ft. per min. on which the formula is based. A neat block casting is used for all four cylinders, and the engine has the fully forced system of lubrication introduced last year. Oil is pumped to the three main crankshaft bearings and thence passes to the crankpins. From here it is led up the hollow connecting-rods to the wristpin bushings, while spray of escaping oil from the various bearings cares for the sleeves and the other motor parts. It is proved by the records of the company that bearing troubles are very uncommon with Stearns cars as the number of replacement bushings asked for is extremely small, and, of course, this is a direct measure of the efficiency of the lubrication.

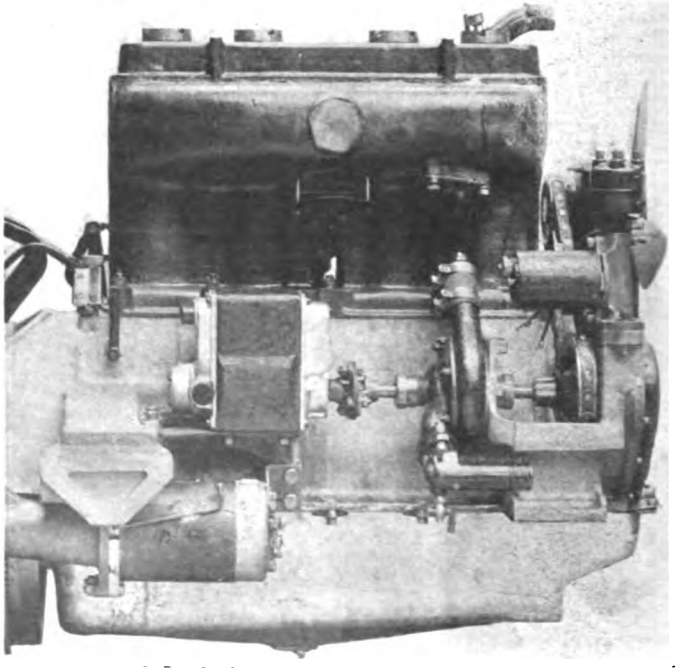
Another change is the substitution of timer ignition for the magneto originally used, the distributer being situated at the front of the engine beside the fan bracket.

Mention of the fan draws attention to a very ingenious small feature of Stearns design which is that the lubrication of the fan spindle is automatic. It may be seen in the illustrations that the oil filler is located alongside the fan bracket and all oil for the motor is put in through this cap. Inside the strainer is a wick having one end in connection with the fan bushing, and this wick becomes saturated with oil each time the crankcase is filled, so attending to the fan lubrication with sufficient frequency.

The location of the generator and the starting motor are also shown in the illustrations, and it needs only to be added that the latter has a Bendix flywheel engagement. The oil pump is located at the front end of the eccentric shaft, and a silent chain is employed for the generator and water pump drive.

Transmission Brake a Feature

The clutch is a leather-faced cone with powerful cushion springs to make the engagement gentle, and a really adequate clutch brake is fitted to make gear shifting as easy as possible. Actually the gears are extremely easy to handle



New Westinghouse electrical equipment of the Stearns light four

though the low-speed ability which is characteristic of the Knight motor makes the high gear available for nearly everything.

One of the most successful features of the Stearns light four has been the contracting brake behind the three-speed gearbox, this having extremely smooth action combined with great power. In the left side view of the power plant the action of this brake operation is shown clearly. The two shoes hinge on the opposite sides of the drum and their free ends bear small rollers. Inclosing these rollers is a triangular, hollow cam which depression of the pedal pulls forward, so closing together the ends of the brake shoes. The separating spring spreads the shoes and also puts a light release load upon the rollers, the cam, and so to the pedal, the effect being that there is no point in the whole of the brake layout where slack can develop and the creation of a rattle is thus impossible. The emergency brakes are of expanding type.

Spiral bevel drive is employed and the axle is a floating construction containing a very full equipment of radial and thrust ball bearings, while a torque stay of pressed steel takes the driving and braking torsional stresses. Propulsion is through the springs which are 50 in. long by 2½ in. wide and of cantilever type: the wheelbase is 119 in.

There are five body styles to choose from, a five-passenger touring car, roadster, three-passenger cabriolet, sedan and seven-passenger limousine. Roadster and touring car both cost $1,395, the cabriolet $1,900, and limousine $2,500. As to equipment this is complete and of the best quality. The upholstery is hand buffed leather and all the body fittings are the highest class.

Stearns-Knight small four which lists at $1,395

Lighting is cared for by double-bulb headlights, tail light and a cowl board bulb. Four 34 by 4 tires are used with a spare demountable rim. The carbureter is made specially for the Stearns motor and fed by gravity from a cowl tank.

Cameron Six Touring or Roadster $1,000

THE Cameron Mfg. Co., New Haven, Conn., will produce for 1916 a six-cylinder chassis of 122-in. wheelbase and 33 by 4 wheels with two styles of body, a five-passenger touring and a runabout with an inclosed seat in the rear which makes it in reality a four-passenger car when opened.

The motor is 3 by 5 block design of conservative construction. At a speed of 2000 r.p.m. it is stated that 40 hp. is delivered on the block and the weight of the motor is said to be less than 9 lb. per horsepower. The crankshaft is carried on three bearings and is 1¾ in. in diameter. The bearings are all bronze backed with nickel babbitt lining. The connecting-rods are 9 in. long with their lower bearings 1¾ in. in diameter by 2 in. length. The upper bearings are ⅞ in. diameter with 1¾ in. length on the wristpin.

Lubrication is taken care of by a plunger pump operated from the camshaft which takes the oil from the compartment in the lower part of the crankcase to an oiltight compartment surrounding the camshaft. The pressure is sufficient to hold the valve lifter against the valve, thus even with clearance the clicking of the tappets is avoided.

The one-piece camshaft is driven from the crankshaft by helical gears of eight-pitch with 1-in. face. The camshaft gear is bolted to a flange forged on the end of the camshaft. The water pump is gear-driven and the shaft extends through to drive the Atwater Kent timer distributer for ignition.

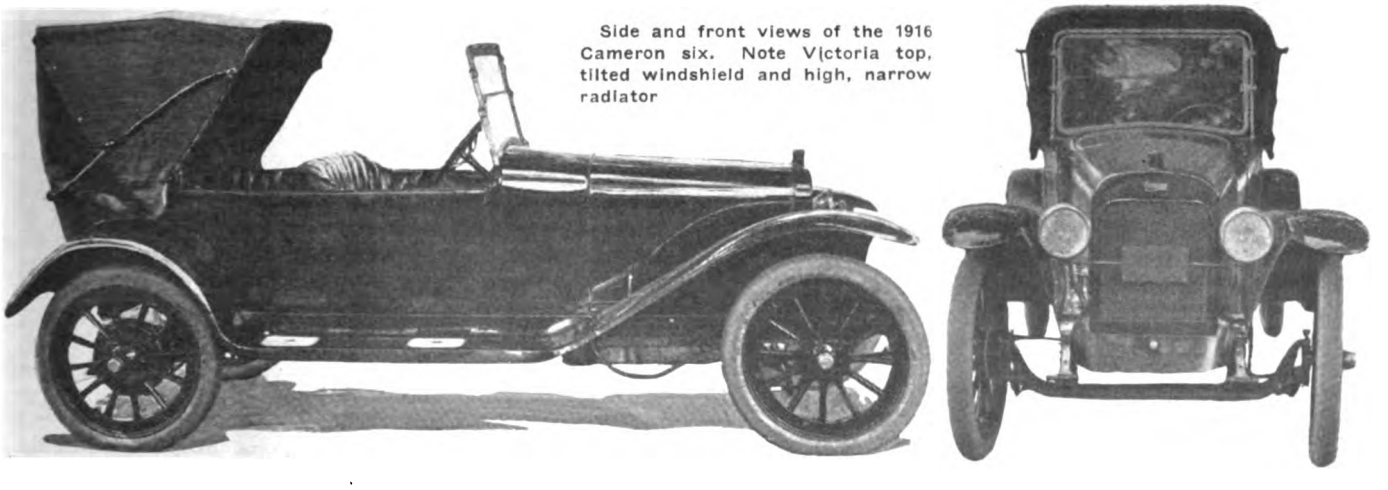
A Splitdorf-Apple starting and lighting system is provided in which a single unit motor generator mounted at the front of the crankcase is driven by silent chain inclosed in the gearcase. The starting switch is the flywheel housing.

Fuel is carried in the tank contained in the cowl, giving a direct gravity feed to the carbureter. This instrument is a 1¼-in. Zephyr and can be primed or adjusted from the seat.

The clutch is an aluminum cone faced with special tanned leather and inclosed in a housing which carries the pedals and receives the radius tube from the rear axle upon which the three-speed gearset is mounted.

The rear axle is floating and the bevel drive and differential are mounted on annular ball bearings and the drive at this point provides a reduction of 3.75 to 1. The two foot-operated brakes are 12 in. in diameter.

The windshield is tipped back on an angle of 15 deg., and the car is provided with a Victoria top over the rear seat which can be thrown back if desired or fitted with curtains which fasten to the windshield in rainy weather. Both touring and roadster are fully equipped and sell for $1,000.



Side and front views of the 1916 Cameron six. Note Victoria top, tilted windshield and high, narrow radiator

Aluminum in Automobile Chassis

Saves Weight Cheaply—Steel Prohibitive on Price

By A. Ludlow Clayden

DETROIT, MICH.—Editor, THE AUTOMOBILE—There were some remarks in the letter from Finley R. Porter published last week which I, as author of the article on the uses of aluminum, would like to reply to directly. Mr. Porter's main contention is that it is possible to make the lightest automobile by the use of the strongest material only; that is by using steel for everything. As a broad statement this is undeniable simply because if a given *strength* is required high tensile steel of a modern sort will give us the machine with least weight, because steel is stronger than aluminum in a greater ratio than aluminum is lighter than steel.

Efficiency at High Expense

From the efficiency standpoint also, he is probably correct in saying that the most highly efficient motor is obtainable by a generous use of steel. The racing Mercedes which has an all steel engine will probably stand long continued high speed better than any other motor ever built. This motor is practically identical with the Mercedes aeroplane engine that is accepted as being the best in the world to-day. But such an engine is extravagantly costly.

I do not wish to go too greatly into detail, but to mention the cylinders as perhaps the most debatable part, it is thought by many engineers that the success of the Mercedes motor is the even thickness of all its parts and the even cooling that must result therefrom. The steel cylinders of this engine are machined all over, both inside and outside, and cost more apiece than a whole motor of simpler construction. With the aluminum motor the cylinder liner can be steel just as well as cast iron, and there is no necessity to back it with aluminum, the outside of the liner might be in direct contact with the water, so avoiding the junction which, as Mr. Porter rightly points out, is a poor conductor. But it is not the cylinder that gives trouble through getting hot; rather it is the valves and the valve seats. Again, in the Mercedes motor the even cooling of these parts is obtained by the method of machining the cylinder all over and then attaching a sheet steel jacket by welding, a perfect way of doing it but prohibitive for ordinary manufacture. If the valves are contained in the head of the cylinder and this head is aluminum we have better cooling than cast iron would give, and much less weight, for but a tithe of the expense demanded by the all steel construction.

Then, turning to more general matters, in many automobile parts the strength of steel cannot be utilized because we require *rigidity*. Take a crankcase as an example, this could be made very light from steel in the form of sheet and wire or tube. By putting in a tubular member to care for each stress and welding up perhaps a hundred pieces the result would be wonderful, but using a much less strong metal like aluminum enables almost the same weight to be attained with an infinitely greater simplicity.

On the subject of aluminum pistons Mr. Porter makes a very definite statement which is not in agreement with the experience of several other engineers. The only possible explanation, to my mind, is that Mr. Porter has not had the opportunity of trying the best sort of aluminum piston or that the design of those he has used has been faulty in some way. The outstanding fault of the steel piston is that when made thin enough to be light it has so narrow a section that it cannot keep cool, and consequently the head reaches a destructively high temperature. With aluminum the thicker section and the better conductivity enable the same reciprocating weight to be attained with much smaller likelihood of trouble, at least such is the experience of many engineers.

It must be realized, however, that sand cast aluminum and die cast aluminum are two very different things. Pistons which fail when sand cast can often be made lighter still in permanent mold form and stand up under treatment much more severe. Similarly with such chassis parts as axle cases. Steel will give the *strength* but not the *rigidity* unless it is thicker than the strength requirement demands, and here too there is a vast difference between sand and die cast aluminum.

With respect to the porosity question raised by Mr. C. C. Hinkley, I would call attention to the fact that Mr. Hinkley bases his criticism on experiments made in 1906, Aluminum to-day is not the same substance as it was then. There are two ways of overcoming the porosity and the best is by die casting. The other is to do as is now done with the experimental aluminum cylinder castings, treat the interior surfaces with a sort of enamel, but once a pattern is selected and got into proper repetition shape there should be no trouble on this score.

In conclusion, I hold no special brief for aluminum and where money is no object whatever the extensive use of steel is undoubtedly desirable, but money is always an object in motor car construction so if we are to make the *average* automobile lighter and keep its price within bounds the use of light material wherever possible seems a better proposition. We can substitute aluminum for cast iron almost everywhere throughout an automobile chassis, without increasing the section, and still have strength and to spare. Design is unaffected, machining is simplified, up-keep cost is reduced, and the extra cost is almost nothing when everything is considered and balanced up.

Expansion Not a Trouble—All 1917 Cars Will Have Aluminum Pistons

By James E. Diamond

Editor, THE AUTOMOBILE—I have read, finding most interesting, Finley R. Porter's contribution to the current issue of THE AUTOMOBILE in which he takes exception to certain premises and conclusions drawn by A. Ludlow Clayden in his recent story Cutting the Weight, in which the more generous use of aluminum is advocated. In a great many ways my views are quite at variance with those held by Mr. Porter, and with exactly the same purpose influencing that gentleman to enter the discussion, I would like to point out wherein I differ with him and endeavor to show why.

Weights of Aluminum and Steel

In the first place, aluminum is not one-third lighter than steel or cast iron, but rather is only one-third its weight, that is, the ratio is not two to three, but one to three. In the second place, I think your contributor has underestimated

the strength of properly manipulated, properly alloyed aluminum. Its strength is greater than that of ordinary cast iron by 3000 or 4000 lb. For purposes of comparison let us assume its strength 20,000 lb., a low figure I am inclined to think that the steel that would be used in most places in an automobile, especially about the motor, would not have a strength of 120,000 lb., which figure is arrived at by assuming the correctness of your contributor's statement that the strength of aluminum is but one-sixth that of modern steel. While alloy steels are much stronger than this, I should judge that the strength of the steel that would be used in most places about a motor would be nearer 60,000 lb. If this is true it immediately follows that a section in aluminum may be three times as heavy, and yet not weigh more than a steel section of equal strength. The question of rigidity here enters. It is undeniable that in many locations about an automobile rigidity is of as much importance as strength. I do not believe there can be any question that in the hypothetical case just mentioned that the aluminum piece would have the greater rigidity.

The Price Question

Mr. Porter grants that "In the case of a low-priced automobile with a comparatively low range of efficiency required, the generous use of aluminum would, without doubt, result in a material gain in efficiency, both in upkeep and roadability." It would seem to me that if this is true in the case of the low priced car, it certainly must be true in the case of the higher priced one.

While the discussion can only remain an academic one, my impression is quite the reverse of Mr. Porter's, relative to the result were two designers of equal ability given free rein to design an automobile of given capacity—it being understood, of course, that each car was to be a commercial proposition, from the standpoint both of price, and of production possibilities—the one to confine himself to the use of steels, and the other free to use aluminum, cast iron, and the milder steels. I am absolutely of the opinion that the latter would produce as light, if not a lighter job, and certainly one better commercially. Further I believe the designer could go over the all steel job and improve it by the use of aluminum in certain places.

Concerning the motor proper, it is stated that the first great handicap is the vast difference in the rates of expansion between aluminum and iron, this prohibiting the employment of sleeves. Incidentally the difference is not so great, after all, being not quite two to one. However, at first glance, it might seem that the point was well taken, but careful analysis I think will show that the part that this really plays is not very significant. As having a bearing on this, let us consider the methods of inserting the sleeves. One method is to machine the sleeve, and bore out the cylinder to exactly the same size, using an arbor press to force the sleeve into place. The other method is to heat the cylinder block to as high a temperature as practicable (higher than the block would ever get in service) then pushing the sleeve into place. It would seem to me that there must be initial tension in both cases between sleeve and cylinder, and that for all practical considerations space between is non-existent, hence a perfect thermal connection between sleeve and block. Since the conductivity of iron is so much less than that of aluminum, much of the heat due to the explosion is going to be retained in the sleeve, with the inevitable result that the sleeve is going to expand. On the other hand, the cylinder wall receiving the overflow of heat from the sleeve is dissipating this heat into the surrounding water, consequently at all times remaining a great many degrees cooler than the sleeve, enough so in fact, not only to equalize the difference in expansion but even to increase the tension existing between sleeve and cylinder. The greater the range of temperatures in the motor the more favorable the conditions for this type of construction. However, after all, theory for and theory against, may be put aside since there is concrete evidence that this sleeve construction is entirely feasible. Experience has shown that the sleeves become loose at no time, remaining securely in place after long continued service.

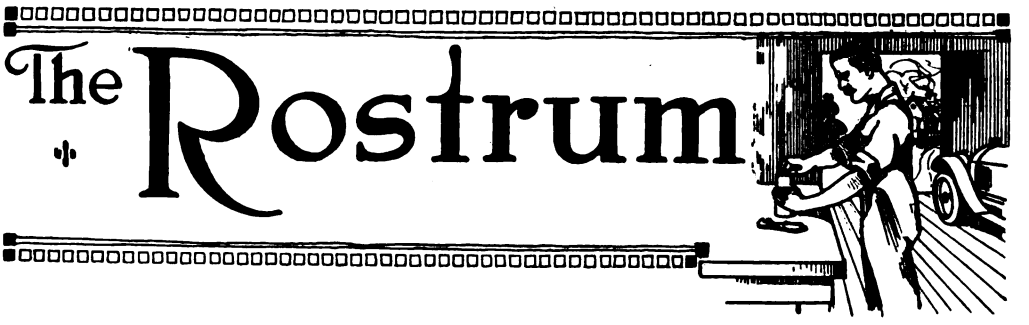
The appreciation is general that light weight is at a premium in the aeronautical motor field, and that expense is a decidedly minor consideration. In the light of this, it may perhaps be interesting to know that aeronautical motor manufacturers have taken a lively interest in the aluminum motor, and I believe that an announcement relative to an all-aluminum aviation motor will shortly be made by one of the manufacturers of the highest grade motors in this country.

Little may be added about aluminum alloy pistons. Mr. Porter has apparently not had the success with these that most others have had recently. There have been problems in connection with the aluminum piston, but these have been gradually worked out, until it looks as though aluminum alloy pistons would be standard equipment on practically all cars by 1917. The steel piston I do not believe will ever become a commercial proposition; its cost must necessarily always be high, and I have heard of disastrous experiences with this type. As a measure of the success of Lynite pistons, I may say that my company has in hand orders for approximately half a million pistons to be made by the Kotheas process.

I hope that I may be permitted a little more space to consider briefly also the case that Mr. Hinkley makes against the use of aluminum as a material for motors due to the fact that the alkaline waters prevalent in certain sections of the country caused rapid deterioration of this metal. At the time Mr. Hinkley noted this unfavorable condition, back in 1906, aluminum foundries did not know very much about aluminum, and handled it the same as brass was handled. It is doubtful whether the foundry with the, at the time, most advanced methods and practices, could have made a success of the job in question—a crankcase with the gear pump housing integral with the casting—with the alloys and methods then in use, and it is almost if not a certainty that any other foundry would have made a failure of the attempt. I believe that every engineer appreciates the wonderful strides made in the art of casting aluminum, for science it is. The job in question would not offer any particular difficulty to-day. In fact, castings are being made to-day that a year since we should not have undertaken. This question of alkaline waters was considered when the first aluminum motors were built, and to answer which several of these first motors were put in cars and shipped to the alkali regions for test. The first of these have been running for 2 years, and are apparently as good as the day the motors were built. I have yet to see the first aluminum intake manifold returned on account of porosity due to the action of alkaline waters.—JAMES E. DIAMOND, Engineer, Aluminum Castings Co.

Automobiles Raise Texas Land Values

AUSTIN, TEX., Aug. 13—Bankers and business men generally who have been taking an inventory of land values in different parts of Texas recently claim that the automobile is more largely responsible than any other one factor for the increase in the prices of farm and ranch properties during the last few years. The improved mode of transportation has brought the towns and the country into close touch with each other and has made living in the rural districts much more worth while than formerly. In some localities, it is estimated that the increase of land values, due to the automobile, averages more than $15 per acre. The general average increase of values, taking the State as a whole and embracing about 168,000,000 acres is placed at $5 per acre, or a total increase approximately of $840,000,000. This increase is exclusive of that which is credited to ordinary growth.



Must Not Stretch Perfection Piston Rings

EDITOR THE AUTOMOBILE:—I have recently put a 4-in. Perfection piston ring in my Buick 31, 1913 model. The car had been run about 800 miles. I used five of these small rings to each cylinder, using the old ones for the other two grooves. The compression seems to be greater than it was before I put these new rings in. The mechanician that put these rings in for me said that they would not damage my cylinders, but I have had several mechanicians since then to tell me that they would, and that after a little while I would have to buy new cylinders. These are soft steel rings. Would you advise me to have these rings removed and new ones put in or let them stay in the car?

Pine Bluff, Ark. E. W. H.

—It has been the experience of many patent ring manufacturers that their rings are apt to cut the cylinders. This is not necessarily true, as in most cases where these rings are applied, they do not cut the cylinders. As a matter of course, any article such as a piston ring is subject to the usage which it is put through by the mechanicians of the garages and in some cases these piston rings are put on without a careful reading of the instructions and contrary to the method in which they are supposed to be applied. The Perfection piston ring as manufactured by the Automobile Construction & Engineering Co., is supposed to be threaded over the piston instead of stretched over it, and if they are put on in this way, they will give good results. Of course if the ring grooves are too wide, and three or four of the patented sections are put in each groove, they will not give the best results and it may be said that neither will any other iron ring or patented device. If the piston rings are stretched in putting them on, they are bent out of shape and will practically never wear in. In that case, there will be more friction and hence more wear than is necessary, but even then, they should not cut the cylinder, and in fact it is stated by piston ring manufacturers that when a cylinder is run dry, it is the piston which will cut the cylinder and not the ring.

The rings can be kept in the cylinders, provided they have never been stretched. If they have not it can readily be noted when the cylinders are off as the rings will be worn evenly all around and where the openings occur at the split, the distance between the ends will be no greater than 3/16 in. If the opening is as much as 5/16-in., ⅜ or more, it is an indication that they have been stretched and should be renewed.

Stalled Motor Hard to Start

Editor THE AUTOMOBILE:—When I stop my engine with the switch I have no trouble in starting it, but when I stall the engine or kill it I have to crank and spin it around a great deal before I can get it started again. What can be the trouble and how can I remedy it?

Westlake, La. P. W. M.

—The fact that your motor acts in the way you describe should not disturb you, but, on the other hand, is an indication that the carbureter is adjusted excellently for the purpose of securing maximum efficiency. You could e change the situation and make the motor easy to start stalling by giving the carbureter an adjustment to pr a richer mixture.

The reason that the motor acts as it does is because you stop the motor on the switch it has chance to r one or two times and thus draw in a fresh charge of gas into the combustion chambers. When the motor is stall killed it is stopped instantly with the result that the remaining in the cylinders is dead and does not posses power to explode. Should the carbureter be so adjusted a much richer mixture would be supplied, the influen the inert gases in the cylinder would be overcome an motor would fire immediately whether it had been st from stalling or for any other reason.

This condition being true shows that the carbureter be adjusted for as fine a mixture as is possible for good ning. It is assumed that the motor acts well while ru since you do not state that any other condition exist however, you notice that the motor is apt to sputter and back when the throttle is opened quickly, it would b to give a slightly richer adjustment on the carbureter. less there is some such indication that the adjustment correct it would be better for you to leave the motor is and exercise care in driving so that you will neve the motor. A driver who is accustomed to his car rar ever, stalls the engine as he knows exactly the amo throttle opening required for each condition and stall the result of not giving sufficient throttle opening f conditions under which the car is being operated.

Alcohol Removes Carbon Deposit

Editor THE AUTOMOBILE:—Is alcohol a good carb mover. If so, how would you use it and how much one use?

Lorain, Ohio. V

—Alcohol is a good carbon remover and for the p can be used in its denatured state which is more eco and just as good. The quantity to use for a cylinder time would be equivalent to five or six tablespoonfuls. the best way of applying it is in a sort of squirt gu posed of a rubber bulb in which there is a long, thin which can be directed against the walls of the com chamber and down on the piston head through a spa opening. This can be readily made by yourself and have such a bend in it that it will be easy to insert opening for the spark plug and at the same time wi shaped that the stream of liquid can be directed agai of the likely spots for carbon.

Carbon deposits are apt to accumulate in pock recesses of the cylinders and also on the piston heads times on motors which have been allowed to go for time without having the carbon removed, it is deposi conical shaped mass on the head of the piston and ve the tip of the cone becomes incandescent and serves

ignite the incoming charge, thus giving rise to the so-called carbon knock. Other places for carbon cones to form are in the top of the combustion chamber and in the recesses above the valve ports. The ports themselves which are swept by the incoming and outgoing gases are most often quite free from any but a soft deposit.

Some people in using denatured alcohol mix it half-and-half with kerosene. The two together form a solvent of the resinous material which acts as a binder for the particles of carbon which in themselves are incapable of cohesion. When this binding material is dissolved, the carbon forms into its natural flakes or scales and can be readily removed. Very often after the carbon has been thoroughly loosened it is necessary to blow out the cylinders so as to remove the carbon flakes and prevent them from again solidifying and becoming a hard carbon deposit. It has been the practice of many to clean one cylinder at a time and then run the motor afterwards with the petcock of the clean cylinder open. This blows out the flakes of carbon which have accumulated, due to the action of the solvent upon the resinous binding material and leaves the cylinder clean.

Another method which has been used successfully in introducing either denatured alcohol or kerosene into the cylinders of a motor for removing the carbon is to feed it into the air intake of the carbureter while the motor is running. The motor will have to be running at quite high speed when this is done, as it will stall as soon as it starts to sputter when the rich kerosene mixture begins to be drawn in.

The time when cleaning a cylinder with alcohol has its best effects is immediately after the motor has come in from a trip and is still warm. At this time a portion of the liquid injected into the cylinders, is vaporized and the vapor of kerosene or denatured alcohol is an effective solvent of the carbon binding material. The best way of carrying through the work would be to lift the hood as soon as the motor comes in from a run and then turn the crank until two of the cylinders are on top center with all valves closed. When this is done these two cylinders should be treated with the liquid which is squirted in through the improvised gun previously described. The motor is then let stand for the night with the alcohol in the combustion chambers of the two cylinders treated. The two remaining cylinders if it is a four, are treated in the same way at the next opportunity.

Some people make a practice of injecting about a teaspoonful of kerosene or denatured alcohol into the priming cup after each trip. When this is done, the necessity for having the carbon removed from the cylinders is postponed for a considerable time as the soft deposit is dissolved each day.

Noise in Gearbox Due to Wear

Editor THE AUTOMOBILE:—Where can I get photographs of all the parts of the Jackson 35 transmission, such as gearbox and shafts? We have a Jackson car which is very noisy in the transmission. Is there any way to get rid of it?

Clyde, Mo. J. E. B.

—You can secure from the Jackson Automobile Co., Jackson, Mich., an instruction book of model 35 Jackson which contains on page 32 a plate showing the complete layout of the gearset assembly. Opposite this on page 33 there is a complete list of parts together with their prices. As THE AUTOMOBILE has no record of any other place to secure a complete layout of photographs of all these parts it would probably be most desirable for you to secure this in the manner described as at the same time the price list will give you the cost of duplicating any parts necessary.

The fact that the gearset is noisy shows that some parts must be worn, probably the gears, as they are the parts of the gearset which are continuously in service and would consequently stand the most chance of becoming worn and noisy. The way possible to proceed is to take the gearbox down and examine all the parts. In ordering the repair parts it is necessary that you give the serial number of the car, which you will find on the small nameplate on the dash.

Inverse Ratio Raises Tooth Pressure

Editor THE AUTOMOBILE:—Will you kindly explain in detail, why and how harm will come by using the motor as a brake on hills? From conversations I have heard held by old engineers and mechanics, they fail to see why harm can come to the gear through inverse ratio as you answered H. H. M.'s inquiry of Johnstown, Pa., in the Rostrum Department of THE AUTOMOBILE for May 13.

Kindly explain this fully and if possible, give problems with illustrations.

Ft. Barry, Cal. A. W. P.

—The practice of using the motor for a brake puts more tooth pressure between the gears than occurs when ordinarily driving the car. If you were to turn by hand a train of gears which instead of having a reduction of 4 to 1 had on the contrary a stepped-up ratio of 1 to 4, you would note the difference in pressure required to turn the gears. It takes exactly the same amount of power applied over the same length of time to bring a car to rest as it does to bring it up to a given speed. That is, the amount of work done is the same. So, it is true to state that if the stop is made in the same distance, the gear wheels are transmitting the same amount of power. Where the factor of increased tooth pressure enters, is, that instead of having a reduction to work

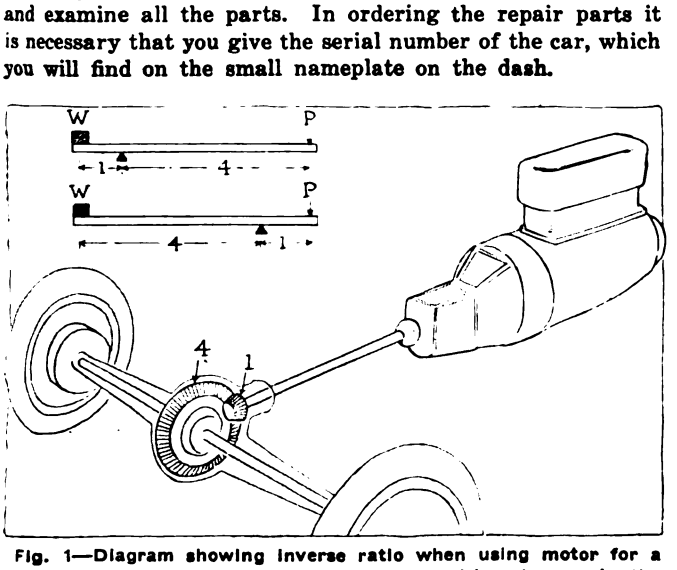


Fig. 1—Diagram showing inverse ratio when using motor for a brake. The small chart shows an analogy with a lever. In the upper example, the pressure on the fulcrum is only 1¼ W, whereas in the lower case where the reduction is 1 to 4, the pressure on the fulcrum is 5 W

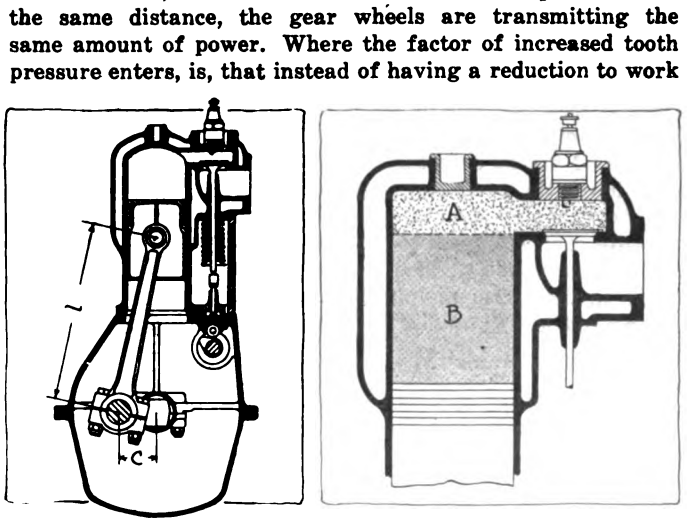

Fig. 2—Diagram showing the determination of the connecting-rod crank ratio and the compression ratio. The left diagram shows the connecting-rod length, 1; and the crank length C. The connecting-rod crank ratio is 1 over C and the diagram to the right A is the compression volume and B the displacement. The compression ratio is A — B ÷ A

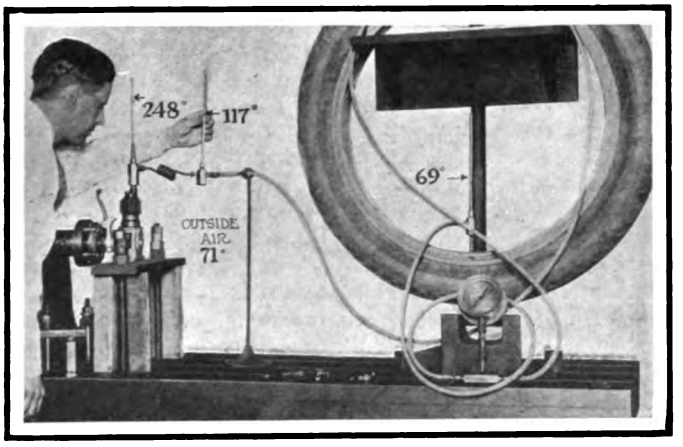

Fig. 3—Illustration showing the arrangement of thermometer used in connection with the test on Stewart tire pump for temperature rise

with of 4 to 1, as in driving a car the ratio becomes 1 to 4 in stopping it. Thus, the proposition becomes similar in many respects to two inclined planes, as shown in the diagram, Fig. 1. If you had to drive a plane which had a slope of 1 to 4 by pressing vertically downwards upon it, it would not move nearly as readily as one which had a slope of from 4 to 1, and, while this analogy is not accurate, it expresses the condition which occurs when the teeth of the small bevel gear sustain the pressure that they do when the drive comes through them in an inverse direction. With a worm and gear this analogy is quite accurate.

Determining Angle of V-Motors

Editor THE AUTOMOBILE—1—Why do they make eight-cylinder engines of the V type 90 deg. apart and twelve-cylinders 60 deg.?

2—How does the Delco motor generator operate?

3—What is meant by connecting-rod to crank ratio?

4—How do you figure compression ratio?

H. W. C.

Albany, N. Y.

—In the eight-cylinder motor there are four explosions to each revolution; dividing 360 deg., or a complete revolution, by four gives 90 deg., the necessary angle between the cylinder blocks. With a twelve-cylinder motor, there are six explosions to a revolution, and dividing 360 by six, gives 60 deg. as the necessary angle.

2—The motor generator is so wound that when being driven by the motor it acts as a generator and when receiving current from the battery, it acts as a motor. With the battery charged and the switch closed, current flows through the windings of the motor generator, causing the armature to rotate and act as an electric motor. When the gasoline engine drives the generator it gives out current which is utilized for charging the storage battery.

3—By connecting-rod to crank-ratio is meant the length of the connecting-rod divided by the length of the crank. As shown in the accompanying diagram, Fig. 2, if L is the connecting-rod length, and C the length of the crank, the connecting-rod to crank ratio R equals $\frac{L}{C}$.

4—Compression ratio is the ration between the entire volume of the cylinder and the volume of the compression chamber. In other words, it is the piston displacement plus the compression volume, divided by the compression volume.

Three Thermometers on Stewart Test

Editor THE AUTOMOBILE:—I notice in your issue of Aug. 12, on page 303, that you mention a test on a Stewart tire pump which brings out the fact that the air entering the tire at a line pressure of 101 lb. is 69 deg. or 2 deg. cooler than that of the atmosphere. Will you kindly tell me how th thermometers were mounted to secure the tabulated result in both the power tire pump and the foot pump?

New York City. S. E. J.

—The tests you mention were made by inflating a 37 by in. tire. In place of the regular air pressure gage on th hose connection, a large dial Bourdon gage was inserted, s as to give the most accurate reading of the pressure. Th temperature of the air was taken at three points simultane ously, as shown in Fig. 3. One thermometer was placed i the air passage where the air left the tire pump *A*. Anothe thermometer was placed between the cooling coil in th Stewart tire pump and the beginning of the hose connectio at *B* and the third thermometer was placed at the tire valv where the air enters the tire at *C*.

The arrangements made for holding the tire and measu ing the pressure with the foot pump are shown in Fig. 5.

Waterjackets on Speedwell-Mead Motors

Editor THE AUTOMOBILE:—I note in your issue of Aug. on page 285 questions regarding the jacketing of the Mea rotary valve motor in the Speedwell cars. Would you kind inform me if the jacket spaces as shown by the illustratio on page 285 are in proportion?

New York City. B. H. S.

—The waterjacket spaces as shown in the diagram a about proportional. The diagram having been made fro actual sections of the cylinders. For your benefit, howev Fig. 4 shows engravings made from photographs of cu away cylinder blocks.

Probable Break in Fine Winding

Editor THE AUTOMOBILE:—I have a 1913 Cadillac, a cannot start the car or run the engine on the battery ignitio I have checked over all connections and tested the wiring, of which seems to be O. K. I have also changed the batte connections on the induction coil to the coil of the generat but without success.

The battery button on the switch has the same effect the relay as the starting button, but a much weaker vibrat is had. As I am starting and running on the generator present, I have no trouble, but would appreciate what s gestions you may have to offer in this regard.

Minneapolis, Minn. G. P. C

—From what you say it would seem that the difficulty only on the battery side and the nature of the trouble is s that although you are unable to run on the battery ignit the shower spark is still obtained by pressing the but marked B.

It would seem that this difficulty is in the ignition re which is equipped with two windings—one a course winc and the other a fine winding. The fine winding is so nected around the contact points of the ignition relay, whenever the circuit through it is closed, the current flow through it is sufficient to magnetize the core of the relay to enable the little armature at the top of the relay to be down against the pole piece of the magnet until the cir is opened by the breaker and distributer. The coarse wind above mentioned on this relay are connected in series with dry cells and the contact point of the relay and the spar obtained by breaking the circuit through the coarse winc

When, therefore, the circuit through the fine windin closed, only a single spark is obtained at the spark plug the reason that when this circuit is closed at the bre points in this distributer, the armature on the little rel drawn down, opening the points on the relay which ar series with the coarse winding, thus breaking the ci through the coarse winding and giving a single spark a plugs.

Inasmuch, however, as the fine winding is also closed little armature is unable to go back to its original po

and close the contact points. It is therefore compelled to remain down until the circuit is opened through the distributer. When, however, the starting button on the switch is depressed, the circuit through the fine winding on this little relay is opened. Under these conditions, therefore, when the corcuit through the coarse winding is closed through the breaker points in the distributer, the little armature at the top of the relay is drawn down in the usual way, breaking the circuit through the coarse winding at the relay contacts. The minute these contacts at the relay are broken the magnetisim in the coil dies away; the relay returns to its original position, the contacts are again closed; the pole piece again magnetized and the relay again drawn down, breaking the circuit again through the coarse winding at the relay point. As the fine winding is open there is no means of holding the little armature down firmly against the pole piece. Hence it vibrates very rapidly, making and breaking the circuit through the coarse winding at a very high rate, thus giving a shower of sparks at the spark plug.

From the information you give, it would seem that there is either an opening in the fine winding or that the relay is improperly adjusted. There are two windings upon the magnet, one being comparatively coarse and the other fine, as described. To quote from the Cadillac instruction book covering this point, these wires are so connected that the current ceases to flow through the coarse wire when the contact is broken. The fine wire connected around the contact is so arranged as to hold the armature after the current is broken through the coarse wire coil. If this second coil were not affected the contacts would vibrate giving a shower of sparks at the plug instead of a single spark. This is what is done in starting and it is done at this time only because it would be wasteful of current to continue it under running conditions.

If the armature vibrates rapidly when the *B* button on the ignition switch is depressed, the holding coil circuit is open. Test the circuit and in emergency connect the two terminals closest together on the relay with a wire. This will stop trouble if the break is outside the relay. If the armature vibrates freely, it indicates either weak batteries or dirt between either the relay or timer contact.

Again quoting from the instruction book covering this point, the following suggestions are made:

"Loose connections, grounded wire and weak batteries may cause improper working of the relay through no fault of the device itself. The only point of adjustment in the relay is at the pole piece. This regulates the distance between the armature and the magnet pole and a gap between the contacts. Adjustment is made by turning the notched head clockwise as one looks down upon it to increase the gap between contacts and vice versa. Normally this adjustment should be such that the distance between contacts when armature is pressed down is about equal to the thickness of a sheet of paper. A simple way in which this adjustment may be made is to turn the notched head of the adjusting screw in a counterclockwise direction until the motor stops firing. Then turn it four or five notches in the opposite direction. Under no condition should the adjusting screw be turned very far in either direction. If particles of dirt get between the armature and pole piece at the point they may be removed by slipping a piece of smooth paper between the parts mentioned, pressing down slightly upon the armature and pulling out the paper."

It is therefore suggested that you make sure that this fine winding in the relay is not open; that the relay itself is correctly adjusted; that all the dirt is removed; that the contact points are in good condition, that all connections are tight and that the dry cells themselves have not become too weak and need replacing. The wiring diagrams of this car are given fully in the Cadillac 1913 instruction book which was provided with the car.

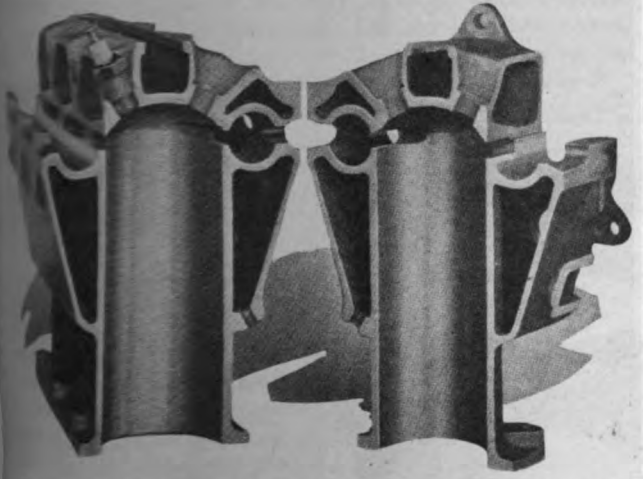

Fig. 4—Arrangement of cored passages on the Speedwell Meade motors which were described in the Rostrum issue of THE AUTOMOBILE for Aug. 12.

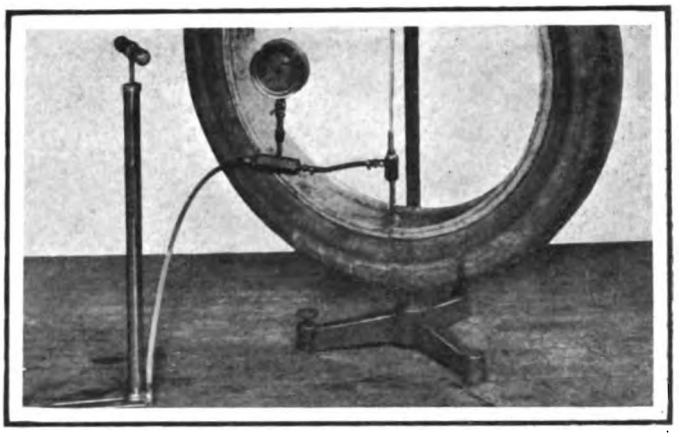

Fig. 5.—Position of thermometer and pressure gage used in connection with tests showing temperature rise with ordinary foot tire pump

Simplex Won Three Successive Races

Editor THE AUTOMOBILE:—Did the Simplex win three 24-hr. road races in succession?

Why is the Simplex not being entered in the 500-mile races now prevailing?

Did the Simplex ever make 100 m.p.h. according to record?

R. L. R.

New Haven, Conn.

—The Simplex 50-hp. stock chassis won the 24-hr. races at Brighton Beach in 1909, 1910 and 1911. These were three races in succession.

2—The Simplex is not being entered in 500-mile races because the Simplex company is not a manufacturer of special racing cars and the 50-hp. motor made by this concern has a cubic inch displacement of 597. As the limit for cubic inch displacement in these races is now 300 it is impossible to enter the cars in the races.

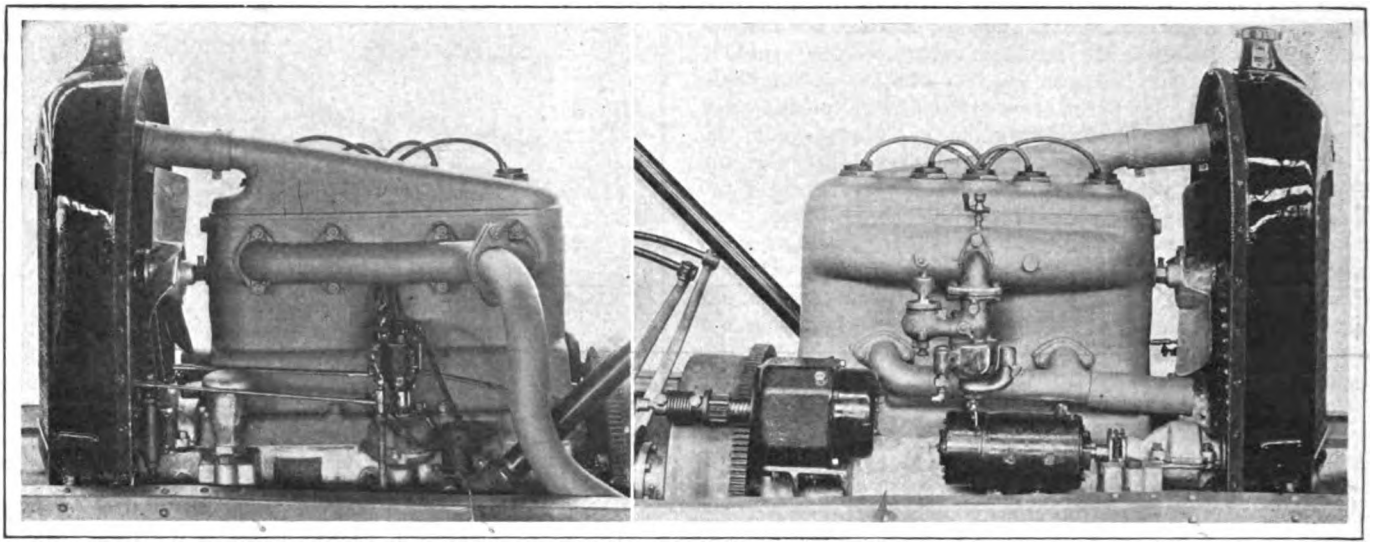
3—The Simplex car has made 100 m.p.h. according to several records.

Compression Pressure Is 70 Pounds

Editor THE AUTOMOBILE:—I have a 1912 four-cylinder, Isotta-Fraschini, the bore being 3⅞-in. and the stroke 5½-in. It is the O. M. type of car No. 1616. What compression should the motor have? Who has the agency for this car?

Wilmerding, Pa. D. G.

—The compression pressure of this motor should be about 70 lb. per sq. in. The agency for this car is the Isotta-Fraschini Motor Co., New York City.



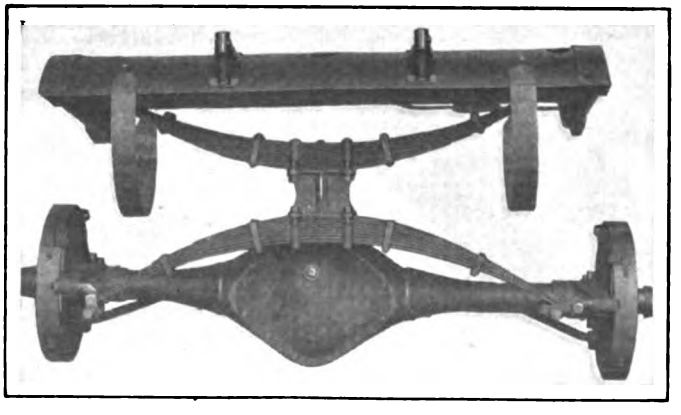
Both sides of the Moline-Knight 40 motor showing how block casting and cored passages have resulted in clean exterior

Moline-Knight Featured By Simplicity

Model 40 at $1,475 Has Cored Manifolds, Block Casting, Central Spark Plugs and Many New Chassis Features Including Novel Type of Rear Suspension

PRACTICALLY all the features which were successfully used in the Moline-Knight 50 motor have been retained in the new one, which is listed under the name of model 40, at $1,475, but in addition a number of unusual features which have all tended toward simplified design have been introduced. The intake manifold is integral with the cylinder block, the object being to have it surrounded by a complete waterjacket space to insure the vaporization of the heavy gasoline now on the market. The cylinder heads are covered by a removable plate over the cylinders providing a greater amount of waterjacketing space over the top of the cylinders than is generally employed. The motor has aluminum alloy pistons, the electric wiring is brought up through the block casting from the distributer to the spark plugs and in addition incorporates a valuable detail improvement in the drive of the fan and the manner in which it is adjusted.

The results obtained by the new motor are shown in the brake horsepower curve herewith. It will be noted that the peak of the curve is at approximately 2200 r.p.m. and the curve is practically a straight line from 700 to 1350 r.p.m., at which point 34 hp. is developed. The port areas of the motor which have helped toward securing the power curve shown are 1.42 sq. in. for the intake and 1.62 in. for the exhaust. The valve timing shows the characteristics of a high-speed motor, the exhaust opening 50 deg. before lower center and closing 11 deg. past upper center. The intake opens at 18 deg. past upper center and closes at 50 deg. past lower center. The throw of the eccentric for the sleeve is 1 in.



New rear suspension adopted by the Moline company

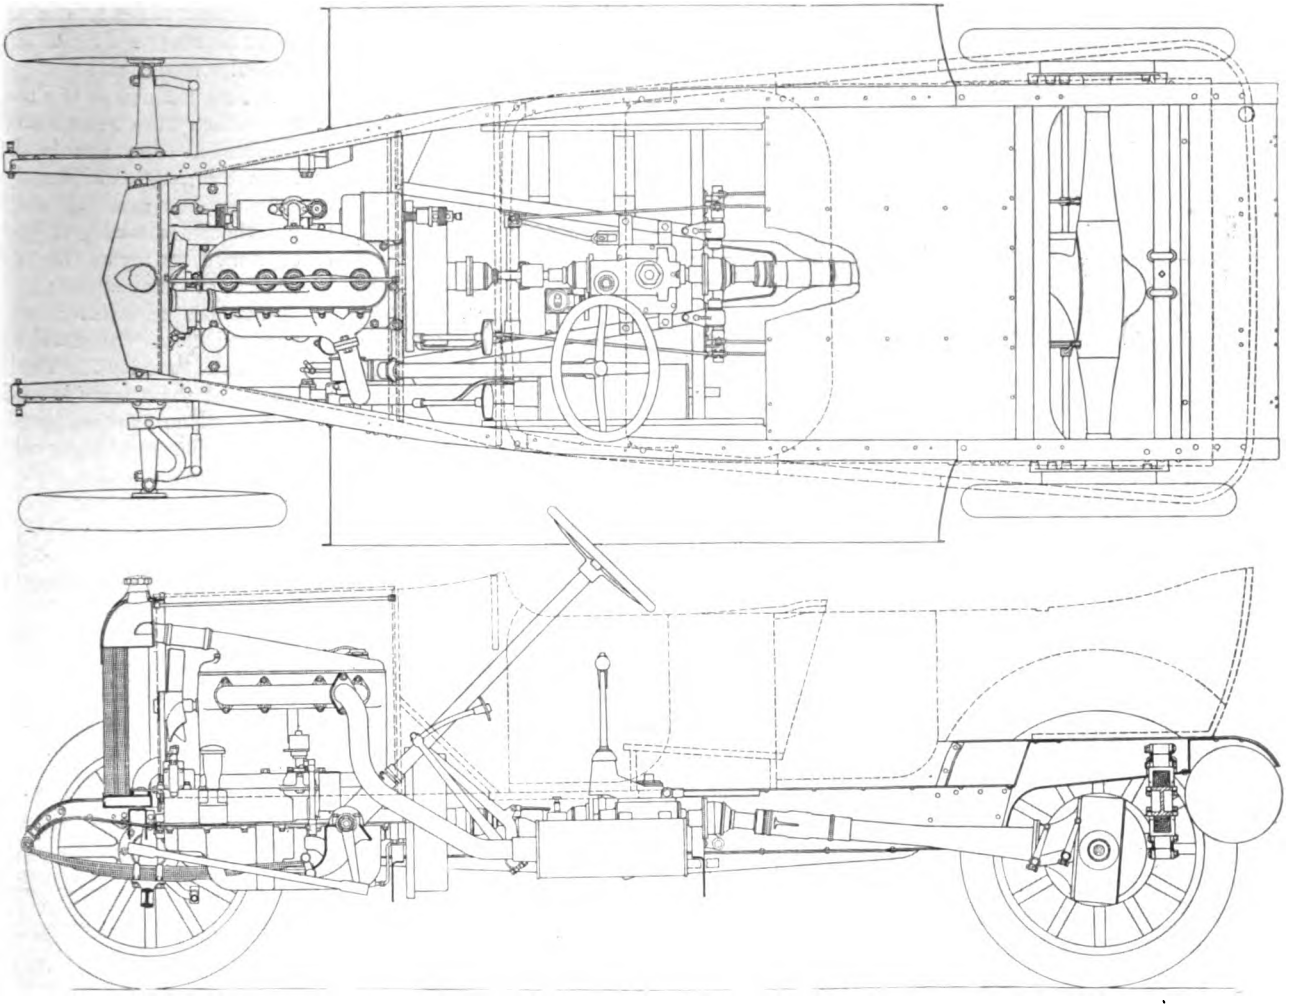
Referring to the sectional view of the motor, it will be noted that the head of the cylinder is a cone-shaped cap carrying the spark plug in its center. This sets into the cylinder to a depth of several inches. An example of the care with which the water system has been designed on this car is shown here, the space between the center and sides of the cap being in the water circuit so that the upper ends of the two reciprocating sleeves have water circulation on both sides of them at A and B. The cylinder cover plate forms the upper water manifold through which the water passes to the radiator. The lower connection from the radiator to the motor has two branches, one leading to the forward and the other to the rear end of the cylinder block, thus insuring uniform distribution.

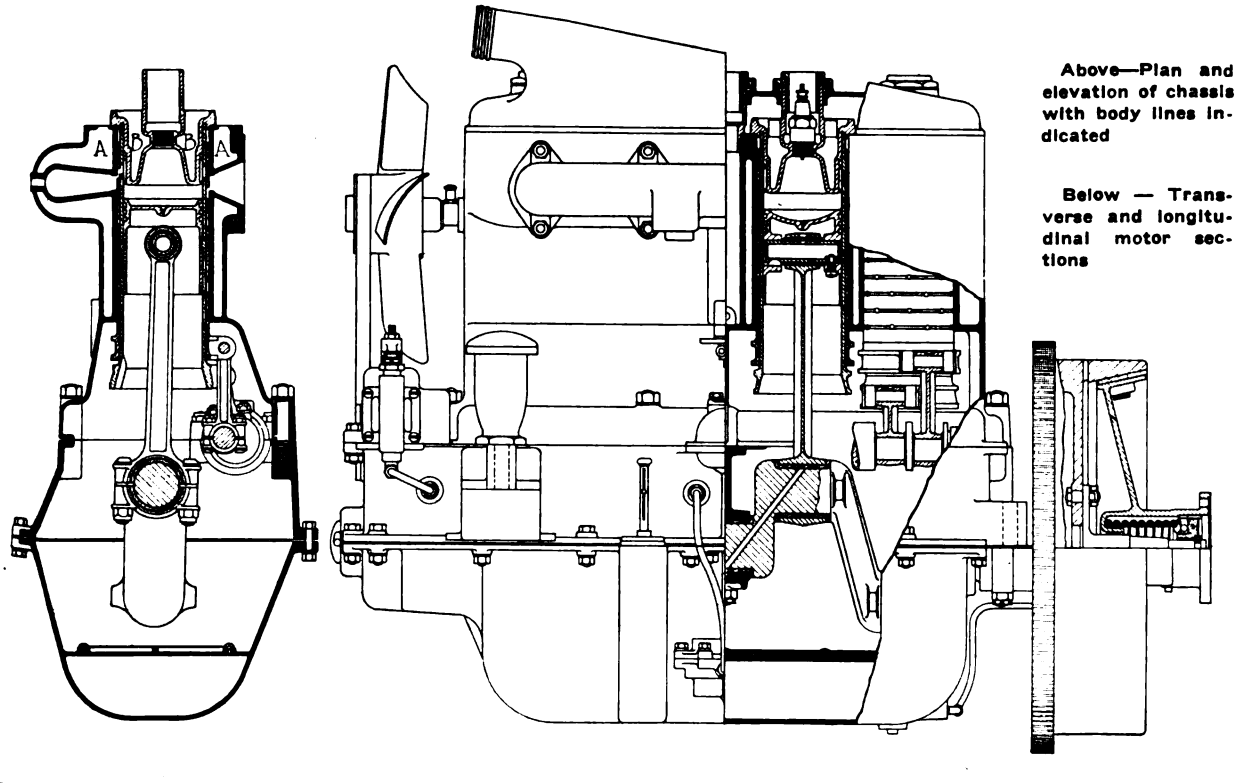
Briefly, the new car has a 3½ by 5 four-cylinder block Knight motor, two-unit electric lighting and start system, thermo-syphon cooling, 118-inch wheelbase, cone clutch, three-speed gearbox with center control, spiral bevel drive and 34 by 4-inch tires.

A change is in the use of an I-beam connecting-rod in place of the tubular section used on the 50. The oiling system has been redesigned in some details and in connection with this the vertical shaft which drives the oil pump carries, at its upper extremity, the distributer for the Connecticut ignition system.

Other than in the use of aluminum pistons which were used in the 50, nothing radical has been done in the way of material. The cylinders are a dense gray casting iron and the cylinder heads also

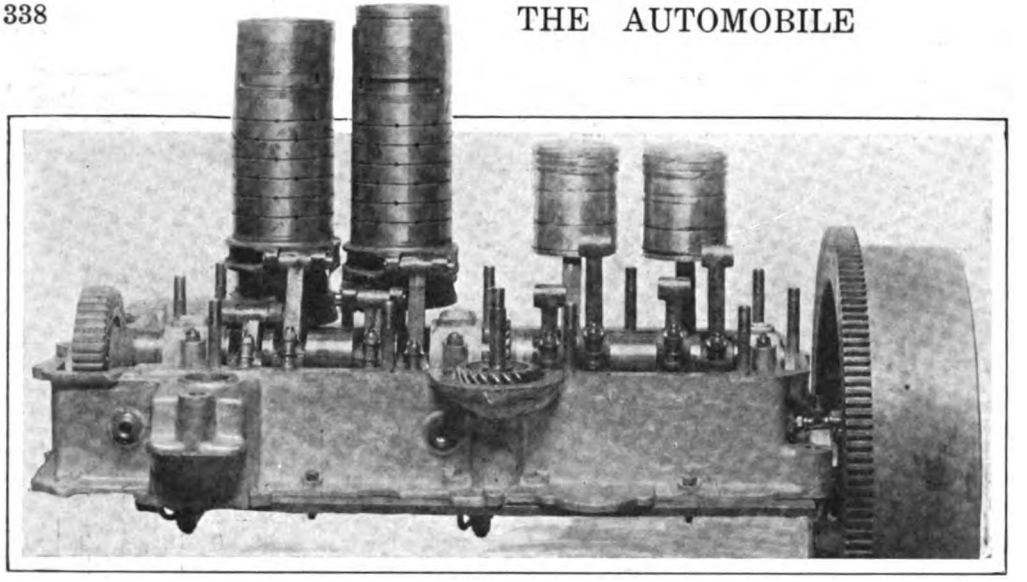
Constructional Views of the Moline-Knight 40





Above—Plan and elevation of chassis with body lines indicated

Below — Transverse and longitudinal motor sections



Motor cylinder block removed showing sleeves and crankshaft units

a gray iron mixture. The sleeves are also cast iron and machined within limits to render the sleeves interchangeable. The wristpins are tubular and case-hardened, transmitting the drive to the drop-forged double-heat-treated connecting rods. The crankshafts are also drop-forged of 0.50 carbon steel and go through two heat treatments.

Eccentric Shaft Drive by Silent Chain

The eccentric shaft is driven from the crankshaft by a silent chain, the centers on this drive being kept very short. In order to keep a proper tension on the chain and proper valve timing the sprocket on the eccentric shaft is provided with a Vernier adjustment. The material used in the eccentric shaft is open-hearth 0.50 carbon steel. The running compression of the motor is 75 lb. per sq. in.

In dimensions the motor shows no departures from ordinary practice, the connecting-rods being 10¾ in. in length with 2½-in. bearings at the big end. The diameter of the crankshaft is 2 in. and the piston length is 1.21 times the bore or 4¼ in. The bearings are bronze-backed nickel-babbitt. The clearance allowed between the sleeves and between the sleeves and cylinder varies between 0.001 and 0.0015 in. There are three piston rings 3/16 in. in width and they are all of the eccentric type.

Pressure Lubrication System

The pressure system of lubrication is used. A gear pump driven from the eccentric by means of a spiral gear takes oil from the oil sump in the lower half of the crankcase and pumps it into a supply pipe running the entire length of the case. From this point leads are taken to each of the three main bearings. Oil is carried to the crankpin bearings through leads drilled in the crankshaft arms. These holes are drilled from the crankpins to the main bearings and register at each revolution with the oil leads to the main bearings. The oil pressure is controlled by means of an oil by-pass valve connected directly to the throttle thus opening or closing the throttle which automatically increases or decreases the oil pressure to the bearings. The oil pressure varies from idling to full open throttle from 5 to 40 lb. The sleeves and pistons are oiled from the spray of oil from the connecting-rod and the oil by-pass is so placed that the surplus oil not needed for the lubrication of the motor flows to the eccentric shaft and generator chains. The oil draining from all parts is filtered through a fine gauze over the oil sump, removing all particles of carbon and residue coming from the motor, or any foreign substances that might be in the oil before it is returned to the oil sump.

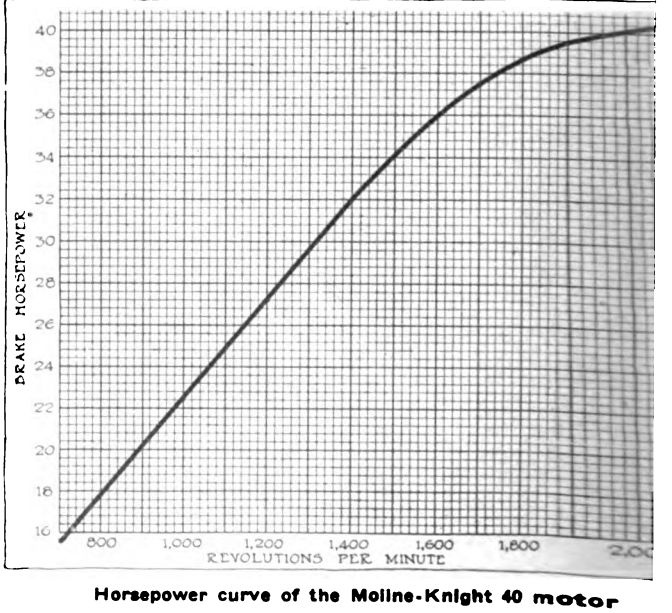
The electric system of the car consists of a Connecticut ignition outfit with a Wagner generator and an Auto-Lite starting motor. The gasolin feed is by the vacuum systen with the gasoline tank on th rear of the chassis where it i accessible behind the body The carbureter used is th Schebler model R.

A new feature is the metho by which the fan belt i tightened. The fan is drive from the generator shaft by split sheave and if the fa belt becomes loose, it can b tightened by tightening a nu ahead of the sheave. Th brings the two halves of th sheave closer together ar tightens the belt. The nu ahead of the sheave is secur in any given position by a st lock washer and when the a justment is made can be secured by attaching this.

The clutch used in connection with the new car is a co ventional leather-faced cone design with cork inserts. T clutch is aluminum and is connected with the gearbox two universal joints. The gearbox is located amidships. T gearset is a compact design mounted on annular ball bea ings and plain bearings with the shifter lever centered rectly on the cover plate. The gears are 3.5 per cent nic steel and the distance between the bearings on the ma shaft of the gearset is 5½ in. The face width of the ge is 0.625 in.

Inclosed Propeller Shaft

The drive is taken through a high-carbon steel shaft 1.3 in. in diameter to the spiral-bevel rear axle which is hou within a pressed steel cover. A seamless tube is used house the propeller shaft and is bolted to the differential c rier. The propeller housing is kept in alignment by st rods and the axle housing is practically relieved of stra as with the new spring suspension the support is brou closer to the wheels than is generally the case. The driv spiral bevel gears are of nickel steel and the axle shafts also nickel steel 1¼ in. in diameter. The driving pinion is ried by a double row bearing behind the pinion and a si row bearing ahead of the pinion, thus assuring perfect m ing of the spiral bevel gears. All the other bearings in axle have Hyatt rollers. The assembly of this part of

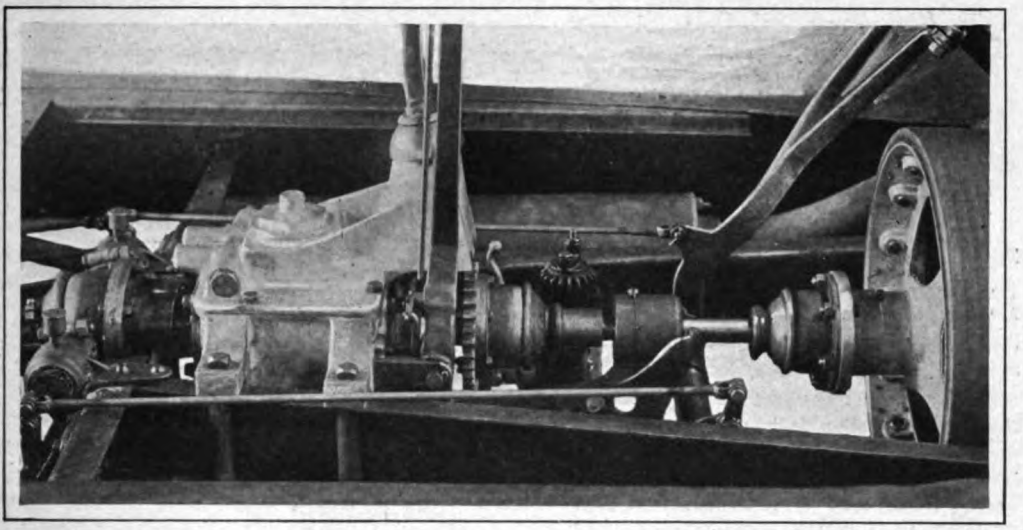


Horsepower curve of the Moline-Knight 40 motor

car is very simple as the axle shaft can be removed on removing a collar and then the pinion and differential assembly can be disassembled.

Double Cross Spring

Perhaps the most radical change about the entire car is in the spring suspension. As shown by the accompanying illustration, the spring is comprised of two independent cross members, which is entirely unconventional. The assembly is made up of two semi-elliptic springs, 42 in. in length, bolted together in the center by means of a special fitting and clips. This makes a double semi-elliptic cross-member running parallel with the rear axle. One end of the upper spring shackles to the frame while the other is attached to the frame but is stationary. The lower spring is fastened in the same manner except that the shackles are on the brake drum. It is stated that one of the results of this spring suspension is to avoid side sway. It is also claimed to be lighter than the conventional method of suspension.



Clutch, gearset and universal driving members in the Moline-Knight model 40

Another development is in the frame construction which has side members 7 in. in depth. The rear part of the frame is stiffened by a pressed steel brace which is formed to go over the gasoline tank and besides being a stiffening member is also a protection to the tank. Another member which absorbs wracking strains is the tonneau floor which is composed of a sheet of pressed steel. Additional strength is gained by the subframe on which the gearset is suspended. The running board suspension is not riveted to the frame in the usual manner by brackets, but instead, the running board itself is hot-riveted directly to the frame. The two ends of the running board curve upward and bolt firmly to the fenders giving a complete frame assembly of great strength, due to its unit construction.

Wire Wheels $80 Extra

Two sets of brakes are on the rear wheels. They have 14-in. drums with face widths of 2½ in. The wheel equipment consists of four wood wheels and an extra rim with wire wheels optional for $80 per set. The fenders are crowned and the finish consists of twenty coats of paint and varnish. The body is a sectional design made in three units, consisting of the cowl, front seats and tonneau. This is done to guard against squeaking and also if desired, the tonneau can be removed and an open body substituted for transporting merchandise.

French Car Owners Must Pay Taxes

PARIS, Aug. 7—French automobile owners are eligible for the payment of all motor taxes, notwithstanding the war. In the whole of France there are restrictions on motoring; in many districts it is forbidden to use a car; in the parts of France farthest removed from the battle zone it is necessary to have a pass renewable fortnightly. Hundreds of cars are lying idle owing to the absence of their owners at the war. In all these cases taxes have to be paid. The claim has been put forward that where permission to use a car cannot be granted, or where the absence of the owner has made the use of the car impossible, taxes should not be exacted. This claim, however, is not admitted. Ownership of the car entails taxation. As the average automobile tax in France is $30 to $35, the matter is of some importance to car owners.

Same Situation in Switzerland

The same situation has arisen in Switzerland, where for the last 5 months of 1914 private automobile traffic was forbidden. In the canton of Geneva five-twelfths of the taxes have been remitted, thus owners do not pay for the period during which they were not allowed to use their cars. In other cantons the taxes are maintained for various reasons. In several cases the tax is so low, being about $4 a year, that the authorities consider it is not necessary to make a reduction. In other cases it is stated that the circumstances are exceptional and automobile owners must take their share of supporting the State. When automobiles are requisitioned temporarily for military service they are not taxed during that period. In France, if automobiles are taken into the army for a limited period and then returned to their original owners, they are taxed as usual. Thus, no matter what his military status, the car owner must pay for the privilege.

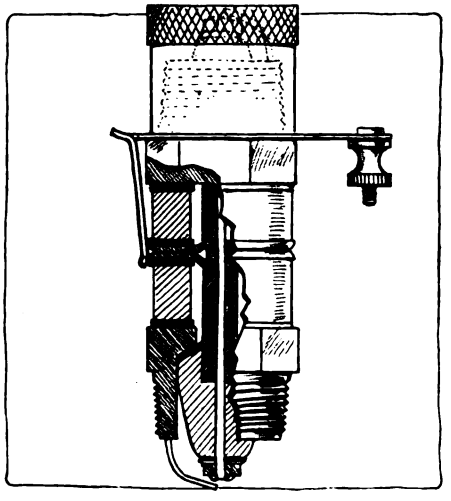
A Three-Passenger Lexington-Howard

Novel body recently brought out by the Lexington-Howard Co., Connorsville, Ind.

ACCESSORIES

Double-End Spark Plug

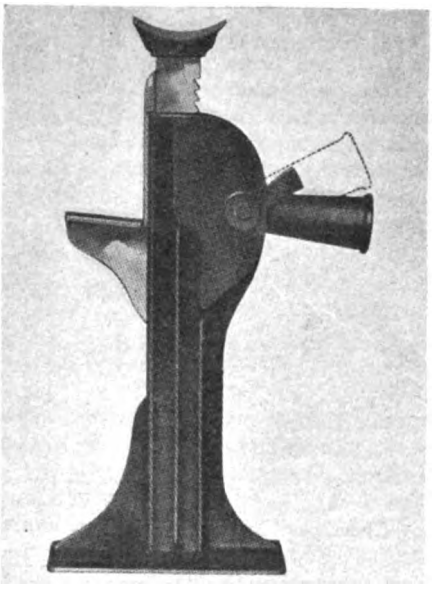
BOTH ends of the Double End spark plug are alike in construction so that either may be inserted in the cylinder. When in use, the upper end fires as well as that in the cylinder so that it acts as an indicator of the condition of the spark for the cylinder. It is practically two plugs assembled into one, as illustrated. The insulator is sheet mica, and when the points at one end are worn out, the plug may be reversed after the worn part is cut out of the circuit. The plugs are listed at $1.50 each.—Twin-Spark Sales Co., New York City.



Either end of the Double-End spark plug may be used

Limousine Jiffy Jack

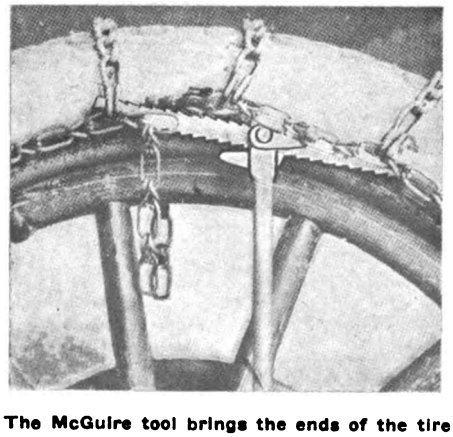
The latest model Jiffy jack is the limousine type illustrated herewith which is claimed to have a lifting capacity of 5000 lb. It is of the rack type, the rack being made of laminated steel, the pawls are forged with machined tips, heat-treated; pawl controlling parts are of case-hardened machine steel, and the pawl spring is of rust-proofed steel. When the load is removed the rack automatically drops. The jack weighs 9 lb. Furnished with wood handle it sells for $3.50—The Jiffy Jack Co., Cleveland, Ohio.



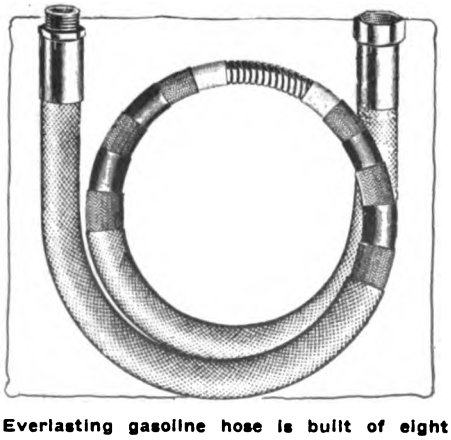
Limousine model Jiffy jack with safety drop

McGuire Tire Chain Tool

To assist in applying tire chains easily and securely, the McGuire tool has been brought out, allowing the chain ends to be brought together easily. The tool uses a dog and a ratchet, the dog holding the ratchet in any desired position. Hooks on the ratchet grip the chain ends and by pushing down the handle the ends are brought together as far as desired, the ratchet automatically locking itself in position, holding the chain ready for closing of the clamps. The tool is 9 in. long, weighs 14 oz. and can be disassembled and put in the chain bag. Price, $1.—E. P. McGuire, Van Houten, N. M.



The McGuire tool brings the ends of the tire chain together easily



Everlasting gasoline hose is built of eight layers, no rubber is used

Chicago Flexible Tubing

The Everlasting gasoline hose is built up of eight layers, the inner lining being of flexible steel under a layer of fiber, one of braid, one of special gasoline-resisting composition, these two layers then being repeated and then the waterproof outer jacket which is woven on. No rubber is used. Other products of the maker of Everlasting hose are hot air hose for carbureter connections, oil, air and steam tubing and acetylene tubing and connectors.—Chicago Tubing & Braiding Co., Chicago, Ill.

Apco Anti-Rattlers

A combination hood anti-rattler and holder is one of the many Auto Parts products. This is a helical spring which has several special clamps attached. The spring is placed transversely under the hood and the clamps are slipped over the lower edges of the hood. The sides of the hood may then be raised to any extent desired without rattling. This arrangement is of assistance in keeping the motor cool in very hot weather as a circulation of air may be obtained without the disagreeable clatter of the hood rattle. The anti-rattler is finished in black enamel and sells for 10 cents.

Another Auto Parts product is the new door anti-rattler for Fords which is a simple construction of spring steel, which is attached to the body part of the hinge by one of the original wood screws. It is made for the 1913, 1914 and 1915 Ford models. It is finished in black enamel and sells for 20 cents. It is supplied to the trade on a display stand, there being twenty anti-rattlers to the stand.

The new Apco valve grinding tool has a universal joint which compensates for any variation from vertical when in use. The weight of the device is sufficient to provide the necessary pressure. It sells for 20 cents.

An improved cutout pedal is also offered which is attached by locking nuts and washers instead of screws.—Auto Parts Co., Providence, R. I.

Strickler Grease Gun

A grease gun designed to force grease through obstructed places with heavy pressure is the Strickler, which is of heavy construction throughout, the hexagonal steel barrel being threaded for a plunger, also of steel, with an air chamber, as the accompanying illustration shows. The outer end of the plunger has a hexagon head to which a wrench can be applied and a hole for a bar. The lower

end of the barrel is threaded for nozzles which, in turn, are threaded to go into grease cup tapped holes; nozzles are made in all standard sizes, with both internal and external threads.

In using the gun the nozzle is screwed into the place of the grease cup and the plunger screwed down by hand until the grease is forced through the bearing. If grease cannot be forced through in this way pressure is applied with a bar or wrench and the bearing moved at the same time to facilitate the passage of grease. The maker states that a pressure of 900 lb. can be attained. Price, $3.50.—Powers Sales Co., Chicago, Ill.

Lawall Vulcanizer

The Lawall vulcanizer is of the tool-box type and can be used for both tube and casing work. An important feature of the device, which is of the type in which gasoline in a reservoir is ignited and allowed to burn out, is that the fuel container has a deep and a shallow section; the fuel in the shallow section burns for about 5 min., this being the time required to bring the vulcanizer to the proper heat; by that time the fuel has run dry in the shallow part and the deeper section, nearer the mouth, burns out, being just sufficient to maintain the proper temperature for 15 min. Part of the outfit is a swivel clamp by means of which the vulcanizer can be held against the tire for casing work or on a tube for patching. The complete outfit consists of the vulcanizer proper, made of aluminum, a swivel clamp with small patch clamp, tube plate, repair material and scissors. Everything goes into a neat canvas roll. Price, $3.50.—L. C. Lawall, Richmond, Ind.

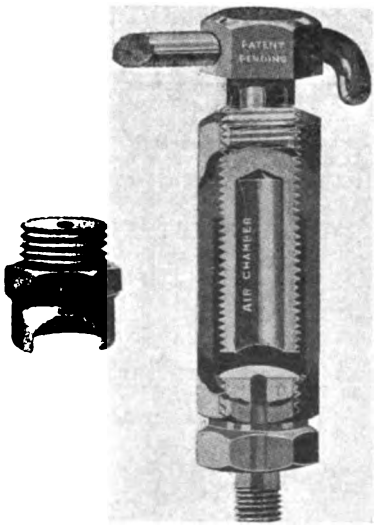
Foxy Gasoline Gage

The Foxy gasoline gage for Ford cars has been designed to meet the requirements for a device which can be easily installed. It consists of a cylindrical float chamber on top of which is mounted a glass gage tube, the pointer of which is a little ball mounted on the vertical rod extending upward from the float. Figures form the indicator on the gage tube.

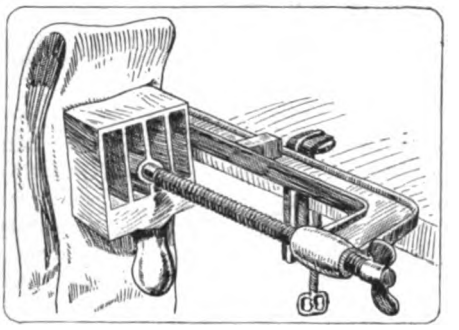
To install the device, the gage is secured to the dashboard and then connected in the gasoline feed pipe by means of a T fitting, a notch being cut in the dashboard for the gage to fit. The device sells for $3.50.—Fox Gauge & Specialty Co., Brooklyn, N. Y.

Paco Racing Bodies

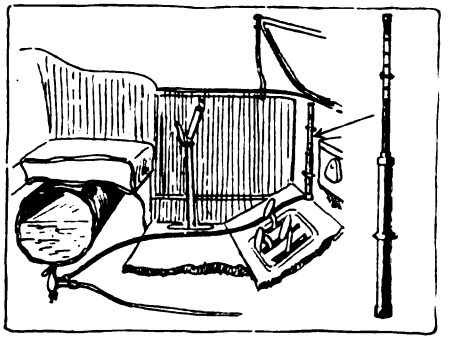
For owners of Ford and other small cars who wish to make their cars into speed creations the Paco racing type bodies have been designed. These are in two streamline styles, one for track work and the other for ordinary use, the former having its seats staggered and



The Strickler grease gun forces the lubricant through obstructed places with heavy pressure



The Lawall tool-box-type vulcanizer can be used for both tube and casing work



The Foxy gasoline gage is mounted on the Ford dash and connected directly to the tank

the cowl brought up close to the steering wheel with the exhaust pipes coming through the hood to meet in a single large manifold. The rear is streamlined and the steering column raked while the pedals are bent to conform with the low driving seat. Equipment includes a new dash, hood air pump and pressure feed system with complete directions for installing. The material is 20-gage iron, with all seams riveted.

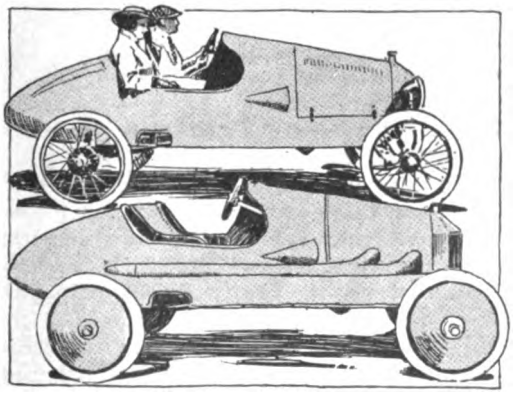
The other body is similar in general appearance but the exhaust pipes are not brought through the hood. Equipment is the same. The bullet-shaped rear contains a 15-gal. gasoline tank and sufficient space to carry luggage. Crated for shipment, either body weighs about 350 lb. Price of either style is $165 complete.—Peoria Accessory Co., Peoria, Ill.

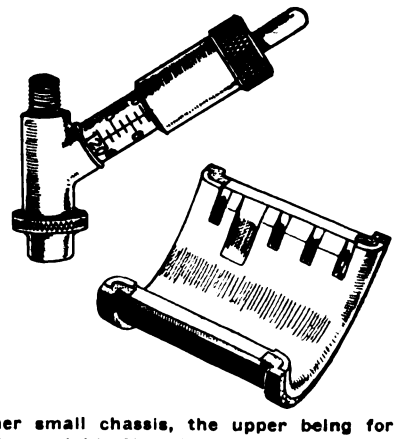
Nurinkle Tire Gage

Under the name of the Nurinkle, an automatic tire gage has been put on the market. With this gage in the air line and adjusted to a certain pressure, the moment this pressure is attained the excess air is expelled through a check valve. At the same time the gage registers the pressure on a graduated cylinder which is part of the device, as illustrated herewith. The small knurled nut on the top of the device serves to regulate the pressure. Price $1.25.—Nurinkle Co., Indianapolis, Ind.

Victor Bronze-Back Bearing

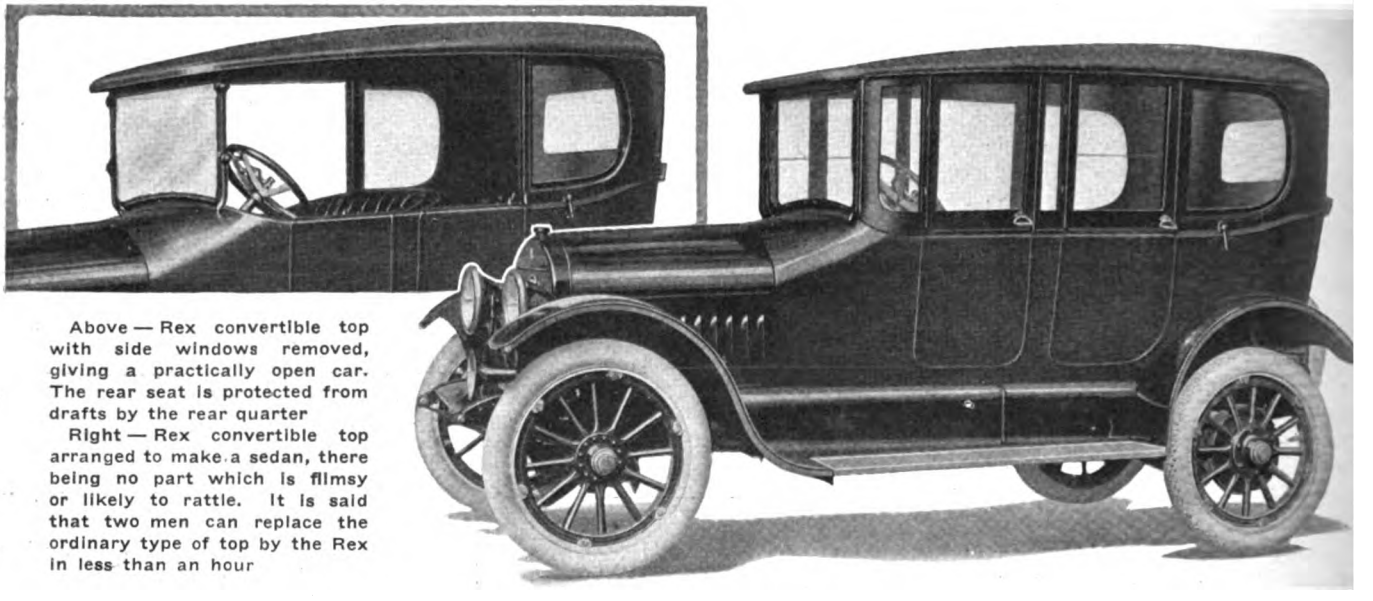
Victor is the name of a bronze-back die-cast bearing in which the soft metal is made almost integral with the bronze by an ingenious locking arrangement. The bronze shell is machined to size, after which the bearing metal is die cast in the shell under pressure and is soldered and locked as indicated in the accompanying illustration by the dovetail joints formed between the bronze and bearing metal. These joints are said to hold the bearing metal to the bronze at the four sides so strongly that separation is practically impossible.—Modern Die & Tool Co., Indianapolis, Ind.





Left—Paco racing type bodies for Fords and other small chassis, the upper being for ordinary work while the lower is for track racing. Upper right—Nurinkle tire gage. Lower right—Victor bronze-back bearing

Rex Convertible Top—Sedan or Open Car



Above — Rex convertible top with side windows removed, giving a practically open car. The rear seat is protected from drafts by the rear quarter

Right — Rex convertible top arranged to make a sedan, there being no part which is flimsy or likely to rattle. It is said that two men can replace the ordinary type of top by the Rex in less than an hour

THE large number of convertible bodies which have been introduced during the past 12 months shows that there is a strong tendency to replace the ordinary top by something which gives a better combination of the advantages of closed or open bodywork. One of the latest attempts to solve the problem is the Rex sedan top made by the Rex Buggy Co., Connersville, Ind., and this has been taken up by the King Motor Car Co., Detroit, Mich.

To accommodate this top the body is made to an ordinary open design, and top irons are attached at the usual places, but instead of using the ordinary iron a socket is fixed securely to the main body frame, showing a threaded hole starting flush with the face of the panel when the body is completed. There are four of these sockets and the irons for carrying the ordinary folding top simply screw into the sockets.

To fix the Rex top the ordinary irons are unscrewed and four others put in their place; these providing four vertical studs on which the Rex top is set and held down by nuts. This gives a rigid attachment for the rear part, and the front end is secured to the upper extremities of the windshield irons.

The main frame of the Rex is hard wood, well strengthened at the joints and comprises the leather and Pantasote roof with the back piece and a post located just aft of the tonneau doors on each side. In this condition the body is just as much an open one as with an ordinary top and no side curtains.

The rearmost windows are held in frames which can easily be put in place and fixed by screws, this protecting the tonneau seat from side drafts. To attach the door windows a few screws are run vertically into sockets on the top edges of the doors and into the body side piece between the doors, the parts to which the windows hinge being also attached to the roof frame. An ingenious idea is the use of thin pressed metal troughs which connect the bottom edge of each window piece with the top edge of each door. As the windows and doors swing on different hinges a gap opens between the two as the door is opened and there is risk of pinching a finger between the two when closing the door again. The metal trough closes this crack and removes the danger while also assisting to keep out driving rain.

All around the top is a narrow leather flap which covers the junction and closes any crack, while the weight rests on felt pads which prevent injury to the paint. Inside the finish is in cloth or Bedford cord so the appearance is handso To give ventilation the tonneau windows are divided and top half can be lowered instantly. There is no part whicl flimsy or rattlesome.

The King company has arranged with the makers of the to supply King dealers at a special price, and it is underst that the top is attachable to any model D touring car. weight is stated to be about 175 lb., or about 100 lb. n than a folding top.

—

261,860 Cars Have Electric Systems Other Statistics

EAST PITTSBURGH, PA., Aug. 14—Some interesting tistics have been compiled by G. Brewer Griffin, ı ager of the automobile equipment department of the Wes house Electric & Mfg. Co. in regard to the car and ligl and starting equipment production.

Mr. Griffin states that 261,860 cars have been equi with electric lighting and starting, while the total produ in this country during the last calendar year was 611 valued at $380,000,000, at an average dealers' valu $621.50 per car. Of this production 350,000 are count Fords, worth $136,500,000. The total value of elec equipment is given at $10,354,570.

Other statistics cited by Mr. Griffin are estimates o terials used in 1915 cars. These are: 670,000 tons of cated steel; 4020 tons aluminum and alloy; 2141 tons r factured brass; 1068 tons curled hair; 2050 tons moss; hides, or one-third hide per car; 3,280,000 sq. yd. imi leather, or 8 yd. per car; upholstery fittings such as tape, etc., worth $917,542; 6,560,000 yd. burlap, etc.; 1 250 yd. top materials and linings worth about $2,44 7950 tons manufactured cotton used in tires on new 300,000 lb. sheet celluloid; 9338 tons rubber and comp 2,446,780 pairs of hinges; and the same number of door fittings; 489,356 sq. yd. carpet for tonneau; 642,908 linoleum for running and toe boards; 8,450,850 boa manufactured hickory and other woods for floors, bodies, etc.

In the starting, lighting and ignition industry alo Griffin states there are between 9000 and 10,000 peop ployed.

The Export Opportunity

IT is to be questioned whether manufacturers who refuse preferred orders from abroad for the sole reason that their output is already booked up to American dealers are not short sighted. At the present moment there is a large unsatisfied market just across the Atlantic and a manufacturer with a suitable car has a chance to make a foreign reputation that never will be repeated. When the automobile is suitable to the needs of the British or French market and a good foreign dealer comes along with his money in a bag it would surely be worth while to disappoint a few home dealers by reducing the number of cars they can secure by half a dozen or so, in order to get a footing over seas.

When hard times strike the home trade as one day they must do, the manufacturer with a substantial foreign connection will be in a much better position than a man who depends solely upon home trade.

This applies to parts makers as well as to manufacturers of complete cars, for it is obvious beyond all question that the British automobile trade are ready and anxious to buy in America what formerly they obtained from France and Belgium, and to buy more extensively, too. Had the home trade slumped this year the foreign demand would have still made 1915 a wonderful year, and, however insistent the American demand for cars and parts, the foreign market must not be neglected.

Light Weight Unanimity

THE consensus of engineering opinion that light weight chassis will be the next big development in automobile construction is remarkable. Lately the subject has been much under discussion and there is scarcely a man to be found now who sticks to the old argument of the heavy car. There used to be many who maintained for divers reasons, that high power and great weight produced a better car, where upkeep was not considered, than lesser weight and correspondingly lesser power. This notion is breaking down altogether and some engineers go so far as to predict the speedy demise of the 4000-lb. automobile.

The immense general interest in the subject among all branches of the trade and also in automobile clubs and places where users of car mostly congregate suggests that development along this line will be even more rapid than was at first anticipated. It suggests that the large, light car will soon be here in quantities and that every sale room will have to be equipped with a weighing machine before very many months have passed.

To multiplicity of cylinders, to automatic gearshifts and similar developments objections can be and are raised, but it seems the common sense of light weight is to have no antagonists.

Why Black?

WITH the time of the year when new models are settling down into regular production it is to be noticed that a few manufacturers are breaking away from the black finish that lately threatened to become universal. Of course, the reason for using black in the first place was that it was cheaper than a color and a little black enamel has a great covering power, but black is the very worst paint that could possibly have been chosen for automobile finishing.

Firstly, black shows the tiniest speck of mud or dust long before any other color and two cars starting out in the morning, one black and the other gray, will look totally different at the end of the same run. In a day's use in a town, even in good weather, a black car loses its freshly washed appearance almost at once, and by the afternoon it is dingy. On the other hand, a gray or blue, or brown, even a dark green or a maroon tint, will look fresh for days together.

Then again black is dependent absolutely upon its varnish, for without the gloss it rapidly takes on a rusty tinge like a hobo's coat, which no washing will ever remove. A colored car looks its best, of course, when the varnish is new, but when it has eventually gone dull it still lacks the seedy appearance of old black; it still looks fresh after a wash and the owner's pride in his car is generally more lasting. What's the use in washing a car that looks none the better for it?

The days of bright colors are gone perhaps; some yearn for brilliant reds and yellows, but good neutral tint browns and grays that both look well and wear well ought to be considered by manufacturers much more than they have been.

White to Increase Stock $3,000,000

New Issue to Pay 7% War Truck Orders Render Extension of Plant Necessary

CLEVELAND, OHIO, Aug. 16—The White Co., this city, will issue $3,000,000 new stock, according to an announcement made to shareholders. The greatest percentage of this new money, it was said, will be used for plant extensions, made necessary by war truck orders.

Although its operations are veiled with great secrecy, the White Co. is known to have been one of the heaviest makers of automobiles for war purposes.

To Retire Preferred

The present capitalization is $500,000 preferred and $2,440,000 common. The preferred will be retired immediately at $115 a share plus accumulated dividends until Nov. 1 next, or 3½ per cent.

The new issue of the $3,000,000 preferred will pay 7 per cent and will be sold to present stockholders.

—

Enger 12 at $1,085

CINCINNATI, OHIO, Aug. 16—The Enger Motor Car Co. of this city has brought out a twelve-cylinder motor which is manufactured in the conventional twin-six V-type design. The dimensions of the power plant are 2⅝ bore by 3½ stroke. The valves are in the head and the cylinder heads are removable. Other specifications of the car include 115 in. wheelbase, cantilever springs, streamline type bodies and 32 by 4 tires. The list price of the car is $1,085.

—

Waverley Electric Price Reductions

NEW YORK CITY, Aug. 13—The Waverley Co., Indianapolis, Ind., will increase its 1916 production to 2000 cars, or approximately 100 per cent. A result of this proposed production is a general lowering of prices ranging from $1,000 to $500, effective Aug. 1, last. The following list gives the former and new prices:

Model	Old Price	New Price
108-5-Pas. Limousine	$3,500	$2,500
Roadster Coupé	2,000	1,750
109-Four-Chair Brougham	2,750	2,500
104-Front-Drive Four-Pas. Brougham	2,400	2,000
105-Rear-Drive Four-Pas. Brougham	2,350	1,900

—

New Empire Four at $895

INDIANAPOLIS, IND., Aug. 16—The Empire Automobile Co., which recently announced a six-cylinder model at $1,095 has in addition a new four-cylinder car which displaces the previous four. The new model lists at $895 and has a new power plant consisting of a 3⅞ by 5 T-head motor fitted with Connecticut ignition and a Schebler carbureter, a cone instead of a disk clutch and a three-speed gearset. The rear axle is practically the same as that of the former four but the tires now are larger, being 33 by 4 instead of 32 by 3½. The body is an entirely new one, the wheelbase is 112 in.

—

Driggs-Seabury Ordnance Co. with $4,000,000 Capital

NEW YORK CITY, Aug. 14—The Driggs-Seabury Ordnance Co., incorporated in Delaware last week with $4,000,000 capital stock, will take over the control of the old Driggs-Seabury Ordnance Corp. The company's capital consists of $500,000 first preferred stock, $500,000 second preferred stock, and $3,000,000 common. It is understood that the common stock will be put on the curb to-day by Herrick & Bennett. The preferred stocks will not be offered to the public.

The incorporators are C. M. Egner of Elkton, Md., H. L. Mullin and N. P. Coffin of Wilmington, Del.

The new company will take over the entire plant and assets of the corporation and will at once resume the manufacture of trucks and other war munitions and will take over the manufacture of about $600,000 in truck parts, contracts for which were held by the corporation.

Borie for President?

It is understood that E. A. Borie, formerly vice-president of the Bethlehem Steel Co. is slated for the presidency of the newly organized company. Strong New York interests, among which is the banking firm of Wm. Morris Imbrie & Co., are connected with the new organization. The board of directors have not been announced, but the operating end of the business will be in the hands of former officers of the Bethlehem Steel Corp. The latter company states that it is not trying to buy out the Driggs-Seabury Ordnance Co., as rumored.

—

Woman Takes Chalmers Distribution for France

NEW YORK CITY, Aug. 13—The Chalmers Motor Company has announced that Helene Dutrieu, a prominent French aviatrice, has been appointed Chalmers distributor for all of France.

—

Hughes Falcon Chief Engineer

DETROIT, MICH., Aug. 14—W. S. Hughes has been appointed chief engineer of the Falcon Motor Truck Co. He was with the Findeisen & Kropf Mfg. Co., manufacturer of Rayfield carbureters, during the past five years, being with the Detroit branch during the last two years.

Coffin and Riker on Navy Board

Elected by Secret Mail Ballot of S. A. E. Members from Six Candidates

NEW YORK CITY, Aug. 18—At the headquarters of the Society of Automobile Engineers it was announced to-day that the successful candidates for election to membership on the naval advisory committee are A. L. Riker and Howard Coffin. The counting of mailed votes for the six candidates was made yesterday.

A. L. Riker is vice-president of the Locomobile Co. of America, Bridgeport, Conn., and is actively in charge of the engineering policies of this concern.

Howard Coffin is vice-president of the Hudson Motor Car Co., Detroit, Mich., and directs the engineering work of this company.

Mr. Riker was the first president of the Society of Automobile Engineers, serving for three terms. Mr. Coffin became S. A. E. president in 1910, and was the originator of the movement which has resulted in its great increase in size and activity since that time, the standardization of materials and parts being prominent examples. Both men have recently done effective work on the Membership Committee, the Finance Committee and the Miscellaneous, Electrical Equipment, Frame Sections and Nomenclature divisions of the Standards Committee.

Mr. Riker and Mr. Coffin were the directing officials of the mechanical branch of the Association of Licensed Automobile Manufacturers.

Mr. Coffin was educated in the engineering department of the University of Michigan. He served 5 years in the postal service. From 1902 to 1905 he was chief of the experimental department and chief engineer of the Olds Motor Works. In 1906 he was vice-president and chief engineer of the E. R. Thomas Detroit Co. and consulting engineer of the E. R. Thomas Motor Co. Subsequently he became chief engineer of the Chalmers-Detroit Co. and the Chalmers Motor Co.

Mr. Riker is an electrical as well as mechanical engineer. As early as 1888 he devoted attention to electric motors with a view to developing a type suitable for vehicle propulsion. It is understood that the Riker Electric Motor Co. produced the first toothed armature. Its first electric vehicle was brought out in 1894. In 1900 Mr. Riker built 5-ton electric trucks. He has been vice-president of the Locomobile Co. for 13 years. In 1900 he was awarded by the French Government a medal for car design.

Stearns Has Knight V Eight

3¼ by 5 Motor to Be Mounted in 123-In. Chassis—Five Body Types

CLEVELAND, OHIO, Aug. 17—An eight-cylinder V Knight motor has been added to the Stearns line and incorporated in a chassis which follows the line of the Stearns four described in this issue of THE AUTOMOBILE. The development of this type of motor is of interest due to the difficulty attached to the design of a V Knight motor and the resulting product has been made exceptionally clean. The engine has a fairly long stroke in proportion to bore, the dimensions being 3¼ by 5. The chassis in which the motor is fitted and the wheelbase of 123 in. and the body styles will include a seven-passenger touring, three-passenger roadster and a four-seated coupé. Limousine and landaulet bodies will also be marketed.

The new Stearns motor is the result of the experience gained after the construction of several experimental models. There are two eccentric shafts situated close together in the V, this position being the same as that usually occupied by the camshaft in a poppet engine. For driving these eccentric shafts a silent chain is used, but this drives one only, the second shaft being driven from the first by a spur gear. The gears are, of course, of same size, and are contained in a small chamber cast in the front end of the crankcase so that they can be used as the oil pump and they are naturally wide enough in face to deliver a large supply of lubricant at a high pressure.

Oil goes to a hollow crankshaft 2¼ in. in diameter and is thence taken to every point as the connecting-rods are hollow and serve as leads to the piston pins.

There is a double carbureter, and this is situated in the V, the exhaust manifolds being on the outside of each cylinder block, which makes for convenience and neatness. For electrical equipment a Westinghouse double unit system is employed and there is also a Remy distributer for ignition.

Side-by-side connecting-rods are employed after experiments with the forked type in conjunction with other experiments with the arrangement adopted, and the cylinder blocks are staggered 1½ in. to allow for the rod layout.

—

Locomobile Grants 8-Hour Day and Withdraws Profit-Sharing

BRIDGEPORT, CONN., Aug. 12—The Locomobile Co. of America has granted an 8-hr. day to its employees and has withdrawn its profit-sharing plan. Fifteen hundred employees of the company at a mass meeting accepted a settlement with the company and will not go on strike. The company granted the demands made by the employees, with some exceptions. The new time schedule goes into effect Aug. 30.

The company did not agree to the demand that all hours over eight a day, or forty-eight a week, should be considered overtime, to be paid for at time and a half. The company will pay time and a half over 10 hr. a day. The men state that they will adjust that difference by refusing to work over 8 hr. a day. Night hands will not work more than 48 hr. a week and will receive a bonus of 15 per cent for that work. The wages for 48 hr. piece work will be the same as 55 hr.

—

Haynes Gets Restraining Order Against Sun Co.

BUFFALO, N. Y., Aug. 14—The Haynes Automobile Co., Kokomo, Ind., has been granted a temporary restraining order by the Circuit Court of Erie County, N. Y., August 12, restraining the use of the Haynes name in connection with that of the Sun light six, to be made by the Sun Motor Co., this city.

—

Bosch Gives Higher Wages

SPRINGFIELD, MASS., Aug. 12—The Bosch Magneto Co., employing about 1000 men, will put into effect on Sept. 1 an 8-hr. day instead of 9½ hr., as at present. Piece work wage schedules will be increased, so that the employees will receive as much for 8 hr. as they are now getting for the longer day.

—

Spicer Machinists Demand 8-Hour Day

PLAINFIELD, N. J., Aug. 12—At a meeting of the machinists employed by the Spicer Mfg. Co., it was decided to give the management until to-morrow to grant an 8-hr. day, on pain of a probable strike. Seven hundred men are affected.

—

Standard Welding Co. Expands

CLEVELAND, OHIO, Aug. 17—The first addition to the Standard Welding Co. plant is nearly completed. It is a brick building 100 by 200 ft. facing West Seventy-fourth Street. This building is to be devoted entirely to the manufacture of bent tube parts.

The second addition is to be of the mushroom reinforced concrete type built in the form of an L. One leg will extend 200 ft. north and south on West Seventy-third Street, the other leg 240 ft. east and west from West Seventy-third to West Seventy-fourth Street.

Later two more additions will be built parallel to the Seventy-third Street section and connecting with the main building. Double railroad sidings will enter between each section, giving excellent shipping facilities.

Detroit Plants Run at Capacity

Many English Dealers Want Cars—Retail Sales Recover from Slack Condition

DETROIT, MICH., Aug. 16—There was little change in the manufacturing and sales conditions of the manufacturing field of this city nor of the local selling of cars during the past week. Manufacturers are all running full tilt, and dealers say that the territory served by this city is in healthy condition, with a pleasing contrast to the war and panicky conditions which affected business for the corresponding period of last year immediately following the declaration of the great conflict.

It is rather a surprising fact that there are so many of England's representative dealers in cars in this country at this time, but they are here with the sole intent of buying cars, and they have plenty of money to buy them with. Naturally they come immediately to Detroit, and there were several Englishmen in the city last week seeking to place large car orders. In fact the English field is strongly demanding Detroit vehicles, but they are hard to get, so tied up are the factories with domestic business at this time.

While the rainy weather conditions which have prevailed most uniformly all over the country were somewhat improved last week, allowing the resumption of the dealer crusade, the slackening of retail sales which this weather necessarily was responsible for was only temporary, for with the coming of more sunshine the rush is on again, if indications as echoed here are any criterion. In fact, the weather has had no slackening effect upon the activities of the factories, which are still as pressed as ever since the opening up of the season.

Raw Materials Scarce

There is one aspect of the business situation with the Detroit plants that bids fair to becoming a serious thing if the resourcefulness and business acumen of the motor car fraternity do not find some way of getting around it. That is the growing shortage of certain of the raw materials that are all important to the car maker and the parts and accessory manufacturer as well. Take iron and steel, for instance. The war orders and war business with the suppliers of these materials have curtailed greatly the supply which they have for domestic trade, and prices are bound to be affected by this dearth of the requisite materials. Iron castings are becoming harder to get, as well as those made from other metals.

Detroit Plants Need Workmen

Great Shortage of Skilled Labor Prevents Many Factories from Capacity Work

DETROIT, MICH., Aug. 14—There is still a great shortage on skilled labor in the local automobile and parts manufacturing concerns. Notwithstanding advertisements in local and out-of-town papers and standing orders with employment agents, many plants are not being run to full capacity on account of their inability to get all the men they need.

Under normal business conditions it would be possible to get these men, but since so many manufacturers outside of the automobile industry have started to make what is generally termed war materials for the European countries these concerns have been enlarging their plants and increasing their production, and in adding new men have given the preference to those formerly connected with the automobile industry. In fact, it is reported that agents from such manufacturers, also employment bureaus, have been offering increased wages to men now employed in local automobile and parts factories.

Advertise for Workers

The Packard Motor Car Co, which now has 8200 men on its pay roll, which is the largest number in its history, has been advertising for the last five or six weeks for such workers as all-around machinists, hand and automatic screw machine operators, drill press and milling machine men, drop-forge hammer men and heaters, J. & L., Gisholt and P. & J. operators, tool makers, panelers.

The Continental Motor Mfg. Co. has been advertising for tool and crankshaft lathe hands, grinders, punch press operators, J. & L. and hand-screw machine operators, block testers and braziers.

The Chalmers Motor Co. wants tuners, first-class machinists for experimental department, inspectors and electricians, lathe hands, W. & S., B. & P. & W. screw-machine hands, Lanis grinders, cutter grinders, Acme, Cleveland and Gridley automatic-machine hands.

The Russell Motor Axle Co. needs rear-axle assemblers. The C. R. Wilson Body Co. needs body finishers, door hangers, wood milling machine men.

The Maxwell Motor Co. has been advertising for weeks for tool makers, tool lathe hands, screw-machine operators, P. & J. operators, crankshaft lathe hands, inspectors.

The Auto Parts Mfg. Co. requires Healy cylinder grinders and Gisholt men. The Sterling Motor Co. is advertising for bearing scrapers and motor assemblers.

The Kelsey Wheel Co. needs B. & O. operators. The Rands Mfg. Co. desire experienced windshield assemblers. The Briscoe Mfg. Co. needs more die makers. The Fisher Body Co. is in need of No. 1 aluminum panelers on enclosed bodies. The American Auto Trimming Co. is in need of final assemblers, applying hardware on finished bodies. The Detroit Nut Co. has room for B. & S. automatic screw machine operators and machinists.

At many other plants, such as Dodge Bros., the Cadillac Motor Car Co., the Hayes Mfg. Co., and the Briggs Mfg. Co., it was stated that men are being added to the force when found to be skilled workers in the kind of work for which they apply.

—

Homes for New Employees Pontiac Manufacturers' Problem

PONTIAC, MICH., Aug. 13—At a meeting of many of the city's business men, especially manufacturers or their representatives, it was recognized by all that something will have to be done quickly to meet the urgent local requirements for more houses for workingmen, otherwise the expansion of the manufacturing concerns may be halted.

1000 to 1200 More Men

Briefly stated, between 1000 and 1200 more men will be employed by the plants this year, and according to an investigation, out of 176 houses found available only fifty-one were found to be up to date, modern and entirely acceptable, while fully 20 per cent were undesirable.

Such men as Charles B. Wilson, president of the Wilson Foundry & Machine Co.; W. D. Kelly, factory manager of the Oakland Motor Car Co.; W. L. Day, vice-president and general manager of the General Motors Truck Co.; O. J. Beaudette, president of the O. J. Beaudette Co., and many others spoke earnestly about the conditions and made it plain that the city and its citizens must get together and do something at once. A suggestion was made for the formation of a stock company which would build at least fifty houses which could be rented at $20 a month or less or sold on monthly payments.

—

Fifty Oldsmobiles a Day

LANSING, MICH., Aug. 12—Reports received at the Olds Motor Works from its distributers and dealers show that business is far ahead of last season in practically all the country. It means that production will have to be increased. At the present time, in fact for some time, fifty four-cylinder cars have been the average daily output, and this schedule will be maintained indefinitely. Production on the eight-cylinder car will materially increase the daily output.

N. Y. Sales Continue To Gain

Dealers Begin To Get Calls for Enclosed Bodies—Some Are Sold Out

NEW YORK CITY, Aug. 17—Good weather and the return to the city of vacationists were responsible for a brisk sale of automobiles last week. The dealers report that sales are remarkably large, when it is considered that the month of August has been in former years a poor month. Many inquiries are coming in now for winter cars and a few of the dealers are making sales in closed cars.

A number of the dealers are at present doing no business, being completely sold out, some of them as far back as five weeks. A few of the low-priced agents have been waiting nearly two weeks for deliveries of the 1916 models and report that without even a demonstrator, they are making large sales.

Harry S. Houpt, the Hudson dealer, has set a sales record, his books showing that he has disposed of more than 500 cars since June 10. C. T. Silver, president of the C. T. Silver Motor Co., Overland dealer, reports that he has recently lost a number of sales owing to his inability to make delivery immediately to persons who wanted to drive the cars away from the showroom. He expects to be able to make fairly prompt deliveries in a week.

Some Make Bonus Offers

The Briscoe agent was sold out five weeks ago and is waiting for the 1916 cars. Buick has every car sold for two months. This agency reports that if it could get immediate deliveries, fifty to sixty cars a day could be sold. Buyers are so urgent in their demand for cars that a number of them are making large bonus offers to procure cars.

Sales this week are heavier than ever and the floors of the agencies, especially in the low- and medium-priced cars, were crowded with prospective buyers. A number of the dealers with high-priced cars were also busy last week. Simplex reports good sales and is sixty-five cars ahead in sales. It is just beginning deliveries. The Pierce-Arrow agency, which has a few cars on hand, had quite a number of inquiries for cars last week. Sales are normal. The Packard company is completely sold out.

The Mitchell agency reports good sales during last week. It is fifty-two cars behind in orders. Many inquiries are coming in on closed cars. Last week twelve closed cars, with specially built bodies, made in this city, were sold.

The Maxwell company has just received a fresh shipment of cars. Sales

for the month will amount to over 100 cars. Sales for last week up to last Saturday amounted to twenty-nine cars. The company is expecting a large business in September when a majority of the automobile buying public will have returned from the summer resorts.

Even now there are a large number of people who want cars for summer touring. The dealers report that motorists this year are using their cars more than ever for vacation purposes and state that in general this is responsible for some of the large sales records.

—

Sales Good in Missouri and Adjoining States

ST. LOUIS, MO., Aug. 9—The great majority of automobile dealers in the St. Louis district—including Missouri and its adjoining States—found business during the last week ranging from "Normal" to "Best in the history of the industry." A few reported a slackening in the rush for cars—due chiefly to the fact that farmers are too busy harvesting to find time to spend their rapidly accummulating wealth—but even these dealers said all indications pointed to unusually heavy sales in the near future.

Moon 33 per Cent Gain

The Moon company claimed a 33 per cent increase over last year's business and said conditions were especially rosy in the northern parts of the Central States. "Our only trouble," the sales manager said, "is in getting parts fast enough. We have more orders than we can fill now.

The Maxwell dealer here said, "Never in my life have I seen the automobile industry so healthy. We are working day and night filling orders."

The Federal Truck distributors said they were doing 400 per cent more business now than during a similar period last year. The Hudson-Phillips and Chalmers people enjoyed normal business.

—

Inter-State Behind Orders

INDIANAPOLIS, IND., Aug. 13—Increasing orders for Inter-State automobiles has caused the factory at Muncie to be 300 cars behind and will necessitate the doubling of the present force of workmen, numbering several hundred. It is hoped to have 300 new men at work by Sept. 15. Lack of workmen because of the great demand for them created by automobile parts companies and others engaged in supplying automobiles and accessories to the allies in the European war, has delayed the Inter-State company from increasing its production as rapidly as it had desired. All shipments to dealers are now pro-rated. Part of the increased demand, also, is due to the drop in price from $1,000 to $850.

Kelly-Springfield Tire Rushed

—

Is 27,000 Tires Behind Orders —Will Earn 27 to 30 Per Cent on Common

NEW YORK CITY, Aug. 14—The Kelly-Springfield Tire Co. is now 27,000 tires behind orders. As the company manufactures between 1000 and 1100 tires a day, this means that it is approximately a month behind orders on its books. The Akron, Ohio, plant continues to operate at capacity, and officials say that business on hand in sight insures a continuance of this rate of operation throughout the remainder of the year.

The company recently entered the truck tire field. By the first of the year it is estimated that it will be possible to make 400 truck tires a day. Enlargement of the plant in order to make this a possibility is now under way. These tires will sell from 10 per cent to 15 per cent higher than the average truck tire.

The directors estimate a rock-bottom earning of about $1,500,000 for 1915. Allowing for the difference in dividends after conversion of preferred into common this would mean close to 27 per cent for the common shares. Net may run as high as $1,700,000. It is expected that the company will distribute a substantial extra cash dividend this fall.

—

Record July Shipments of 12,515 Carloads

NEW YORK CITY, Aug. 14—Continued heavy demand for automobiles is reflected in the traffic statistics of the National Automobile Chamber of Commerce. The figures indicate shipment of 12,515 carloads in July, compared with 4870 carloads in July last year. These figures easily establish a new high record for automobile shipments at this season and the railroad earnings on this traffic are now well over $1,000,000 a month.

—

Pontiac Plants Rushed—Unfilled Orders Large

PONTIAC, MICH., Aug. 13—According to a statement made by W. D. Kelly, factory manager of the Oakland Motor Car Co. that concern now has orders for 11,000 cars all of which are to be ready for shipment by Jan. 1, 1916. There are 511 men on the pay roll now and the force is to be increased by at least 200.

Orders for 500 Trucks

W. L. Day, vice-president and general manager of the General Motor Trucks Co. stated that the company has orders now for at least 500 trucks and that the number of unfilled orders on the books is greater than the total number of trucks shipped during an entire year during any year except the fiscal year just ended. This past year has been the best in the history of the company and showed after all bills had been taken care of a net balance of $250,000 in the treasury. The company will add 100 men.

The Wilson Foundry & Machine Co., according to president Charles B. Wilson, will eventually make all the cast iron and machined parts for the Willys-Overland Co., Toledo. During the week the company acquired further land bringing its total up to 21 acres. Mr. Wilson stated that just as the Willys-Overland Co. grows so it will be with his concern, and every further expansion of the Toledo concern will mean a further needed expansion of his company. The Wilson company will add 600 men.

The American Forge & Socket Co., a new concern, is to employ seventy-five to 100 men.

Other Concerns Increase Forces

The Hess-Pontiac Spring & Axle Co. which added about 150 men recently will need at least fifty more. A score of other concerns are also adding or will add more men to their force.

—

Northway Motor to Double Space

DETROIT, MICH., Aug. 14—Additions now being erected, together with a new building not yet started, will eventually double the floor space of the Northway Motor & Mfg. Co. and bring the total up to 450,000 sq. ft. When completed the working force is to be increased, and it is said that about 4000 men will then be on the pay-roll.

—

Velie Factory at High Speed

MOLINE, ILL., Aug. 13—Changes are being made at the factory of the Velie Motor Vehicle Co., Moline, Ill., to facilitate increased production.

The six-story building heretofore used for storage purposes will now hold the final assembly departments and shipping rooms. With this new arrangement rough material is received at the west end of the main plant and finds its way through the machine shop, first assembly and test, hence to the final assembly, where the bodies await installation after which the completed cars are shipped without delay or further handling.

All Velie factories in Moline are working overtime. The truck factory is handling two large European orders for heavy-duty trucks.

—

Oldsmobile Sells Buffalo Branch

BUFFALO, N. Y., Aug. 14—The Buffalo branch of Olds Motor Works, has been bought by Louis Engel, Jr., who will conduct the business under its former name, the Oldsmobile Co. of Buffalo.

200 Per Cent Gain in Los Angeles

Arizona and Southern Cal. Agents Order Carloads—Allotments Dwindle

LOS ANGELES, CAL., Aug. 10—Heat seems to be a stimulant to the automobile industry in Southern California. The opening days of August, the hottest of the year, have brought a great increase in the car sales of Los Angeles, Southern California and Arizona.

100 per Cent Gain for Week

The total business of the representative Los Angeles dealers shows a gain of more than 200 per cent for the first week of August, 1915 over the first six working days of August, 1914. An increase in business of almost 100 per cent is reported for the first week in August of this year over the first week of July.

Almost 600 Maxwells have been sold by the Lord Motor Car Co., since the new car was announced here Aug. 1. Six carloads arrived in Los Angeles, Aug. 8, were unloaded and delivered early the following morning, leaving the agency without a car except the two demonstrators which arrived the day before the announcement of the new models was made in this city. The suburban dealers are ordering cars in great numbers. In one day, Aug. 9, six carloads were ordered over the wire by agents in Arizona and Southern California towns.

The Los Angeles Ford plant is working hard to keep up assembling on an average of fifty cars a day.

The run on the new Overland continues. Since Aug. 1 forty cars have been delivered by the J. W. Leavitt Co., in this city and if the cars had been available, the local manager, L. V. Starr, claims that he could have delivered eighty or 100 machines. The new Willys-Knight has in no way affected the sales of the Overland. Twenty-nine of the new Knight machines have been delivered in this territory since Aug. 1.

The Packard Twin-Six has made a hit in Los Angeles. The demonstrator has not been in service here quite two weeks, yet more than a fourth of the entire allotment for Southern California 200 cars have been sold by Earle C. Anthony, although no deliveries can be made until about Sept. 10.

400 Orders Behind

The Howard Automobile Co., Los Angeles Buick dealers, is 400 orders behind now. The company is making deliveries right along through its subagents and at the main salesroom in this city, but the cars sell faster than they can be shipped out from the factory.

The new Cadillac reached Los Angeles to-day. The 1916 model caused almost as great a sensation as the arrival of the first "eight," more than nine months ago.

The Reo is being well received in the suburban cities. Earle C. Anthony contracted for 1500 cars for the entire State this season and with five carloads going at wholesale during the past two weeks, just to the Southern California sub-agents, it begins to look as if the 1500 cars will not be enough.

Dodge Bros. car is one of the most popular in Southern California at this time. Harold L. Arnold, Los Angeles dealer, has sold and delivered 586 Dodge cars since Jan. 1 and eighty-one cars this month.

Hawley, King & Co. have sold twenty-five more Oakland cars already this month than during the first half of July. Wm. R. Ruess, Stearns-Knight and Mitchell distributor, has sold eighteen cars in the past seventeen days. Ralph C. Hamlin has sold seven more Franklins and five more Scripps-Booth machines the first ten days of this month than during the first ten days of July. The Enger dealers, Irving Motor Car Co., sold three more cars this month than during the same ten days of last month.

Truck Sales Brisk

Truck sales have also been brisk during the opening days of August. Last month nine Mack trucks were sold during the first ten days. This month the Mack Motor Truck Co. has sold fourteen trucks.

The Studebaker Corp. sold 150 cars at retail in Los Angeles for the month of July and with fifty cars sold during the first ten days of August, this month promises to be the best in the history of the branch here.

Holley Business Better

DETROIT, MICH., Aug. 14—In comparison with business during the first half of 1914 Holley Bros., carbureter manufacturers, report that their business thus far this year has been twice as heavy. Conditions are better all around, and the outlook for the future is excellent. The plant will be running to its full capacity for an indefinite period.

—

Kelsey Wheel Adds

DETROIT, MICH., Aug. 14—The Kelsey Wheel Co. has now under construction additions which will increase its plant by nearly 80,000 sq. ft. of floor space. Officials of the company say that business thus far this year shows an increase of more than 25 per cent over the corresponding period in 1914. From reports received by the company from all parts of the country indications point to a banner year for the automobile industry as well as the allied industries.

70 Morton Tractors to Russia

Many Orders on Hand—U. S. Army Officials Test Machines —Plant to Be Enlarged

HARRISBURG, PA., Aug. 13—The Morton Truck & Tractor Co., this city, has completed and now has on the sea to Russia seventy tractors, which is a small part of an order received several months ago from the Russian Government. The tractors, which left New York last week, are of 60-hp. rating, weigh about 6 tons each and are capable of making from 2 to 10 miles an hour with a draw-bar pull of 8,500 lb.

Many Orders Going Through

This is the first shipment of an original order of 300 of this style of tractor, and there is now in course of construction at the local plant eighty 3-ton Morton trucks for the same government, as well as seventy-five high-powered armored cars capable of carrying two machine guns mounted on revolving turrets and an assignment of six men. The company also has additional orders for 80 and 120-hp. tractors, and for many more motor trucks from both the Russian and French governments, while the United States Government engineers have been inspecting the work of both tractors and trucks.

Th armored cars which are now being constructed have a six-cylinder motor of 125 hp., and are of the regular Morton type. While in London during the winter Robert L. Morton designed the armored car after the needs expressed by representativs of the Russian government.

Carry Two Guns, Men and Supplies

In addition to carrying its two guns and men the cars carry 50 lb. of ammunition for each gun and the necessary spare parts to keep the cars in active service. The guns and men are protected by armor plate of a thickness capable of withstanding nickel bullets of muzzle velocity of 2750 ft. per second at a range of 15 yd. Tests of various steels, both in this country and abroad, were made, and a special heat-treated steel of the Pennsylvania Steel Co. proved the most satisfactory. In the tests this steel withstood fourteen shots within a 3-in. circle, while most of the other steels were pierced or cracked.

Factory Increased

The plant of the Morton company has been greatly increased, and negotiations are now on for more grounds for additional buildings. Day and night forces are working, and the big orders have

made it one of Harrisburg's leading industries.

The tractors and trucks have many features, the most prominent being the four-wheel double-worn drive, with the flexibility of the four wheels under uneven road conditions. The worm is self-contained in the axle case, with its universal joint within the worm on the tractors, allowing great flexibility and full drawing power from all wheels. There is an automatic stop for the engine steel, and the trucks are equipped with both engine and hand steeling devices.

Foreign government officials are almost constantly at the local plant conducting tests of the finished tractors and trucks, and every machine finished has more than met with all the requirements asked by the visiting officials.

To Build Studebakers for Foreign Trade in Canada

WALKERVILLE, ONT., Aug. 13—Canada's automobile industry will receive a decided impetus through the decision of the Studebaker Corp. just announced, to build all its cars for the foreign market in its Canadian factory in Walkerville. This decision means the employement of several hundred skilled workmen and the operation of the Canadian plant to full capacity during the entire year. Heretofore Studebaker cars for the foreign trade have been built in Detroit, but an investigation proved that this branch of the business could be carried on much more economically and efficiently from Canada, and as a result, the output of the Studebaker factory in this town will be multiplied several times. Already work has started on fitting up the Canadian plant to meet the increased demand, and in a short time upward of 500 men will be employed. New traveling cranes and air compressors installed, rubbing decks and finishing rooms built and railway sidings re-arranged and increased.

—

Wetmore Laboratories for Test Work

MILWAUKEE, WIS., Aug. 14—The Wetmore Mechanical Laboratories Co., Milwaukee, has been organized with $20,000 capital to do inventive, research and test work for manufacturers. The concern intends to specialize in the development of motor car parts. C. P. Wetmore, until recently general superintendent of the Dial Cash Register Co., Milwaukee, and and an engineer of note, is at the head of the new company. A laboratory and machine shop will be established in Milwaukee on Sept. 1.

Kidd Paige Representative

DETROIT, MICH., Aug. 16—S. W. Kidd, formerly with the Briggs-Detroiter Co. has been appointed a district sales representative by the Paige-Detroit Motor Car Co.

Ford Averages 1027 Cars a Day

—

Total of 308,213 Built in Fiscal Year — Estimate 4,000 Daily Now Possible

DETROIT, MICH., Aug. 16—Based upon 300 working days for the year, the average daily production at the Ford Motor Co. during its fiscal year which ended July 31 was 1027 automobiles, as the company just announced that a total of 308,213 Fords had been built and sold between Aug. 1, 1914, and the end of July, 1915.

When the total output of the Ford company for its past year is analyzed it is obvious that, big as the total is, it is far from what the actual output of that concern would be when work is performed under pressure; that is to say, when day and night shifts and a full force of 20,000 men or more is working, as was the case in March, April and May.

2096 Cars in 1 Day

It was March 17 that the record production of 2096 cars in one day was established. A few days later 2026 were made. April there were also days when the 2000 cars a day schedule was maintained. The total for April was 46,510 cars, the biggest month in the Ford history. In computing these figures with the more recent activities at the plant it will be remembered that on July 16 car No. 300,000 of the 1915 output was completed. In the fourteen working days from July 16 to 31 the total output of Fords was 8213, or at the rate of only 586 cars a day, or 1510 less than the March record day and 441 less than the daily average for the whole past season.

Speaking on the subject of output, an official of the company said: "I believe that this year a production of more than 4000 cars in one day will be possible. No special effort was made during the past season when we reached the 2000 mark. It was merely a test to see what we could do under normal conditions. Furthermore, at that time few of our assembling plants were all working under full pressure. By Jan. 1 the production facilities will allow every assembling plant to assemble from seventy-five to 150 cars a day. Some of the plants, like Philadelphia, Los Angeles, San Francisco, Long Island City, Chicago, will be supplied with sufficient stock to turn out 200 or more cars a day. However, if such an output will be maintained for any length of time is something no one can predict. We are sure about one thing, and that is that we are in a position to meet any emergency in so far as producing cars is concerned. If we received an order for 50,000 cars to be completed in 2 weeks I have not the slightest worry that every one of them would be ready 24 hours before the day stipulated.

"There are two all important factors to be taken into account with regard to quantity production such as we turn out. First, the raw and other materials needed for such production, and secondly, the public demand.

56,000 Behind Orders

"There is no question that the Ford company could have and would have made and sold at least 25,000 more cars during the past season. As a matter of fact, there have been from 50,000 to 60,000 back orders on the books for the last six months. The one and only reason of not making as many cars as could have been sold was the lack of needed material. If present conditions prevail for any length of time not only the Ford company but many other concerns will be greatly affected in making as many cars as intended. The tremendous amount of war orders is taking precedent over everything else with the steel mills and other plants which furnish raw materials. The agents from the foreign countries are willing to pay any price to be served first and there are plenty of instances to be cited where the automobile manufacturers find that they have but little to expect, and must look elsewhere for their requirements."

From Five to 1027 a Day

The accompanying table will give a correct idea of the growth of production at the Ford Motor Co. since this concern has been in existence:

YEARLY OUTPUT OF FORD CARS

Year	Total Output of Cars	Increase or Decrease	*Daily Average
1903-1904	1,708	..	5
1905	1,695	— 13	5
1906	1,599	— 96	5
1907	8,423	+ 6,824	28
1908	6,398	— 2,025	21
1909	10,607	+ 3,209	35
1910	18,664	+ 8,057	62
1911	34,466	+15,802	115
1912	68,544	+30,078	228
1913	164,452	+95,908	545
1914	248,307	+83,855	827
1915	308,213	+59,906	1,027
Total 12 years	873,076		

*Based on 300 working days.

According to Ford salesmen, as well as to state registration records, it appears that 80 per cent of the Ford cars sold in 1915 were touring cars, 15 per cent were runabouts and the remaining 5 per cent consisted of town cars, coupelets and sedans.

$15,410,650 in Rebates

Based upon these percentages, the Ford company sold 246,570 touring cars having a total value of $110,819,300; 46,231 runabouts having a total value of $20,341,640 and 15,402 town cars, sedans and coupelets of an average value of

$800, or a total value of $12,341,600. This brings the total estimated value of the cars sold by the Ford company in 1915 to $143,502,540.

To the purchasers of the 308,213 cars sold during the past season, the Ford company will return as a rebate a total of $15,410,650.

—

$500,000 Ford Assembly Plant for Oklahoma City

OKLAHOMA CITY, OKLA., Aug. 13—The Ford Motor Co. will build a $500,000 fireproof assembly and service plant here to employ 300 men. Construction will begin in September. It will have 180,000 sq. ft. of floorspace.

Since the Ford company commenced doing business in Oklahoma, the company has enjoyed a fine business. Up to date, the company has sold 16,000 cars. Last year 4000 were sold, and according to J. M. Morriss, the assistant manager of the local branch, this branch could have sold 4000 more. The estimate for the next year, which dates from Aug. 1, has been placed at 11,500 for this State.

On the ground floor will be the 50 by 75 ft. display and salesrooms. At the rear of the salesroom will be the store room and garage, which will be 200 by 75 ft. The manager, assistant manager, and the head of the wholesale department will have private offices on the second floor.

Painting, upholstering, car assembling and storing of stock will use the entire third and fourth floors. An electric sign will top the building.

—

Chicago Sales Good Despite Severe General Rains

CHICAGO, ILL., Aug. 17—Reporting on trade conditions in Chicago, Reo has done 50 per cent more business this week than last, and in the first 2 weeks in August there was 100 per cent increase over the same period last year. Locomobile reports extraordinary business the past few weeks, about 50 per cent more than same period last year. Pierce-Arrow business is quieter now and has been since Aug. 1, because many customers are out of the city. Nothing was done last year at this time but a few sales are being made now. Dodge reports business not so active during the last 2 weeks on account of the severe general rains. Many dealers have cars on the floor which they cannot deliver on account of mud. Studebaker reports twice as many orders as at this time last year.

Nesbitt Directs King Advertising

NEW YORK CITY, Aug. 18—W. B. Nesbitt of the Ward & Gow Agency, New York, has been appointed advertising manager of the King Motor Car Co., Detroit. Ward & Gow have complete and exclusive charge of King advertising.

New Series Genemotor Is Out

—

G. E. Electric System for Fords Awarded Gold Medal at Coast Exposition

NEW YORK CITY, Aug. 14—A. J. Picard & Co., this city, general distributors of the Genemotor starting and lighting systems for Ford cars, manufactured by the General Electric Co., have completed their plans for the distribution of the new series Genemotor which has just been brought out. The Genemotor was awarded the gold medal at the Panama-Pacific International Exposition. The new series incorporates a number of improvements which are designed to make the system more reliable and to fortify it against the possibility of misuse in the hands of the novice.

Two particular improvements are to be noted in the new series, which is the second model of Genemotor offered since Jan. 1. These are a double-point contact relay and a flexible driving pinion which is designed to eliminate chain trouble. The new contact relay arrangement enables the generator to start charging the battery at a lower car speed than before; on high gear the battery starts charging with the new model at a car speed of 9 m.p.h.

The reduction of speed at which the battery charges is due to changes in the electrical characteristics of the Genemotor and also to the employment of the improved reverse current cutout, which has a double instead of a single contact. With the lower charging speeds drivers who travel at an average speed of 15 m.p.h. or less will not be troubled by a shortage of current available for operating their lamps.

The flexible driving pinion is a cushion sprocket much along the lines of that used during the past season, but improved in details of construction to provide smoothness and adjustability. The price remains $75.

—

Swan Carbureter Gets Medal

SAN FRANCISCO, CAL., Aug. 12—The Swan Carbureter Co. this city has been awarded the gold medal at the P. P. I. E. This is the highest award made to any carbureter exhibited there.

100 Chalmers Service Men in Annual Convention at Factory

DETROIT, MICH., Aug. 16—To-day and to-morrow over 100 of the service men of the Chalmers Motor Co. are taking part in the annual convention which is being held at the plant.

At to-day's meeting president Hugh Chalmers greeted the service men and talked to them on the Chalmers' 1916 policy and plans. Vice-president C. A. Pfeffer also greeted the visitors. Sales manager Paul Smith outlined the object and plans of the convention. Chief engineer C. C. Hinkley spoke about valve-in-head overhead camshaft motors. Service manager A. B. Hanson introduced the service men to the heads of the various divisions of his department and under the direction of vice-president in charge of works S. H. Humphreys, the service men made a tour of the plant. During the afternoon a trip to Grosse Pointe was taken and in the evening a dinner was served at the Ponchartrain Hotel.

Tuesday's session will open with a general discussion on service. This will be followed by a discussion of the Chalmers 6-40 motor which will be illustrated with practical demonstrations. Other speakers are to be A. Atwater Kent, president of the Atwater Kent Mfg. Co., Philadelphia; H. F. Willard, manager of agencies of the Willard Storage Battery Co., Cleveland; Frederick Purdy of the Findeisen & Kropf Mfg. Co., Chicago, manufacturer of the Rayfield carbureter; H. S. Barter, of Gray & Davis, Boston, will talk on the Gray & Davis starting and lighting system.

During the afternoon there will be an open meeting presided over by chief engineer Hinkley and in the evening a dinner and entertainment at the Ponchartrain Hotel.

—

Bondholders to Buy Speedwell Plant

DAYTON, OHIO, Aug. 12—Bondholders of the defunct Speedwell Automobile Co. have decided to purchase the plant when it is sold at public auction on Sept. 1. The plant will continue to be occupied by the Record & Computing Machines Co., which holds a 15-year lease on the property.

New Process Gear Buys Plant

To Take Over Monarch Typewriter Factory Oct. 1—To Employ Over 1000

SYRACUSE, N. Y., Aug. 17—The New Process Gear Corp. will acquire ownership of the Monarch typewriter plant, Syracuse, Oct. 1.

The buildings of this plant cover 2 acres and the surrounding land, which adjoins the property of the New Process Corporation, includes an additional 3 acres. The main building is five stories high, is of brick and slow-burning mill construction. After alterations the Monarch plant will be used by the New Process Gear Corp. as the job gear and axle and transmission department and present plant will be devoted exclusively to the manufacture of automobile materials.

It is the intention of the corporation to employ more than 1000 employees at once before spring, at which time the additional five-story building now being erected on property purchased recently will be completed and equipped.

—

277 More Cars for Delaware

DOVER, DEL., Aug. 13—The State of Delaware received 277 new registrations during the month of July, bringing the total number of cars in that State up to 4412, there having been 4135 cars registered up to July 1. The list of licensed owners and their cars, issued by G. H. Ellis, Secretary of State, shows that the Ford leads in number, followed in order by the Overland, Maxwell, Studebaker, Buick, Hudson, Cadillac, Pierce, Oldsmobile and Packard.

The following list gives the name of car and the number registered during the month of July:

Name	Number	Name	Number
Ford	68	Cadillac	7
Buick	21	Pierce-Arrow	7
Hudson	17	Paige	5
Overland	16	Oldsmobile	5
Maxwell	13	Packard	4
Studebaker	9	Mitchell	4

—

Maxwell Denver Service Branch

DENVER, COL., Aug. 13—The Maxwell Motor Co. has opened a distributing service branch in Denver at 1248 Broadway. The new branch is run under the name Maxwell Motor Sales Co. with D. S. Eddins as district sales manager, W. N. Lindberg as service manager and N. B. Walsh sent from the factory to take charge of the parts stock. Mr. Eddins formerly was in Texas for both the Maxwell and Studebaker people and Mr. Lindberg has been with the Maxwell concern several years, recently opened the company's new branch in Pittsburg.

The business will be under the general direction of Zone Supervisor John Yoke, who also has charge of the business in the Kansas City and Texas districts. This is one of sixteen branches being established by the company throughout the United States.
